[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996).

[4] Historic sediment metal concentrations are based predominantly on bulk sediment samples.

(Blue) Values is > TEL. Values shown in bold text also exceed both upper and lower Hazeltine Creek Historic 95th Percentile values.

(Orange) Value is > PEL. Values shown in bold text also exceed both upper and lower Hazeltine Creek Historic 95th Percentile values.

Table E.3: PCA results displaying; eigen value, percent variance explained, Monte Carlo randomization p-values of axis significance, and station scores for < 2mm sediment from Hazeltine Creek sampling stations, Mount Polley Mine, 2014. Data were Log (X+1) transformed prior to analysis [a].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.
[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.
[3] Contaminated Sites Regulation (Government of British Columbia 1996).
[4] Historic sediment metal concentrations are based predominantly on bulk sediment samples.

(blue) Value is > TEL. Values shown in bold text also exceed both upper and lower Hazeltine Creek Historic 95th Percentile values.
(orange) Value is > PEL. Values shown in bold text also exceed both upper and lower Hazeltine Creek Historic 95th Percentile values.

Table E.7: Raw selectively extracted (Tessier extraction) metals data for sediment from Hazeltine Creek, Mount Polley Mine, 2014. Data are based on < 2mm fraction of sediment [1].

Analyte	Units	BC WSQG [2]		CSR [3]		Historic Hazeltine Creek 95th Percentile [4] (total metal concentration)		Upper Hazeltine Creek (ST16)

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < highest MDL if all the data used in their calculation were < MDL. Medians are reported as the < MDL value closest to calculated median if all data are < MDL (relevant for sample sizes of 4).

[2] British Columbia Water Quality Guidelines (BCMOE 2015a, 2015b); W=Working guideline; A=Approved guideline. See Appendix Table E.10 for derivation of hardness-based guidelines.

[3] Insufficient porewater volume to analyse total or dissolved metals in sample ST16-04 or to analyse total metal concentrations in samples ST16-S2, ST16-S3 or ST16-S5.

[4] Displayed guideline value is for dissolved cadium.

[5] Applies to chromium as Cr (IV); guideline for Cr(III) is 0.0089 mg/L.

[6] Total nickel guideline value is for acute exposure, as described in guideline document (CCREM 1987)

(orange shading) Value is > one or all guidelines (values < MDL excluded from comparison).

Table E.9: Porewater metals data for sediment from Hazeltine Creek sampling areas, Mount Polley Mine, 2014 [1].

Analyte	Units	Leachable Metals [a] (All waterbodies)	Pore water (Hazeltine Creek)
Hardness	(mg/L)	137	279

[a] Hardness of leachable metals was calculated from reported calcium and magnesium concentrations using the equation Hardness (mg/L $CaCO_3$) = 2.497*[Ca (mg/L)] + 4.118*[Mg (mg/L)]

B) Condition-Specific Guidelines

Analyte	Jurisdiction	Approved or Working	Chronic or Acute	Condition or Equation	Applicable Guideline: Leacheable Metals (All water bodies)		Applicable Guideline: Porewater (Hazeltine Creek)	
					ug/L	mg/L	ug/L	mg/L
Cadmium (Dissolved)	BC	Approved	Long - Term	e^(0.736*(ln(hardness))-4.943)	0.267	0.000267	0.450	0.000450
			Short - Term	e^(1.03*(ln(hardness))-5.274)	0.813	0.0008	1.69	0.0017
Copper	BC	Approved	30-day average	0.04*hardness	5.48	0.005	11.2	0.011
			Maximum	0.094*hardness + 2	14.9	0.0149	28.2	0.028
Lead	BC	Approved	30-day average	3.31+ e^(1.273(ln(hardness))-4.704)	8.1	0.0081	15.1	0.0151
			Maximum	e^(1.273(ln(hardness))-1.46)	122	0.122	301	0.301
Manganese	BC	Approved	30-day average	0.0044*hardness - 0.605	1,208	1.21	1,833	1.83
			Maximum	0.01102*hardness + 0.54	2,050	2.05	3,615	3.61
Nickel [b]	BC	Working	Maximum	when hardness ≤ 60: 25 ug/L	-	-	-	-
				when hardness 60 - 180 mg/L; e^(0.76(ln(hardness))+1.06)	121	0.121	-	-
				when hardness ≥ 180 mg/L; 150 ug/L	-	-	150	0.150
Mercury [c]	BC	Approved	30-day average	when MeHg = 0.5% of THg; 0.02 ug/L	0.02	0.00002	0.02	0.00002
				when MeHg = 1.0% of THg; 0.01 ug/L	-	-	-	-
				when MeHg = 8.0% of THg; 0.00125 ug/L	-	-	-	-
Silver	BC	Approved	Condition:	H < 100 mg/L / H > 100 mg/L				
			30-day average	0.05 / 1.5	1.50	0.00150	1.5	0.0015
			Maximum	0.1 / 3	3.0	0.0030	3.0	0.0030
Zinc	BC	Approved	30-day average	when hardness <90: 7.5 ug/L				
				when hardness >90; 7.5 + 0.75 * (hardness-90)	42.8	0.043	149	0.149
			Maximum	when hardness <90: 33 ug/L				
				when hardness >90; 33 + 0.75 * (hardness-90)	68.3	0.0683	175	0.175

[b] Total nickel guideline value is for acute exposure, as described in guideline document (CCREM 1987)

[c] Highest mercury guideline value used for application to mercury; MeHg = 0.5% of THg

[1] Reported TOC, TN, pH and moisture data are based on bulk sediment. Data < method detection limit (MDL) were used at the MDL for calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996).

[4] The 5th percentile is reported for pH.

[5] Historic sediment metal concentrations are based predominantly on bulk sediment samples.

[6] Samples were collected using a sediment corer.

[7] Samples were collected using a petite ponar.

(blue shading) Value is > TEL. Values shown in bold text also exceed both Reference values.

(orange shading) Value is > PEL. Values shown in bold text also exceed both Reference values.

Table E.17: Raw sediment quality data for mid-depth stations in Polley Lake, Mount Polley Mine, 2014. Data are based on the <63µm fraction of sediment [1].

[1] Means are reported as < MDL if all the data used in their calculation were < MDL.

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996).

[4] The 5th percentile is reported for pH.

[5] Historic sediment metal concentrations are based predominantly on bulk sediment samples.

[6] Samples were collected using a sediment corer.

[7] Samples were collected using a petite ponar.

(blue) Value is > TEL. Values shown in bold text also exceed both Reference values.

(orange) Value is > PEL. Values shown in bold text also exceed both Reference values.

Table E.18: Raw sediment quality data for deep lake stations P1 and P2 in Polley Lake, Mount Polley Mine, 2014. Data are based on the <63µm fraction of sediment[1].

[1] Reported TOC, TN, pH, and moisture data are based on bulk sediment. Data < method detection limit (MDL) were used at the MDL for calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.
[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.
[3] Contaminated Sites Regulation (Government of British Columbia 1996).
[4] Samples were collected using a sediment corer.
[5] Samples were collected using a petite ponar.
[6] The 5th percentile is reported for pH.

(blue)	Value is > TEL. Values shown in bold text also exceed Historic 95th Percentile value.
(orange)	Value is > PEL. Values shown in bold text also exceed Historic 95th Percentile value.

[1] Reported TOC, TN, pH and moisture data are based on bulk sediment. Data < method detection limit (MDL) were used at the MDL for calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996).

[4] Samples were collected using a sediment corer.

[5] Samples were collected using a petite ponar.

[6] The 5th percentile is reported for pH.

(blue) Value is > TEL. Values shown in bold text also exceed Historic 95th Percentile value.

(orange) Value is > PEL. Values shown in bold text also exceed Historic 95th Percentile value.

Table E.21: Raw sediment quality data for mid-depth areas of Bootjack Lake, Mount Polley Mine, 2014. Data are based on the <63µm fraction of sediment [1].

[1] Data < method detection limit (MDL) were used at the MDL for calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996).

[4] Samples were collected using a sediment corer.

[5] Samples were collected using a petite ponar.

[6] The 5th percentile is reported for pH.

(blue) Value is > TEL. Values shown in bold text also exceed Historic 95th Percentile value.

(orange) Value is > PEL. Values shown in bold text also exceed Historic 95th Percentile value.

Table E.23: PCA results displaying; eigen value, percent variance explained, Monte Carlo randomization p-values of axis significance, and station scores for < 2mm sediment from Polley and Bootjack mid-depth sampling stations, Mount Polley Mine, 2014. [1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.

[2] Samples were collected using a sediment corer.

[3] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[4] Contaminated Sites Regulation (Government of British Columbia 1996)

Value is > TEL. Values shown in bold text also exceed Reference 95th percentile value.

Value is > PEL. Values shown in bold text also exceed Reference 95th percentile value.

Table E.35: Raw selectively extracted (Tessier extraction) metals data for sediment from Polley Lake mid-depth sampling areas, Mount Polley Mine, 2014. Data are based on < 2mm fraction of sediment [1,2].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.

[2] Samples were collected using a sediment corer.

[3] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[4] Contaminated Sites Regulation (Government of British Columbia 1996)

(blue) Value is > TEL. Values shown in bold text also exceed Reference 95th percentile value.

(orange) Value is > PEL. Values shown in bold text also exceed Reference 95th percentile value.

Table E.35: Raw selectively extracted (Tessier extraction) metals data for sediment from Polley Lake mid-depth sampling areas, Mount Polley Mine, 2014. Data are based on < 2mm fraction of sediment [1,2].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.

[2] Samples were collected using a sediment corer.

[3] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[4] Contaminated Sites Regulation (Government of British Columbia 1996)

(blue) Value is > TEL. Values shown in bold text also exceed Reference 95th percentile value.

(orange) Value is > PEL. Values shown in bold text also exceed Reference 95th percentile value.

Table E.36: Raw selectively extracted (Tessier extraction) metals data for sediment from Polley Lake deep sampling areas, Mount Polley Mine, 2014. Data are based on < 2mm fraction of sediment [1,2].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.

[2] Samples were collected using a sediment corer.

[3] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[4] Contaminated Sites Regulation (Government of British Columbia 1996)

[5] Samples were collected using a petite ponar.

(blue) Value is > TEL. Values shown in bold text also exceed Reference 95th percentile value.

(orange) Value is > PEL. Values shown in bold text also exceed Reference 95th percentile value.

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Summary statistics are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.

[2] Samples were collected using a sediment corer.

[3] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[4] Contaminated Sites Regulation (Government of British Columbia 1996)

(blue)	Value is > TEL.
(orange)	Value is > PEL.

Table E.38: Raw selectively extracted (Tessier extraction) metals data for sediment from Bootjack Lake deep sampling areas, Mount Polley Mine, 2014. Data are based on < 2mm fraction of sediment[1,2].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.

[2] British Columbia Water Quality Guidelines (BCMOE 2015a, 2015b); W=Working guideline; A=Approved guideline. See Appendix Table E.10 for derivation of hardness-based guidelines.

[3] Hazardous Waste Regulation (Government of British Columbia 1988)

[4] Samples were collected using a sediment corer.

[5] Samples were collected using a petite ponar.

[6] Applies to chromium as Cr (IV); guideline for Cr(III) is 0.0089 mg/L.

[6] Total nickel guideline value is for acute exposure, as described in guideline document (CCREM 1987)

[orange box] Value is > either guideline (values < MDL excluded). Values shown in bold text also exceed Reference 95th percentile value.

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.

[2] British Columbia Water Quality Guidelines (BCMOE 2015a, 2015b); W=Working guideline; A=Approved guideline. See Appendix Table E.10 for derivation of hardness-based guidelines.

[3] Hazardous Waste Regulation (Government of British Columbia 1988)

[4] Samples were collected using a sediment corer.

[5] Samples were collected using a petite ponar.

[6] Applies to chromium as Cr (IV); guideline for Cr(III) is 0.0089 mg/L.

[6] Total nickel guideline value is for acute exposure, as described in guideline document (CCREM 1987)

(orange box) Value is > either guideline (values < MDL excluded). Values shown in bold text also exceed Reference 95th percentile value.

Table E.40: Raw leachable metals data for sediment from Polley Lake deep sampling areas, Mount Polley Mine, 2014. Data are based on bulk sediment[1].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.

[2] British Columbia Water Quality Guidelines (BCMOE 2015a, 2015b); W=Working guideline; A=Approved guideline. See Appendix Table E.10 for derivation of hardness-based guidelines.

[3] Hazardous Waste Regulation (Government of British Columbia 1988)

[4] Samples were collected using a sediment corer.

[5] Samples were collected using a petite ponar.

[6] Applies to chromium as Cr (IV); guideline for Cr(III) is 0.0089 mg/L.

[7] Total nickel guideline value is for acute exposure, as described in guideline document (CCREM 1987)

[orange box] Value is > either guideline (values < MDL excluded). Values shown in bold text also exceed Reference 95th percentile value.

Table E.41: Raw leachable metals data for sediment from Bootjack Lake mid-depth sampling areas, Mount Polley Mine, 2014. Data are based on bulk sediment [1].

[1] Data < method detection limit (MDL) were used at the MDL for calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.

[2] British Columbia Water Quality Guidelines (BCMOE 2015a, 2015b); W=Working guideline; A=Approved guideline. See Appendix Table E.10 for derivation of hardness-based guidelines.

[3] Hazardous Waste Regulation (Government of British Columbia 1988)

[4] Samples were collected using a petite ponar.

[5] Applies to chromium as Cr (IV); guideline for Cr(III) is 0.0089 mg/L.

[6] Total nickel guideline value is for acute exposure, as described in guideline document (CCREM 1987)

(orange box) Value is > one or all guidelines (values < MDL excluded).

[1] Reported TOC, TN, pH, and moisture data are based on bulk sediment. Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996)

[4] Reference 95th percentile was calculated using displayed metals data for the < 2mm sediment fraction, and using displayed TOC, pH, TN, particle size and moisture data. The 5th percentile is reported for pH.

[5] Summary statistics (95th percentile, mean, t*SE, and maximum) for reference area LRef2 are based only on data from replicates QUL-52-01 to QUL-52-03 due to high sand content in replicates QUL-52-04 and QUL-52-05 (> 90%).

(blue) Value is > TEL. Values shown in bold text also exceed both Reference 95th Percentile values.

(orange) Value is > PEL. Values shown in bold text also exceed both Reference 95th Percentile values.

Table E.45: Raw sediment quality data for Quesnel Lake littoral sampling areas, Mount Polley Mine, 2014. Metals data are based on the < 2mm fraction of sediment [1].

[1] Reported TOC, TN, pH, and moisture data are based on bulk sediment. Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996)

[4] Reference 95th percentile was calculated using displayed metals data for the < 2mm sediment fraction, and using displayed TOC, pH, TN, particle size and moisture data. The 5th percentile is reported for pH.

[5] Summary statistics (95th percentile, mean, t*SE, and maximum) for reference area LRef2 are based only on data from replicates QUL-52-01 to QUL-52-03 due to high sand content in replicates QUL-52-04 and QUL-52-05 (> 90%).

(blue) Value is > TEL. Values shown in bold text also exceed both Reference 95th Percentile values.

(orange) Value is > PEL. Values shown in bold text also exceed both Reference 95th Percentile values.

Table E.45: Raw sediment quality data for Quesnel Lake littoral sampling areas, Mount Polley Mine, 2014. Metals data are based on the < 2mm fraction of sediment [1].

[1] Reported TOC, TN, pH, and moisture data are based on bulk sediment. Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996)

[4] Reference 95th percentile was calculated using displayed metals data for the < 2mm sediment fraction, and using displayed TOC, pH, TN, particle size and moisture data. The 5th percentile is reported for pH.

[5] Summary statistics (95th percentile, mean, t*SE, and maximum) for reference area LRef2 are based only on data from replicates QUL-52-01 to QUL-52-03 due to high sand content in replicates QUL-52-04 and QUL-52-05 (> 90%).

(Blue) Values is > TEL. Values shown in bold text also exceed both Reference 95th Percentile values.

(Orange) Value is > PEL. Values shown in bold text also exceed both Reference 95th Percentile values.

Table E.46: Raw sediment quality data for Quesnel Lake littoral sampling areas, Mount Polley Mine, 2014. Data are based on the < 63µm fraction of sediment [1].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.
[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.
[3] Contaminated Sites Regulation (Government of British Columbia 1996)
[4] Reference 95th percentile was calculated using displayed data for the <63µm sediment fraction. The 5th percentile is reported for pH.

(blue) Values is > TEL. Values shown in bold text also exceed both Reference 95th Percentile values.
(orange) Value is > PEL. Values shown in bold text also exceed both Reference 95th Percentile values.

Table E.46: Raw sediment quality data for Quesnel Lake littoral sampling areas, Mount Polley Mine, 2014. Data are based on the < 63µm fraction of sediment [1].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.
[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.
[3] Contaminated Sites Regulation (Government of British Columbia 1996)
[4] Reference 95th percentile was calculated using displayed data for the <63µm sediment fraction. The 5th percentile is reported for pH.

(blue) Values is > TEL. Values shown in bold text also exceed both Reference 95th Percentile values.
(orange) Value is > PEL. Values shown in bold text also exceed both Reference 95th Percentile values.

Table E.46: Raw sediment quality data for Quesnel Lake littoral sampling areas, Mount Polley Mine, 2014. Data are based on the < 63µm fraction of sediment [1].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.
Summary statistics were only calculated for sampling areas with replicate samples (LRef1, LNF1,and LNF2) but not for single composite samples (LRef2, LFF, and LFFF).

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996)

[4] Displayed reference values are the 95th percentiles of data from reference area LRef1 and are the single values available for reference area LRef2.

(Blue) Value is > TEL. Values shown in bold text also exceed both Reference 95th Percentile values.

(Orange) Value is > PEL. Values shown in bold text also exceed both Reference 95th Percentile values.

Table E.51: Raw selectively extracted (Tessier extraction) metals data for sediment from Quesnel Lake littoral sampling areas, Mount Polley Mine, 2014. Data are based on < 2mm fraction of sediment [1].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.
Summary statistics were only calculated for sampling areas with replicate samples (LRef1, LNF1,and LNF2) but not for single composite samples (LRef2, LFF, and LFFF).

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996)

[4] Displayed reference values are the 95th percentiles of data from reference area LRef1 and are the single values available for reference area LRef2.

(blue) Value is > TEL. Values shown in bold text also exceed both Reference 95th Percentile values.

(orange) Value is > PEL. Values shown in bold text also exceed both Reference 95th Percentile values.

Table E.51: Raw selectively extracted (Tessier extraction) metals data for sediment from Quesnel Lake littoral sampling areas, Mount Polley Mine, 2014. Data are based on < 2mm fraction of sediment [1].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.
Summary statistics were only calculated for sampling areas with replicate samples (LRef1, LNF1,and LNF2) but not for single composite samples (LRef2, LFF, and LFFF).

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996)

[4] Displayed reference values are the 95th percentiles of data from reference area LRef1 and are the single values available for reference area LRef2.

(blue) Value is > TEL. Values shown in bold text also exceed both Reference 95th Percentile values.

(orange) Value is > PEL. Values shown in bold text also exceed both Reference 95th Percentile values.

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.
Summary statistics were only calculated for sampling areas with replicate samples (LRef1, LNF1,and LNF2) but not for single composite samples (LRef2, LFF, and LFFF).

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996)

[4] Displayed reference values are the 95th percentiles of data from reference area LRef1 and are the single values available for reference area LRef2.

Value is > TEL. Values shown in bold text also exceed both Reference 95th Percentile values.

Value is > PEL. Values shown in bold text also exceed both Reference 95th Percentile values.

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.
Summary statistics were only calculated for sampling areas with replicate samples (LRef1, LNF1,and LNF2) but not for single composite samples (LRef2, LFF, and LFFF).

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996)

[4] Displayed reference values are the 95th percentiles of data from reference area LRef1 and are the single values available for reference area LRef2.

(blue) Value is > TEL. Values shown in bold text also exceed both Reference 95th Percentile values.

(orange) Value is > PEL. Values shown in bold text also exceed both Reference 95th Percentile values.

Table E.51: Raw selectively extracted (Tessier extraction) metals data for sediment from Quesnel Lake littoral sampling areas, Mount Polley Mine, 2014. Data are based on < 2mm fraction of sediment [1].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL. Summary statistics were only calculated for sampling areas with replicate samples (LRef1, LNF1,and LNF2) but not for single composite samples (LRef2, LFF, and LFFF).

[2] British Columbia Water Quality Guidelines (BCMOE 2015a, 2015b); W=Working guideline; A=Approved guideline. See Appendix Table E.10 for derivation of hardness-based guidelines.

[3] Hazardous Waste Regulation (Government of British Columbia 1988)

[4] Displayed reference values are the 95th percentiles of data from reference area LRef1, and are the single values available for reference area LRef2.

[5] Applies to chromium as Cr (IV); guideline for Cr(III) is 0.0089 mg/L.

[6] Total nickel guideline value is for acute exposure, as described in guideline document (CCREM 1987)

(orange) Value is > either guideline (values < MDL excluded). Values shown in bold text also exceed both Reference Values.

Table E.52: Raw leachable metals data for sediment from Quesnel Lake littoral sampling areas, Mount Polley Mine, 2014. Data are based on bulk sediment [1].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL. Summary statistics were only calculated for sampling areas with replicate samples (LRef1, LNF1,and LNF2) but not for single composite samples (LRef2, LFF, and LFFF).

[2] British Columbia Water Quality Guidelines (BCMOE 2015a, 2015b); W=Working guideline; A=Approved guideline. See Appendix Table E.10 for derivation of hardness-based guidelines.

[3] Hazardous Waste Regulation (Government of British Columbia 1988)

[4] Displayed reference values are the 95th percentiles of data from reference area LRef1, and are the single values available for reference area LRef2.

[5] Applies to chromium as Cr (IV); guideline for Cr(III) is 0.0089 mg/L.

[6] Total nickel guideline value is for acute exposure, as described in guideline document (CCREM 1987)

(orange box) Value is > either guideline (values < MDL excluded). Values shown in bold text also exceed both Reference Values.

Table E.53: Raw acid base accounting, sulphur, and carbon content data for sediment from littoral sampling areas in Quesnel Lake, Mount Polley, 2014 [1].

[1] Reported TOC, TN, pH, and moisture data are based on bulk sediment. Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996)

[4] Reference 95th percentile was calculated using displayed metals data for the < 2mm sediment fraction, and using displayed TOC, pH, TN, particle size and moisture data. The 5th percentile is reported for pH

(blue) Value is > TEL. Values shown in bold text also exceed Reference 95th Percentile values.

(orange) Value is > PEL. Values shown in bold text also exceed Reference 95th Percentile values.

Table E.54: Raw sediment quality data for Quesnel Lake profundal sampling areas, Mount Polley Mine, 2014. Metals data are based on the < 2mm fraction of sediment [1].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.
[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.
[3] Contaminated Sites Regulation (Government of British Columbia 1996)
[4] Reference 95th percentile was calculated using displayed data for the <63µm sediment fraction. The 5th percentile is reported for pH.

(blue) Value is > TEL. Values shown in bold text also exceed Reference 95th Percentile values.
(orange) Value is > PEL. Values shown in bold text also exceed Reference 95th Percentile values.

Table E.55: Raw sediment quality data for Quesnel Lake profundal sampling areas, Mount Polley Mine, 2014. Metals data are based on the < 63µm fraction of sediment [1].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < MDL if all the data used in their calculation were < MDL.
[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.
[3] Contaminated Sites Regulation (Government of British Columbia 1996)
[4] Reference 95th percentile was calculated using displayed data for the <63µm sediment fraction. The 5th percentile is reported for pH.

(blue) Value is > TEL. Values shown in bold text also exceed Reference 95th Percentile values.
(orange) Value is > PEL. Values shown in bold text also exceed Reference 95th Percentile values.

Table E.55: Raw sediment quality data for Quesnel Lake profundal sampling areas, Mount Polley Mine, 2014. Metals data are based on the < 63µm fraction of sediment [1].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Summary statistics are reported as < MDL if all the data used in their calculation were < MDL.
[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.
[3] Contaminated Sites Regulation (Government of British Columbia 1996)
[4] Reference 95th percentile was calculated using displayed data for the <63µm sediment fraction. The 5th percentile is reported for pH.

(blue) Value is > TEL. Values shown in bold text also exceed Reference 95th Percentile values.
(orange) Value is > PEL. Values shown in bold text also exceed Reference 95th Percentile values.

Table E.55: Raw sediment quality data for Quesnel Lake profundal sampling areas, Mount Polley Mine, 2014. Metals data are based on the < 63µm fraction of sediment [1].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.
Summary statistics were only calculated for sampling areas with replicate samples (PRef1, PNF,and PFF1) but not for single composite samples (PRef2, PFF2, and PFFF).
[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.
[3] Contaminated Sites Regulation (Government of British Columbia 1996)
[4] Displayed reference values are the 95th percentiles of data from reference area PRef1 and are the single values available for reference area PRef2.

(blue)	Value is > TEL. Values shown in bold text also exceed Reference values.
(orange)	Value is > PEL. Values shown in bold text also exceed Reference values.

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.
Summary statistics were only calculated for sampling areas with replicate samples (PRef1, PNF,and PFF1) but not for single composite samples (PRef2, PFF2, and PFFF).
[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.
[3] Contaminated Sites Regulation (Government of British Columbia 1996)
[4] Displayed reference values are the 95th percentiles of data from reference area PRef1 and are the single values available for reference area PRef2.

(blue)	Value is > TEL. Values shown in bold text also exceed Reference values.
(orange)	Value is > PEL. Values shown in bold text also exceed Reference values.

Table E.60: Raw selectively extracted (Tessier extraction) metals data for sediment from Quesnel Lake profundal sampling areas, Mount Polley Mine, 2014. Data are based on < 2mm fraction of sediment [1].

Sample ID	Units	BC SQGs [2]		CSR [3]		Reference Value [4]		Exposed												
								PFF1 (QULP-2)												PFFF (QULP-3)
								QULP-2-01	QULP-2-02	QULP-2-03	QULP-2-04	QULP-2-05	Mean	Median	Minimum	Maximum	Standard Deviation	Standard Error	t*SE	Composite
Date Sampled		**TEL**	**PEL**	**Sensitive**	**Typical**	**PRef1**	**PRef2**	19-Sep-14	19-Sep-14	19-Sep-14	20-Sep-14	20-Sep-14								18-Oct-14

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.
Summary statistics were only calculated for sampling areas with replicate samples (PRef1, PNF,and PFF1) but not for single composite samples (PRef2, PFF2, and PFFF).
[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.
[3] Contaminated Sites Regulation (Government of British Columbia 1996)
[4] Displayed reference values are the 95th percentiles of data from reference area PRef1 and are the single values available for reference area PRef2.
Value is > TEL. Values shown in bold text also exceed Reference values.
Value is > PEL. Values shown in bold text also exceed Reference values.

Table E.60: Raw selectively extracted (Tessier extraction) metals data for sediment from Quesnel Lake profundal sampling areas, Mount Polley Mine, 2014. Data are based on < 2mm fraction of sediment [1].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.
Summary statistics were only calculated for sampling areas with replicate samples (PRef1, PNF,and PFF1) but not for single composite samples (PRef2, PFF2, and PFFF).

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996)

[4] Displayed reference values are the 95th percentiles of data from reference area PRef1 and are the single values available for reference area PRef2.

[blue] Value is > TEL. Values shown in bold text also exceed Reference values.

[orange] Value is > PEL. Values shown in bold text also exceed Reference values.

Table E.60: Raw selectively extracted (Tessier extraction) metals data for sediment from Quesnel Lake profundal sampling areas, Mount Polley Mine, 2014. Data are based on < 2mm fraction of sediment [1].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.
Summary statistics were only calculated for sampling areas with replicate samples (PRef1, PNF,and PFF1) but not for single composite samples (PRef2, PFF2, and PFFF).

[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.

[3] Contaminated Sites Regulation (Government of British Columbia 1996)

[4] Displayed reference values are the 95th percentiles of data from reference area PRef1 and are the single values available for reference area PRef2.

(blue) Value is > TEL. Values shown in bold text also exceed Reference values.

(orange) Value is > PEL. Values shown in bold text also exceed Reference values.

Table E.60: Raw selectively extracted (Tessier extraction) metals data for sediment from Quesnel Lake profundal sampling areas, Mount Polley Mine, 2014. Data are based on < 2mm fraction of sediment [1].

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.
Summary statistics were only calculated for sampling areas with replicate samples (PRef1, PNF,and PFF1) but not for single composite samples (PRef2, PFF2, and PFFF).
[2] British Columbia Working Sediment Quality Guidelines (BCMOE 2015a, 2015b); TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level.
[3] Contaminated Sites Regulation (Government of British Columbia 1996)
[4] Displayed reference values are the 95th percentiles of data from reference area PRef1 and are the single values available for reference area PRef2.

(blue)	Value is > TEL. Values shown in bold text also exceed Reference values.
(orange)	Value is > PEL. Values shown in bold text also exceed Reference values.

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL.
Summary statistics were only calculated for sampling areas with replicate samples (PRef1, PNF,and PFF1) but not for single composite samples (PRef2, PFF2, and PFFF).

[2] British Columbia Water Quality Guidelines (BCMOE 2015a, 2015b); W=Working guideline; A=Approved guideline. See Appendix Table E.10 for derivation of hardness-based guidelines.

[3] Hazardous Waste Regulation (Government of British Columbia 1988)

[4] Displayed reference values are the 95th percentiles of data from reference area PRef1, and are the single values available for reference area PRef2.

[5] Applies to chromium as Cr (IV); guideline for Cr(III) is 0.0089 mg/L.

[6] Total nickel guideline value is for acute exposure, as described in guideline document (CCREM 1987)

(orange shading) Value is > either guideline (values < MDL excluded). Values shown in bold text also exceed Reference values.

[1] Data < method detection limit (< MDL) were used at the MDL for the calculation of summary statistics. Means are reported as < the highest displayed MDL if all the data used in their calculation were < MDL. Summary statistics were only calculated for sampling areas with replicate samples (PRef1, PNF,and PFF1) but not for single composite samples (PRef2, PFF2, and PFFF).

[2] British Columbia Water Quality Guidelines (BCMOE 2015a, 2015b); W=Working guideline; A=Approved guideline. See Appendix Table E.10 for derivation of hardness-based guidelines.

[3] Hazardous Waste Regulation (Government of British Columbia 1988)

[4] Displayed reference values are the 95th percentiles of data from reference area PRef1, and are the single values available for reference area PRef2.

[5] Applies to chromium as Cr (IV); guideline for Cr(III) is 0.0089 mg/L.

[6] Total nickel guideline value is for acute exposure, as described in guideline document (CCREM 1987)

(orange shading) Value is > either guideline (values < MDL excluded). Values shown in bold text also exceed Reference values.

Table E.61: Raw leachable metals data for sediment from Quesnel Lake profundal sampling areas, Mount Polley Mine, 2014. Data are based on bulk sediment [1].

Figure E.1: Spearman's correlation relationships between concentrations of metals in sediment (in < 2mm fraction) and % fines (silt and clay) in sediment from Hazeltine Creek sampling areas, Mount Polley Mine, 2014.

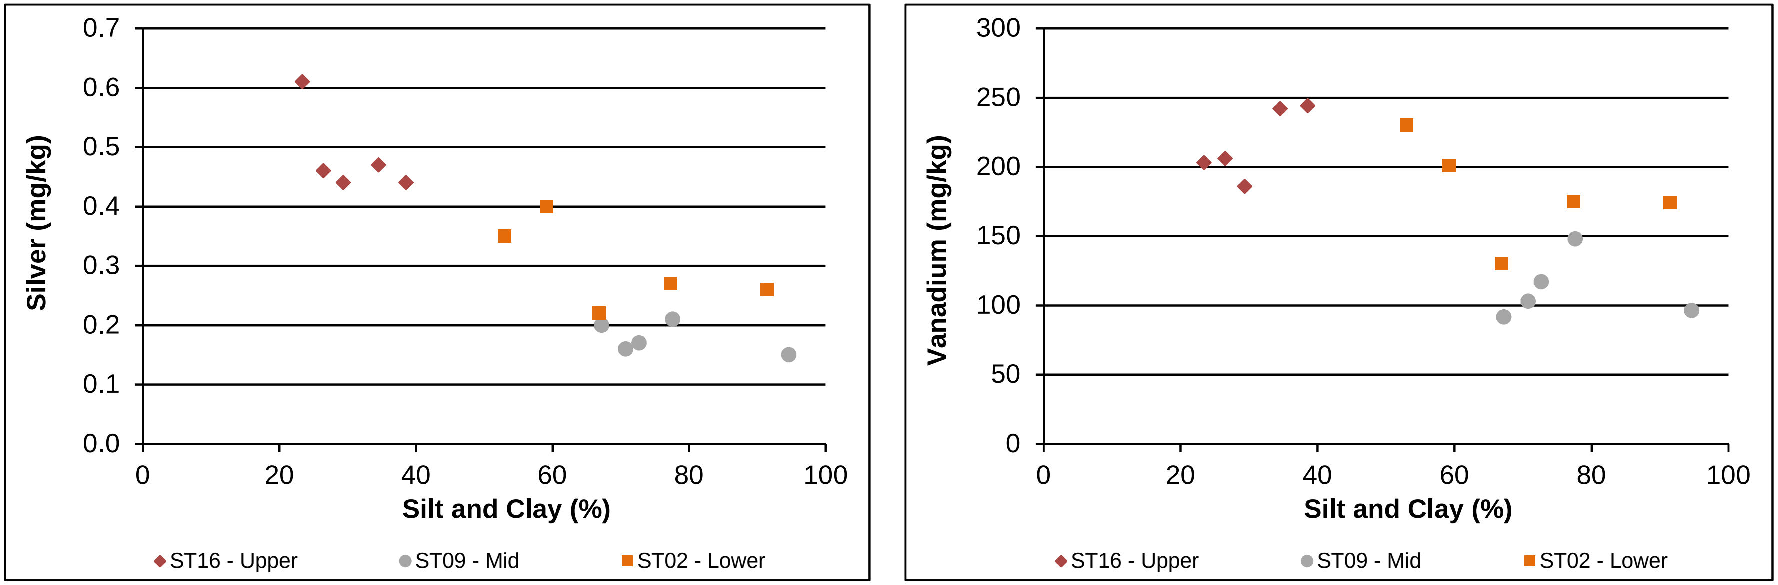

Figure E.1: Spearman's correlation relationships between concentrations of metals in sediment (in < 2mm fraction) and % fines (silt and clay) in sediment from Hazeltine Creek sampling areas, Mount Polley Mine, 2014.

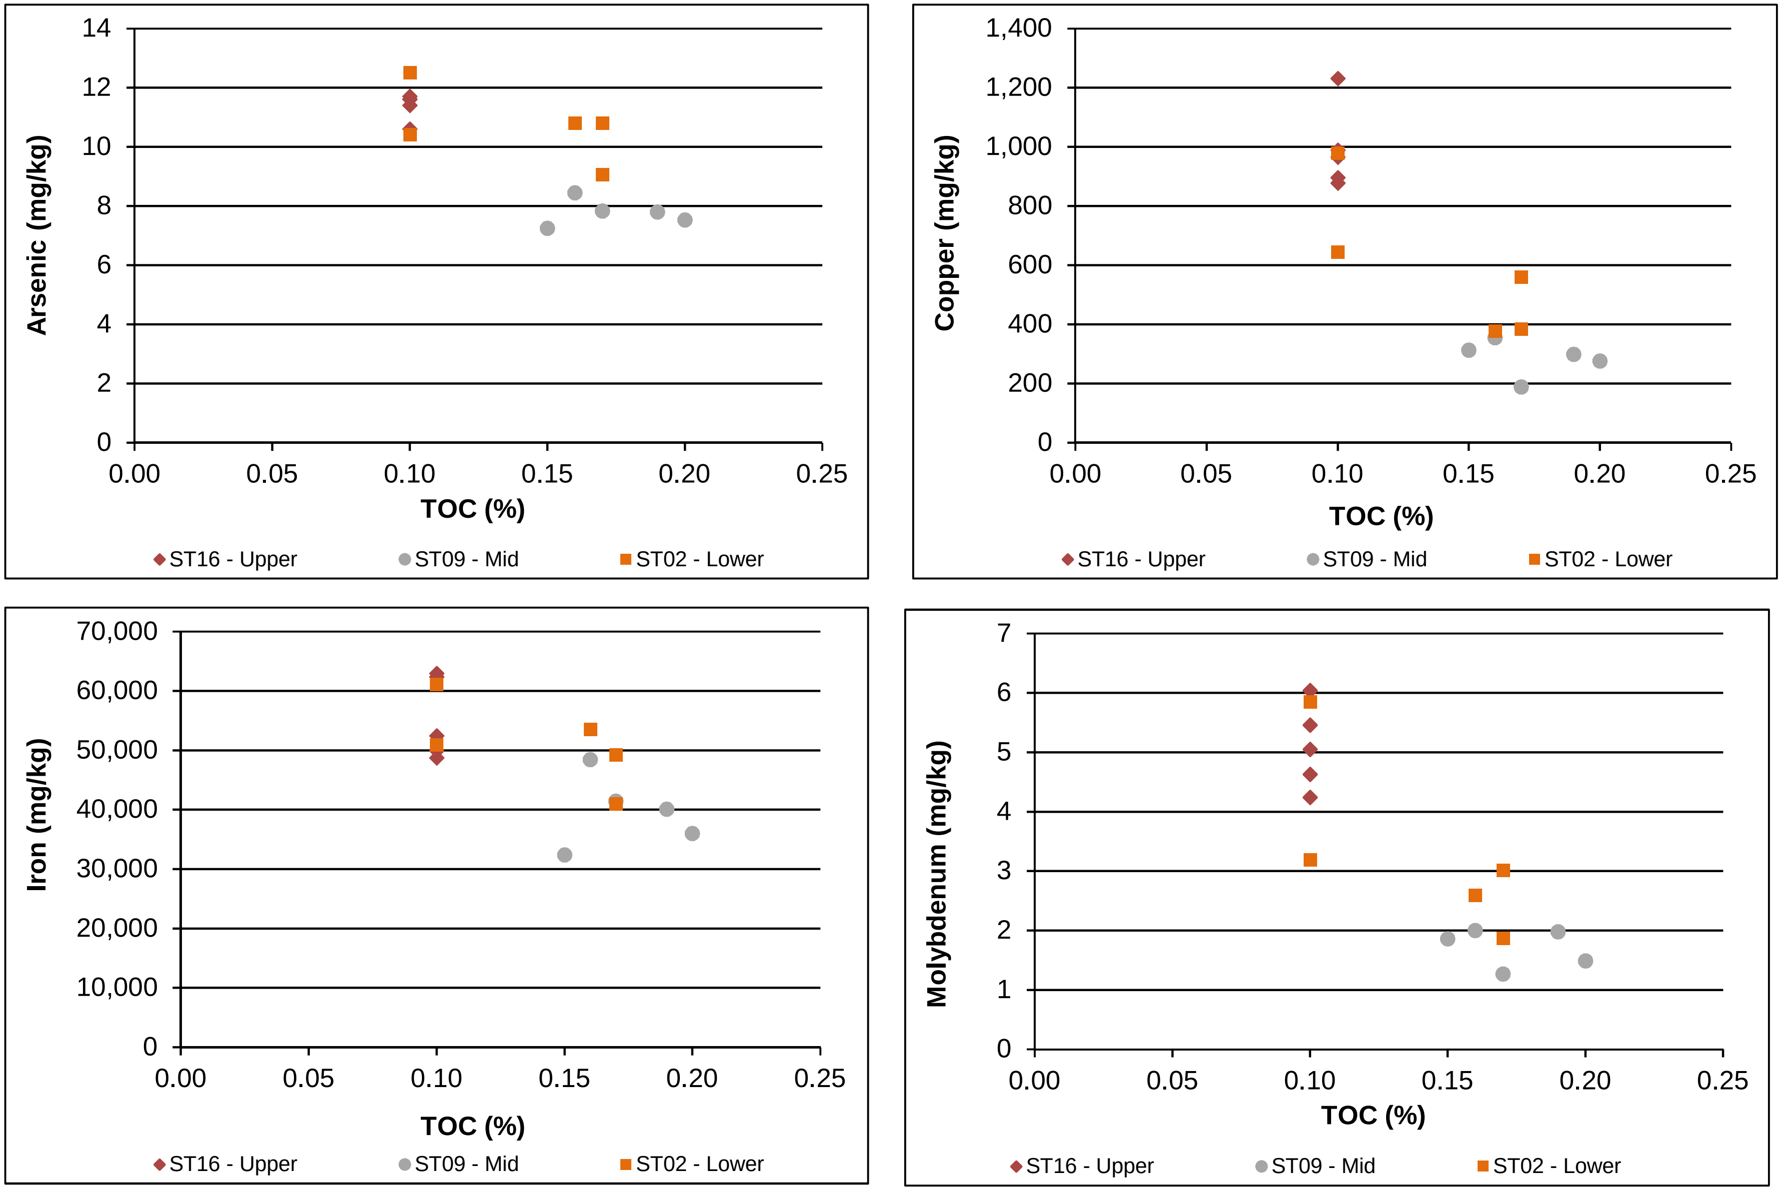

Figure E.2: Spearman's correlation relationships between concentrations of metals in sediment (in < 2mm fraction) and total organic carbon (%) in sediment from Hazeltine Creek sampling areas , Mount Polley Mine, 2014.

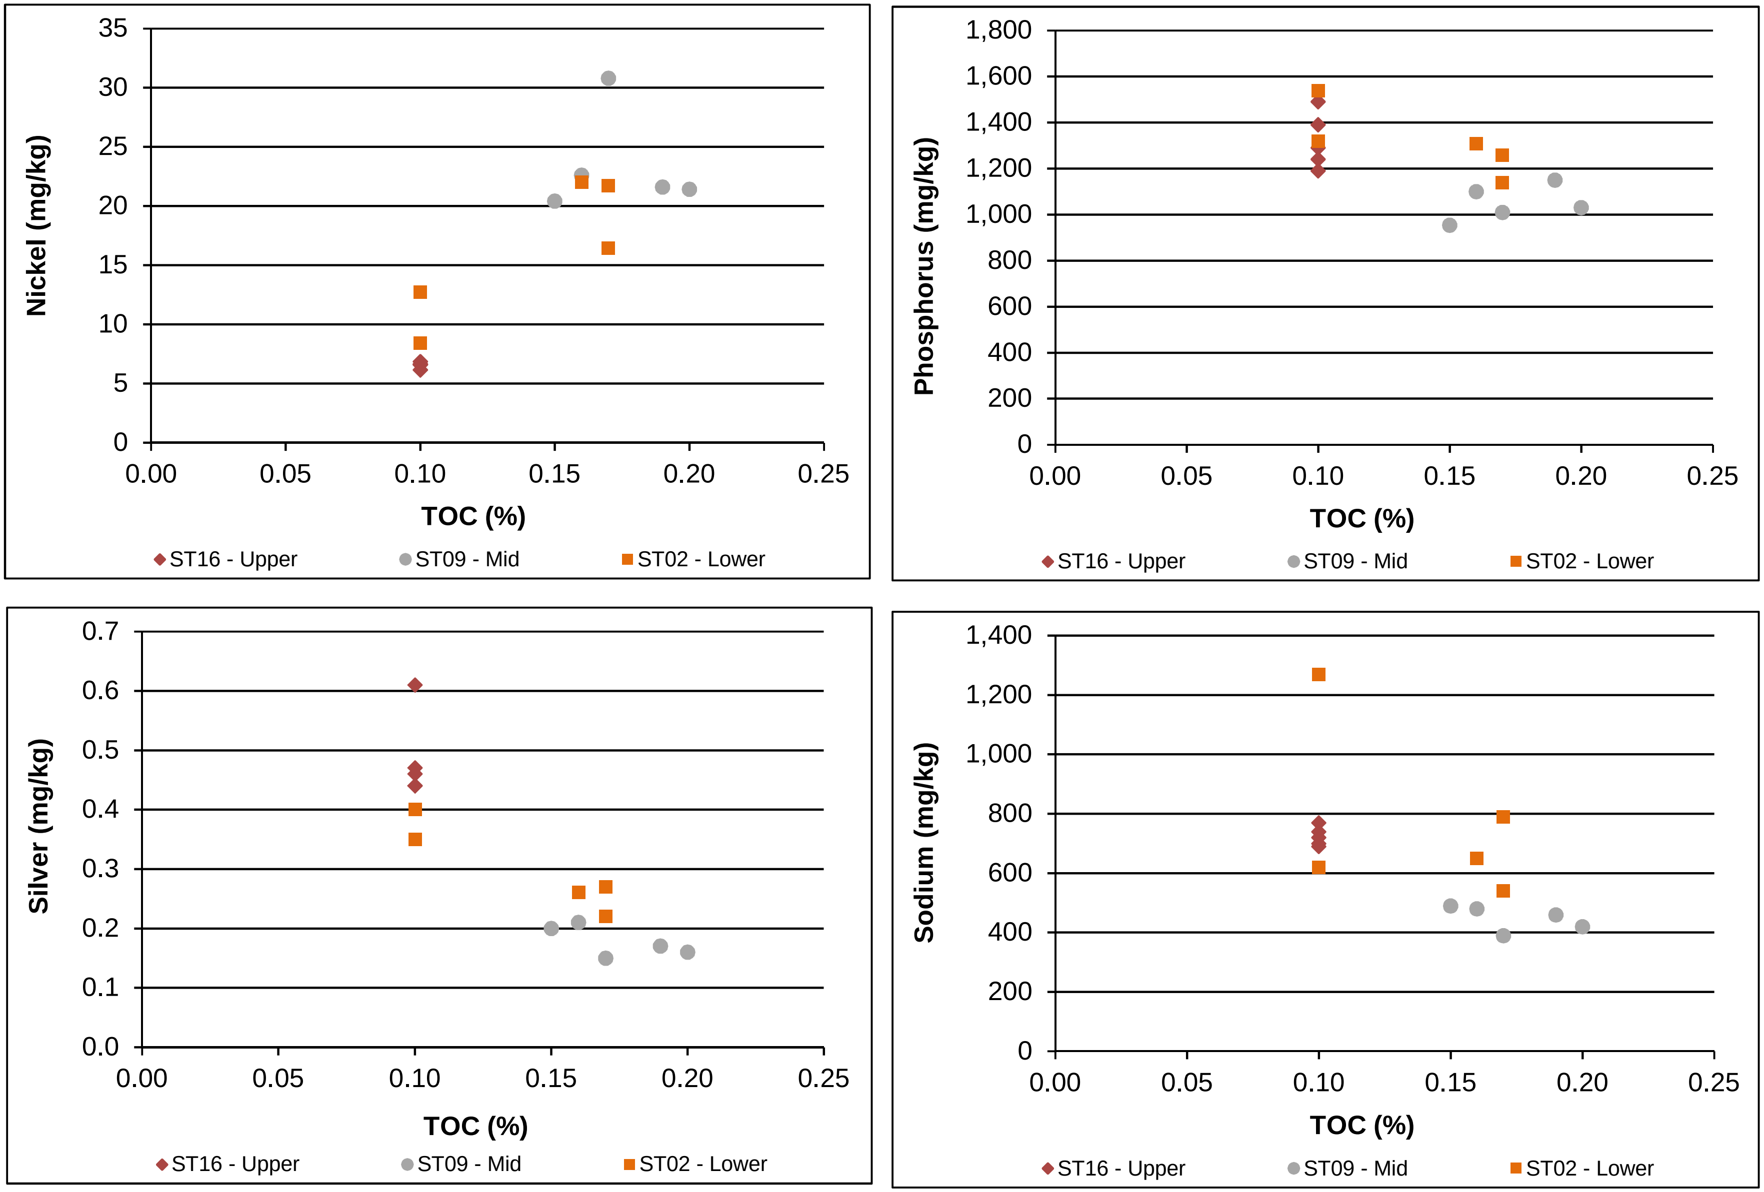

Figure E.2: Spearman's correlation relationships between concentrations of metals in sediment (in < 2mm fraction) and total organic carbon (%) in sediment from Hazeltine Creek sampling areas , Mount Polley Mine, 2014.

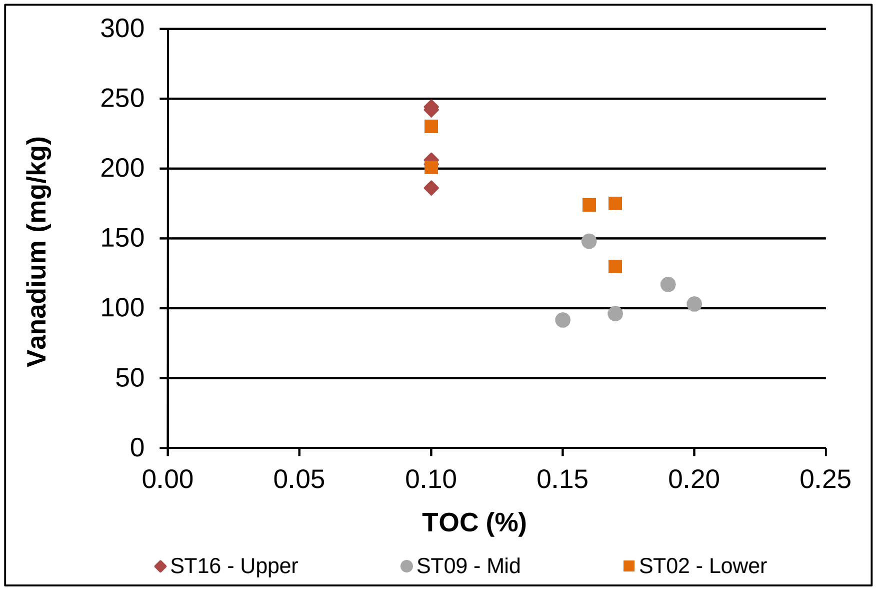

Figure E.2: Spearman's correlation relationships between concentrations of metals in sediment (in < 2mm fraction) and total organic carbon (%) in sediment from Hazeltine Creek sampling areas , Mount Polley Mine, 2014.

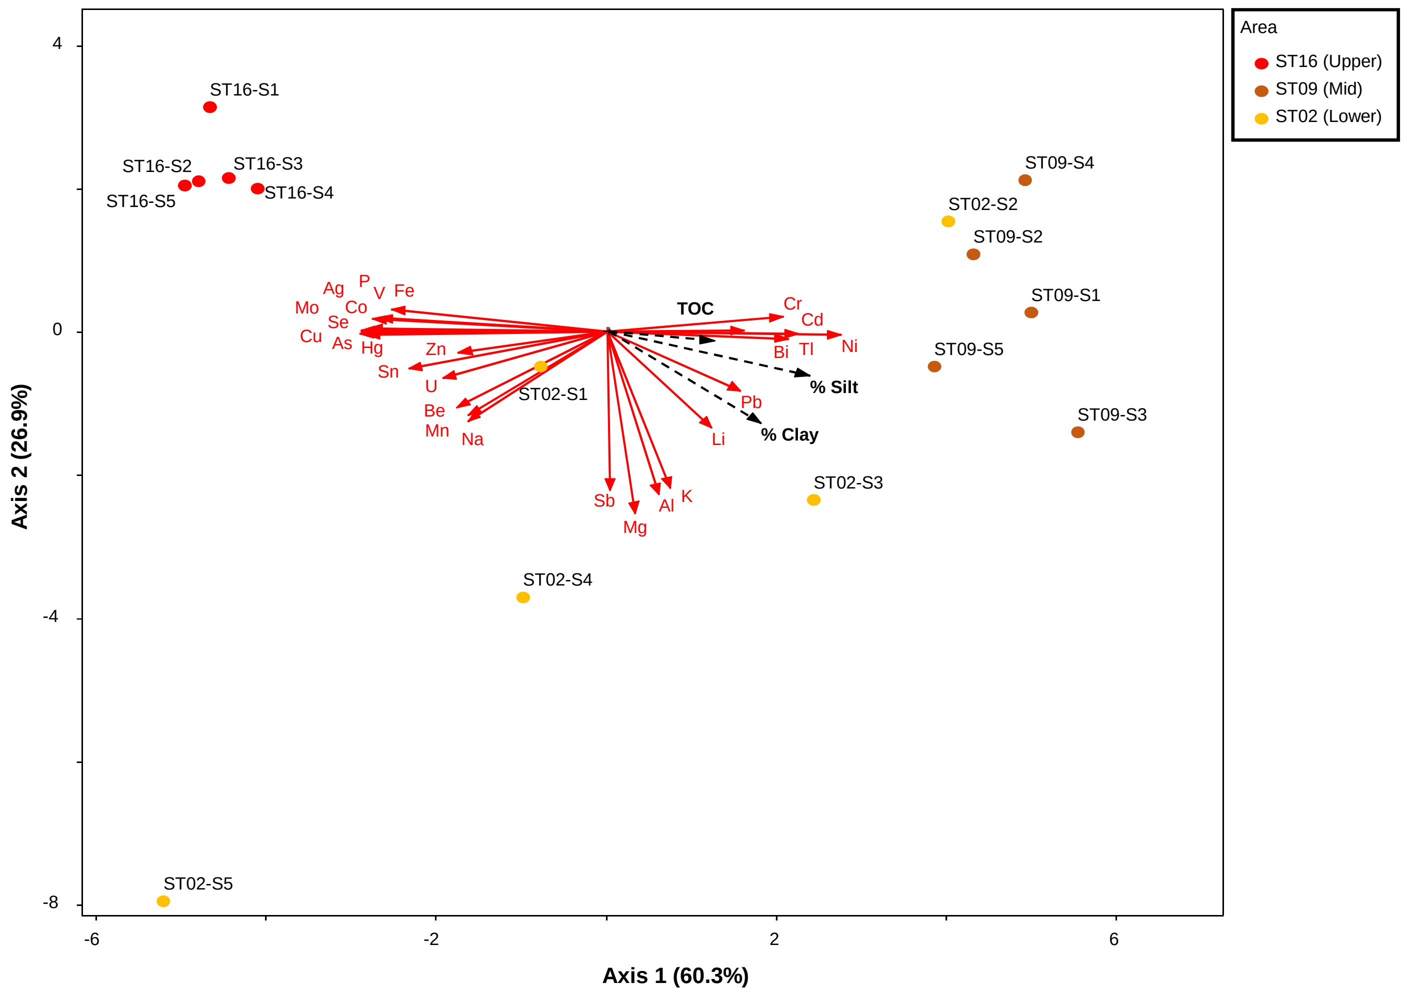

Figure E.3: Biplot of principal component analysis (PCA) of metal concentrations in sediment (<63 µm fraction) from Hazeltine Creek sampling stations, Mount Polley Mine, 2014. Vector length is proportional to the magnitude of direct correlation of metals (solid red vector lines) and indirect correlation of sediment physical characteristics (black dashed vector lines) with PCA values of each axis (Appendix Tables E.5-E.6). Only metals with significant (p-value <0.010) Spearman's correlation and r-values > 0.7 with either axis are displayed, all sediment physical characteristics are displayed.

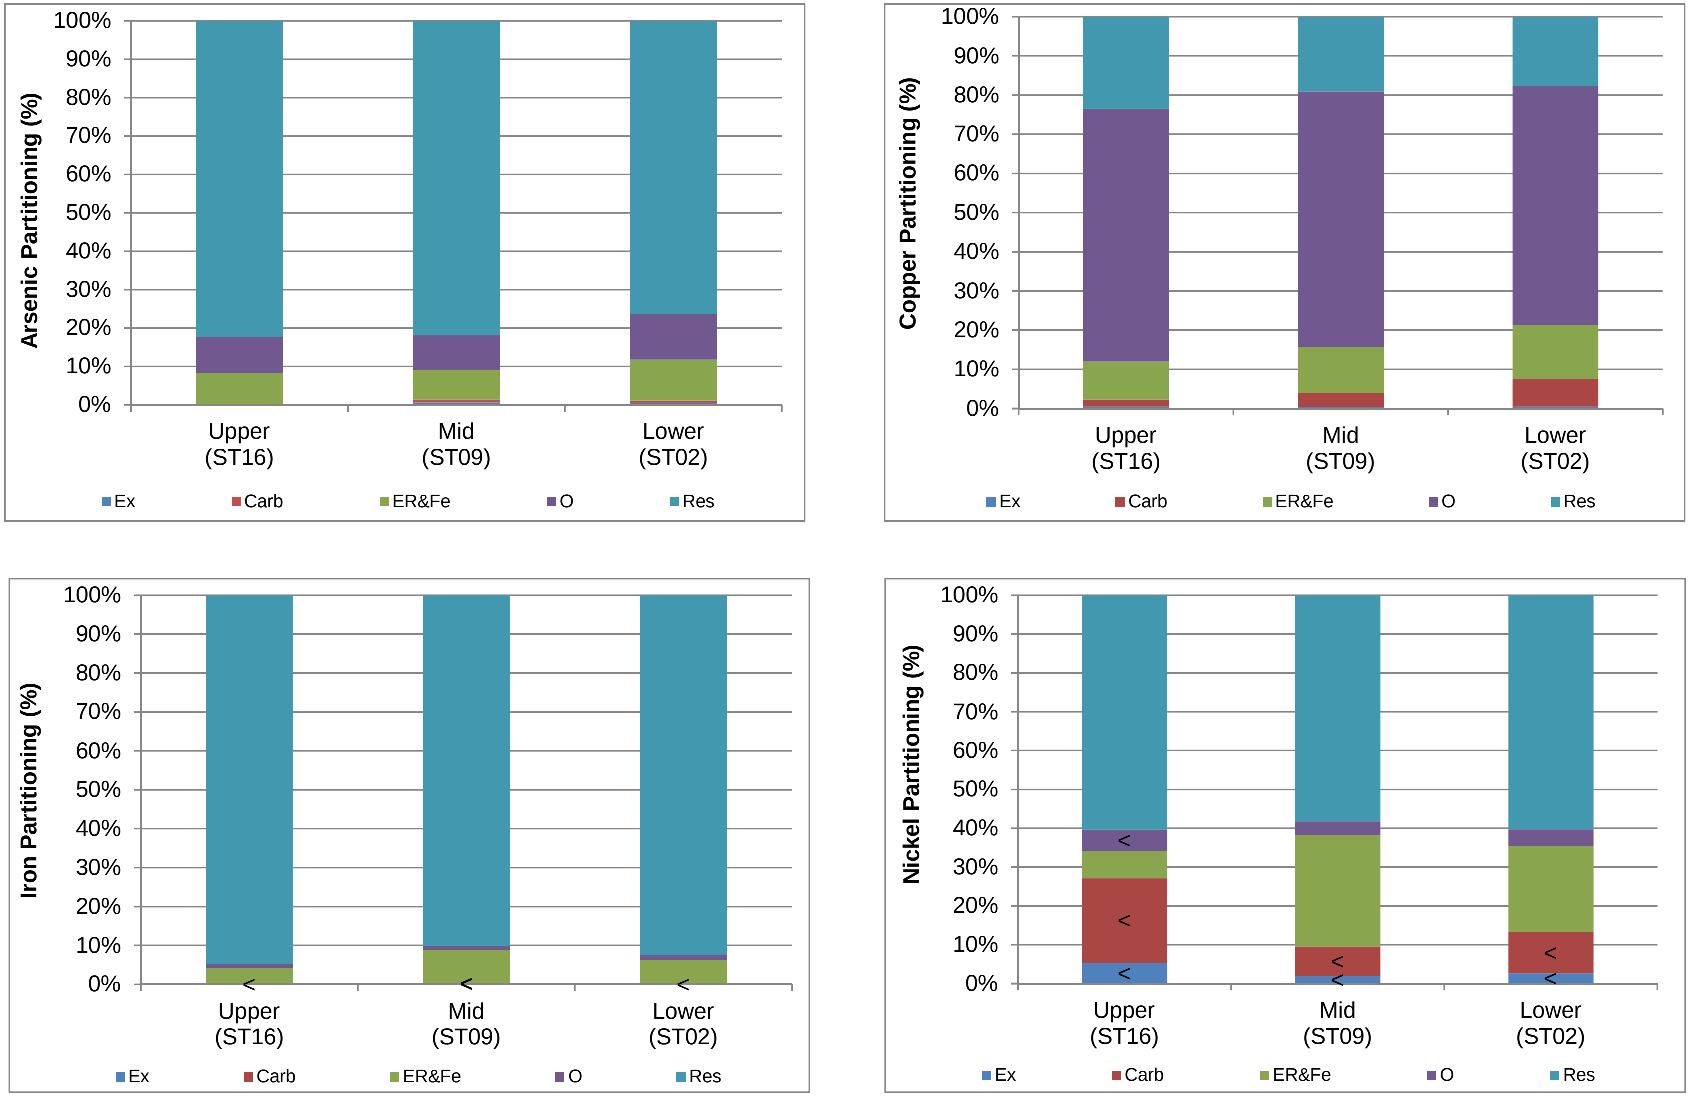

Figure E.4 (a): Partitioning of selectively extracted parameters of interest in sediment from Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic Bound Metals (O), and Residual Metals (Res).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL.

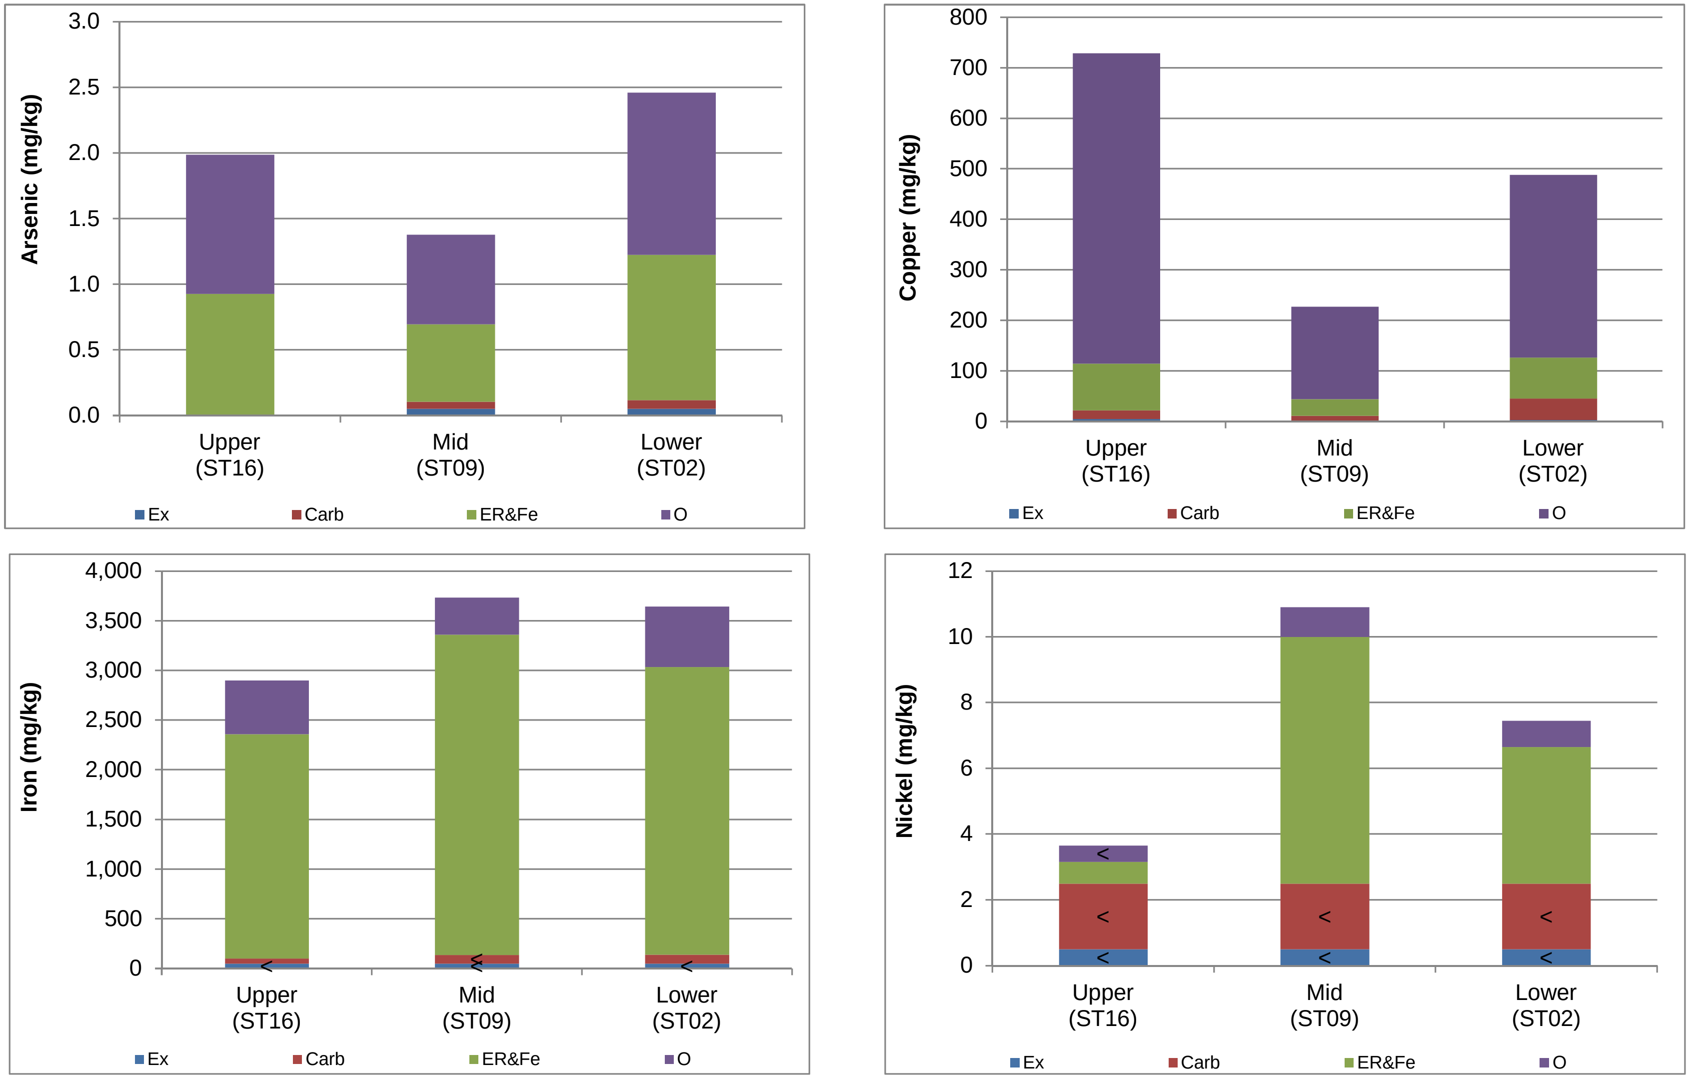

Figure E.4 (b): Mean concentrations of selectively extracted parameters of interest in sediment from Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) and Organic Bound Metals (O) fractions are shown (Residual metals are excluded).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL.

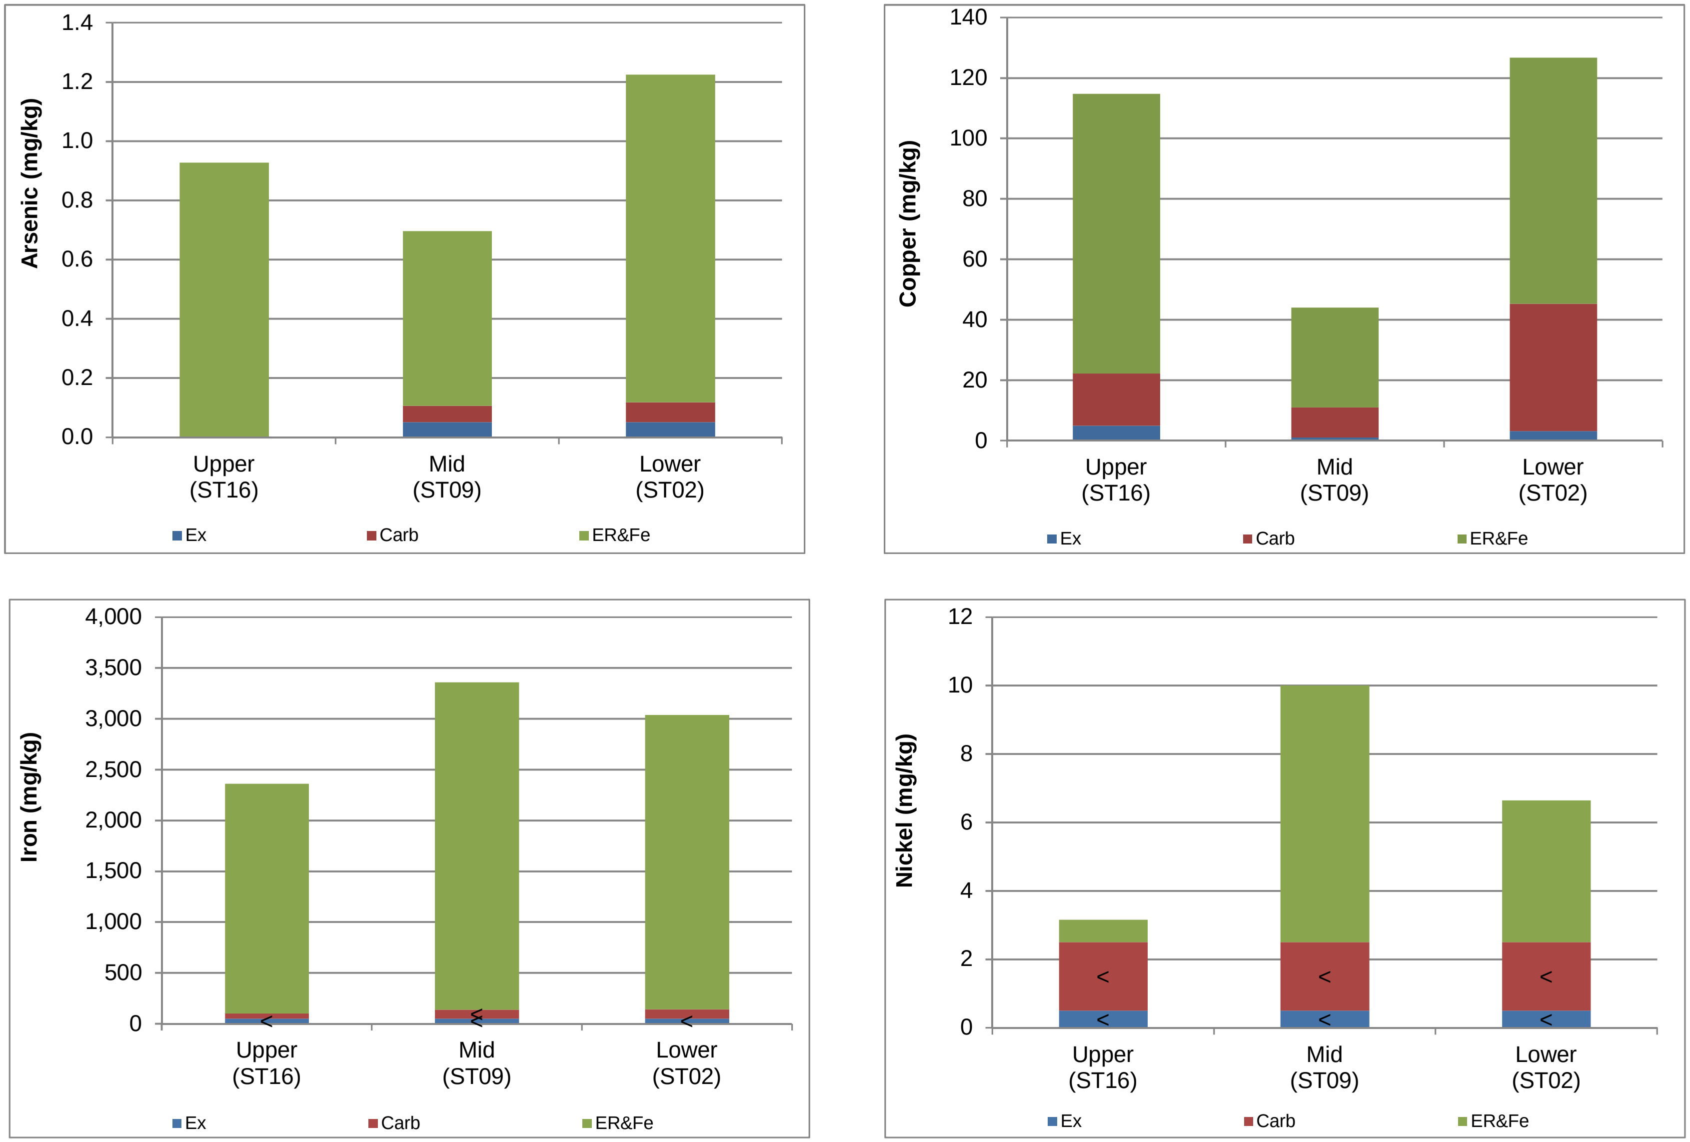

Figure E.4 (c): Mean concentrations of selectively extracted parameters of interest in sediment from Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) fractions are shown (Organic Bound and Residual metals are excluded).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL.

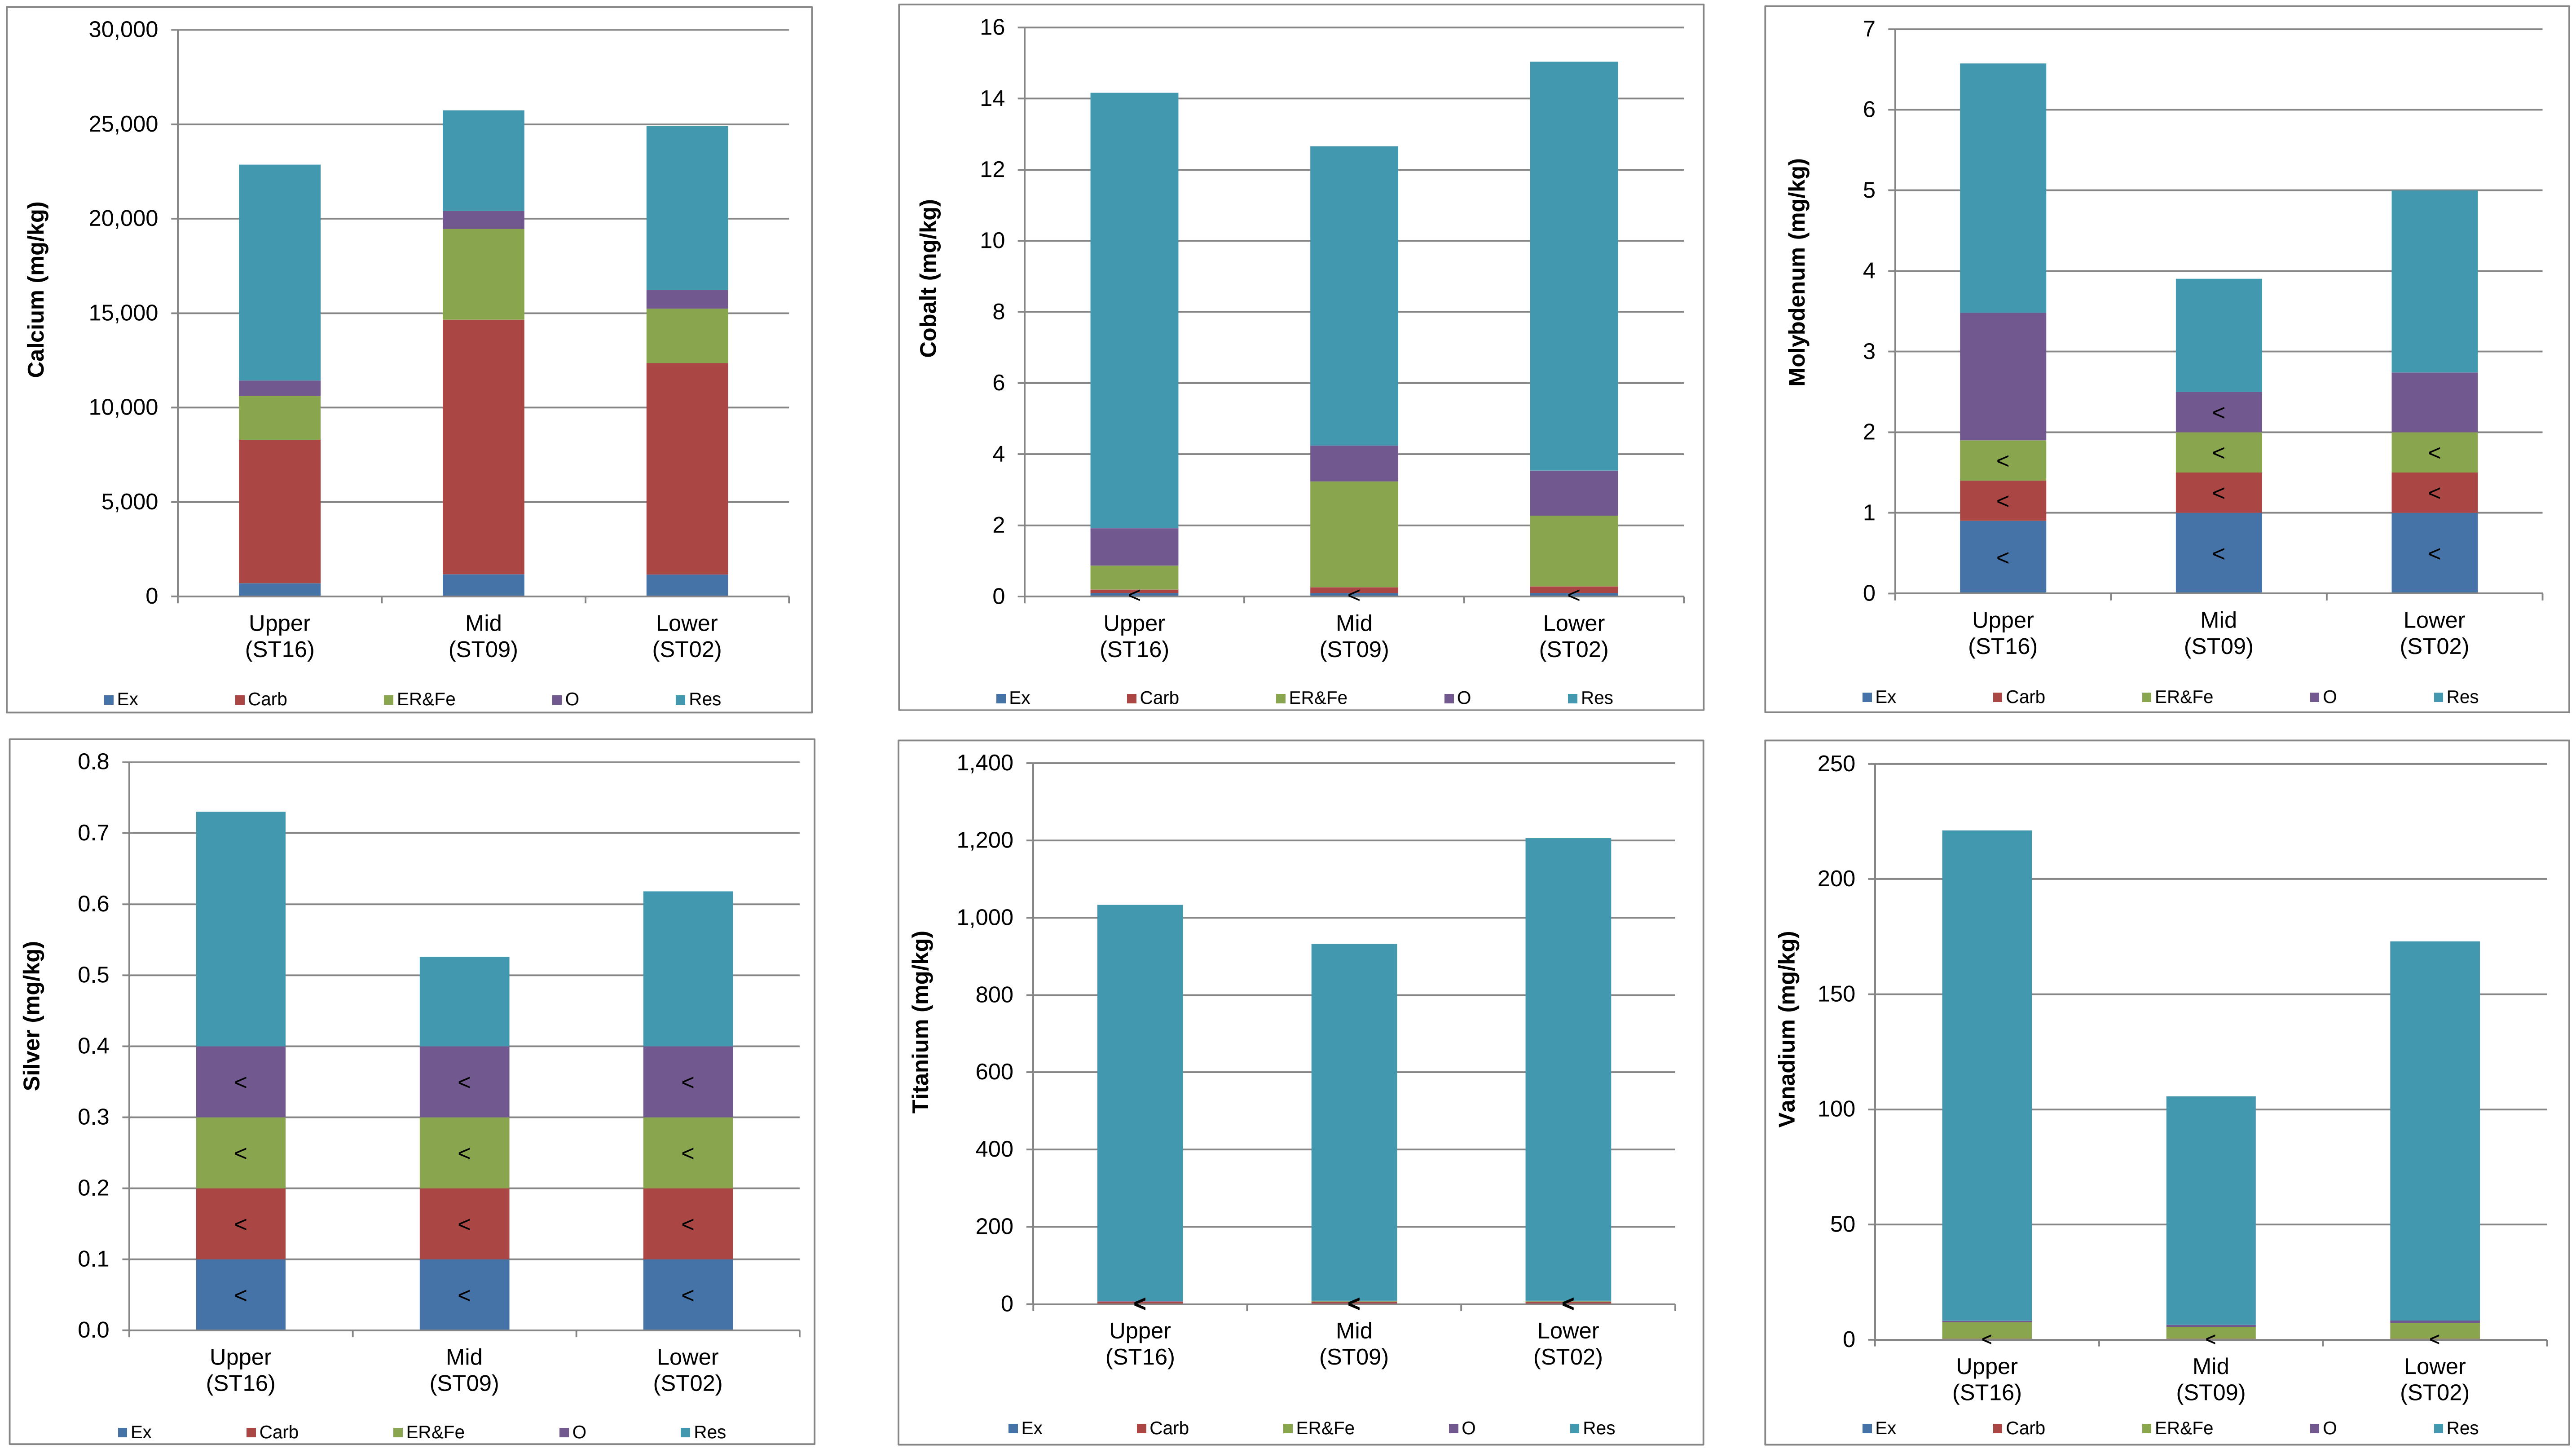

Figure E.5 (a): Mean concentrations of selectively extracted indicator parameters in sediment from Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic Bound Metals (O), and Residual Metals (Res).

Values < MDL are indicated with a < symbol. Data for boron were not available, sodium data were available only for the Ex fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result. Phosphorus data was only available for Ex, Carb, and ER&Fe fractions and was not plotted as a result.

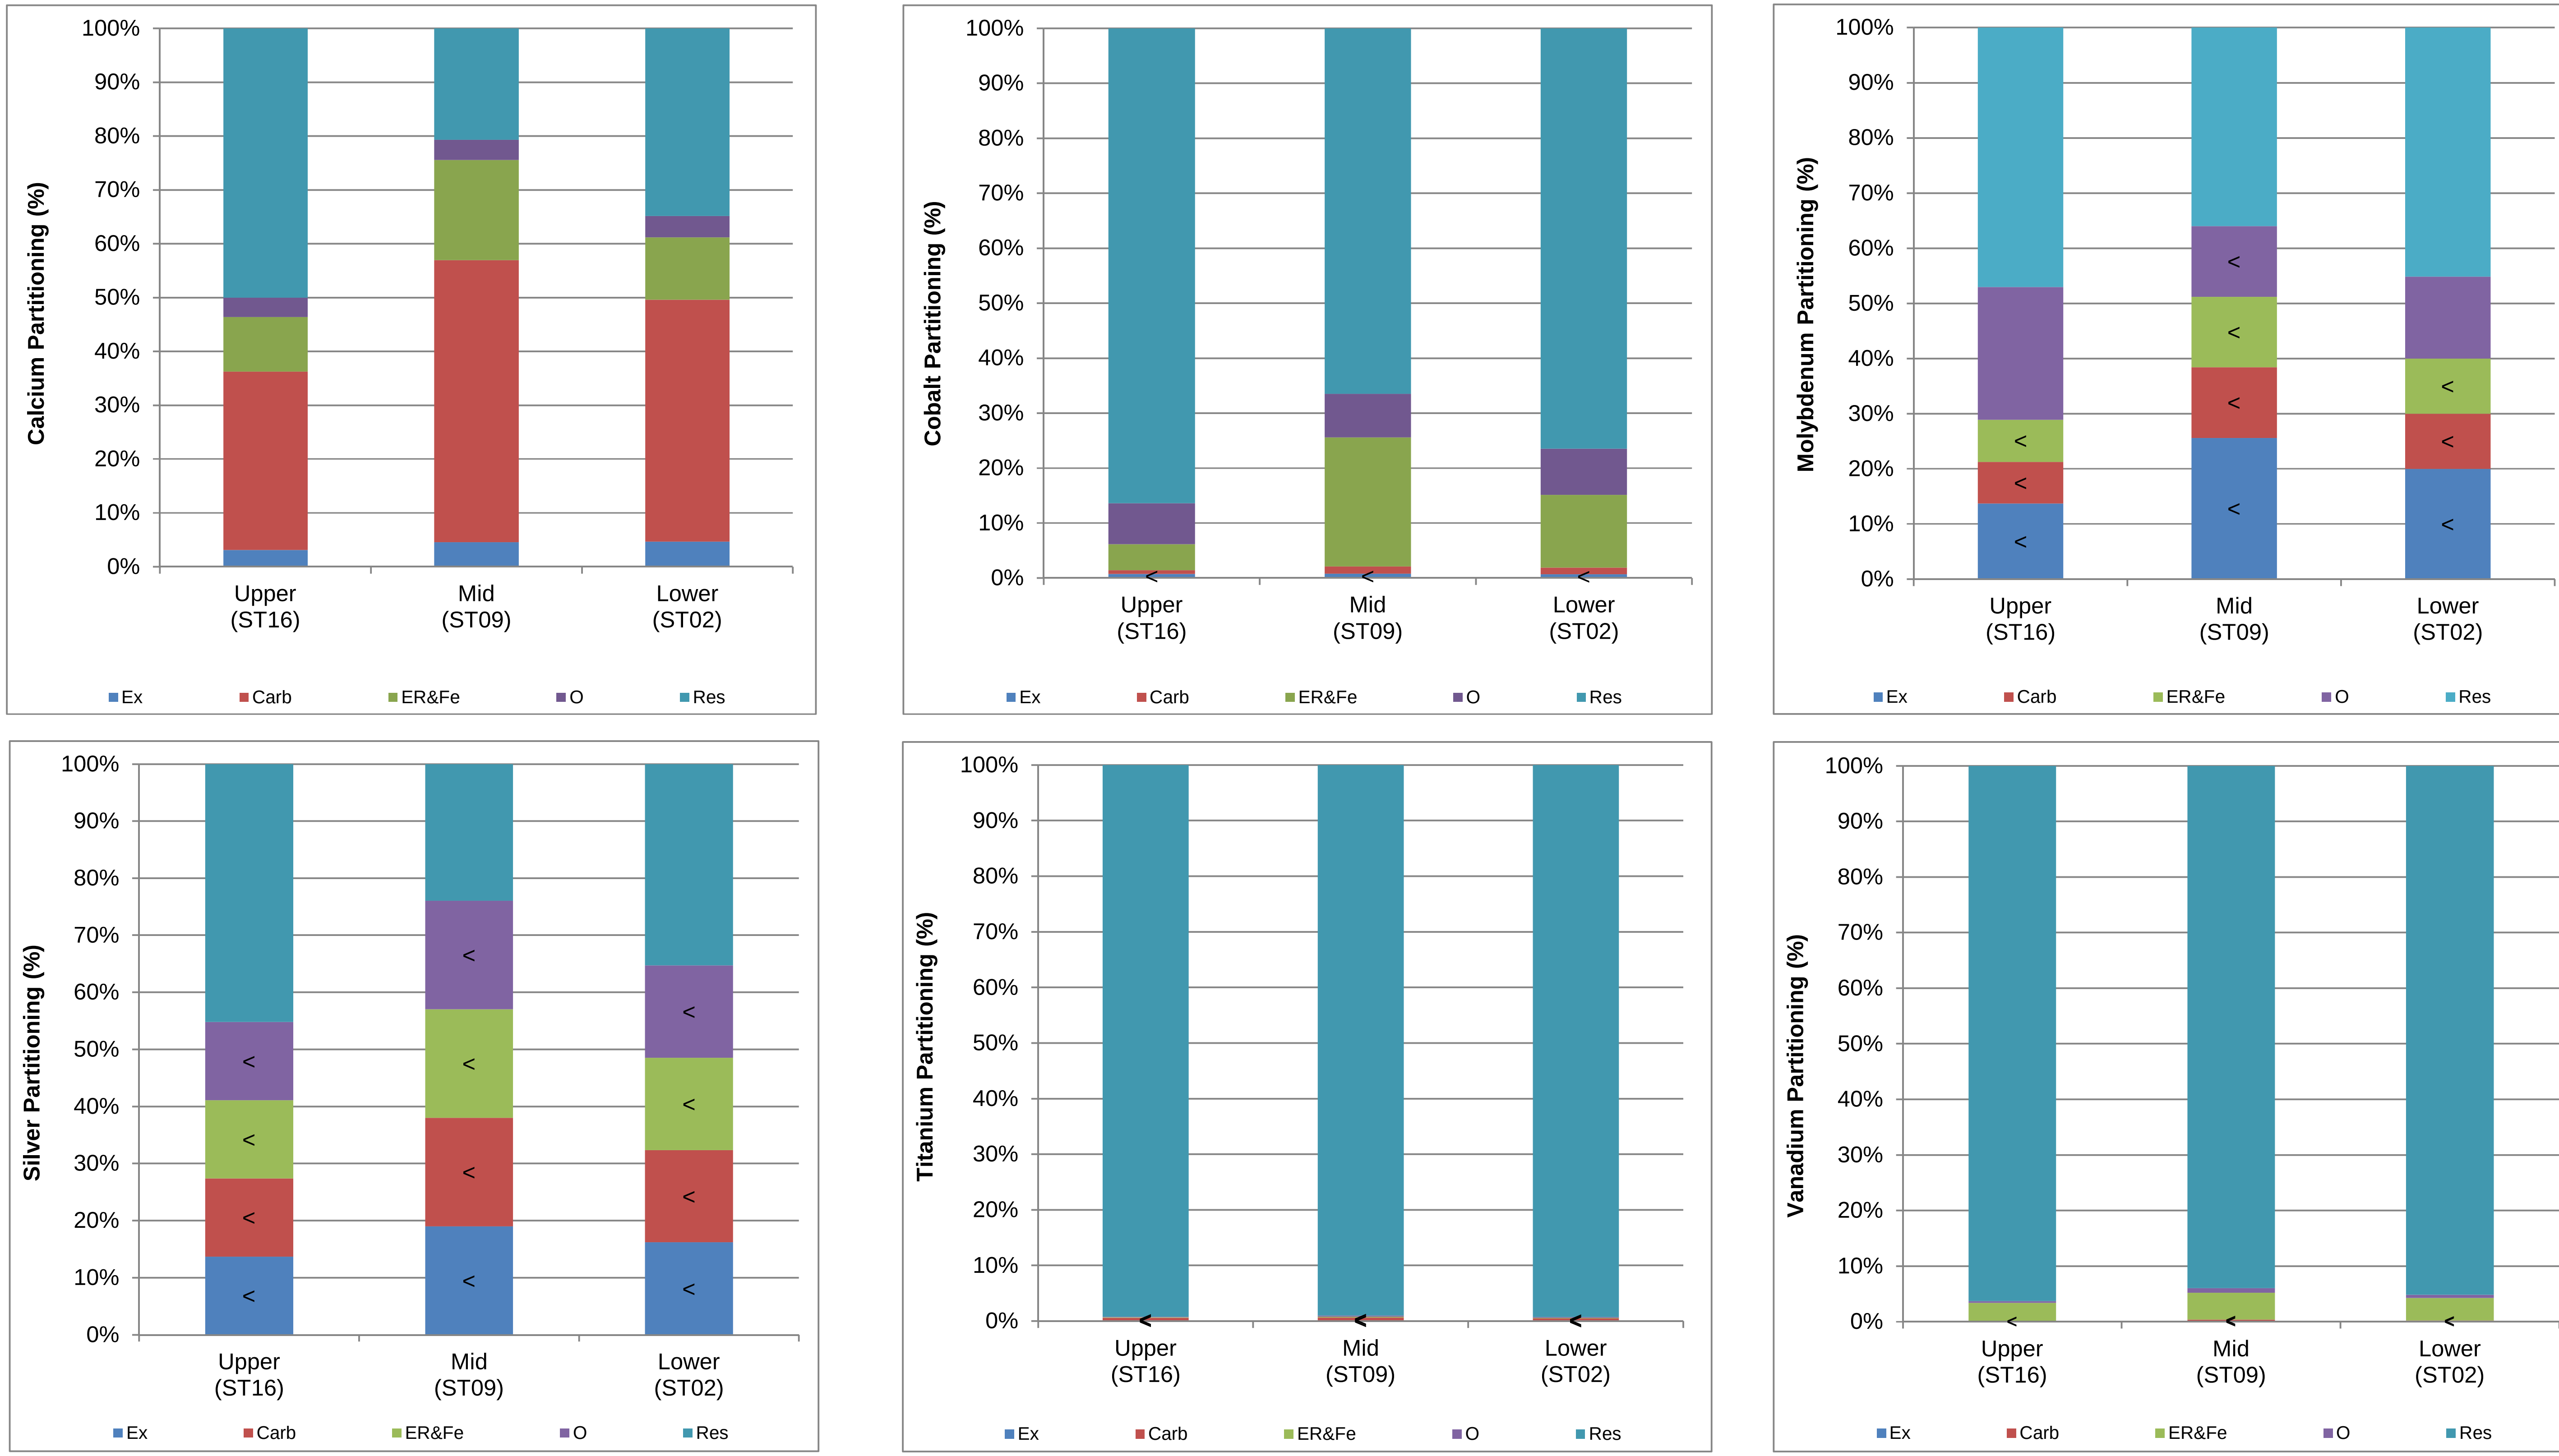

Figure E.5 (b): Partitioning of indicator parameters within selectively extracted fractions of sediment from Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic Bound Metals (O), and Residual Metals (Res).

Values < MDL are indicated with a < symbol. Data for boron were not available, sodium data were available only for the Ex fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result. Phosphorus data was only available for Ex, Carb, and ER&Fe fractions and was not plotted as a result.

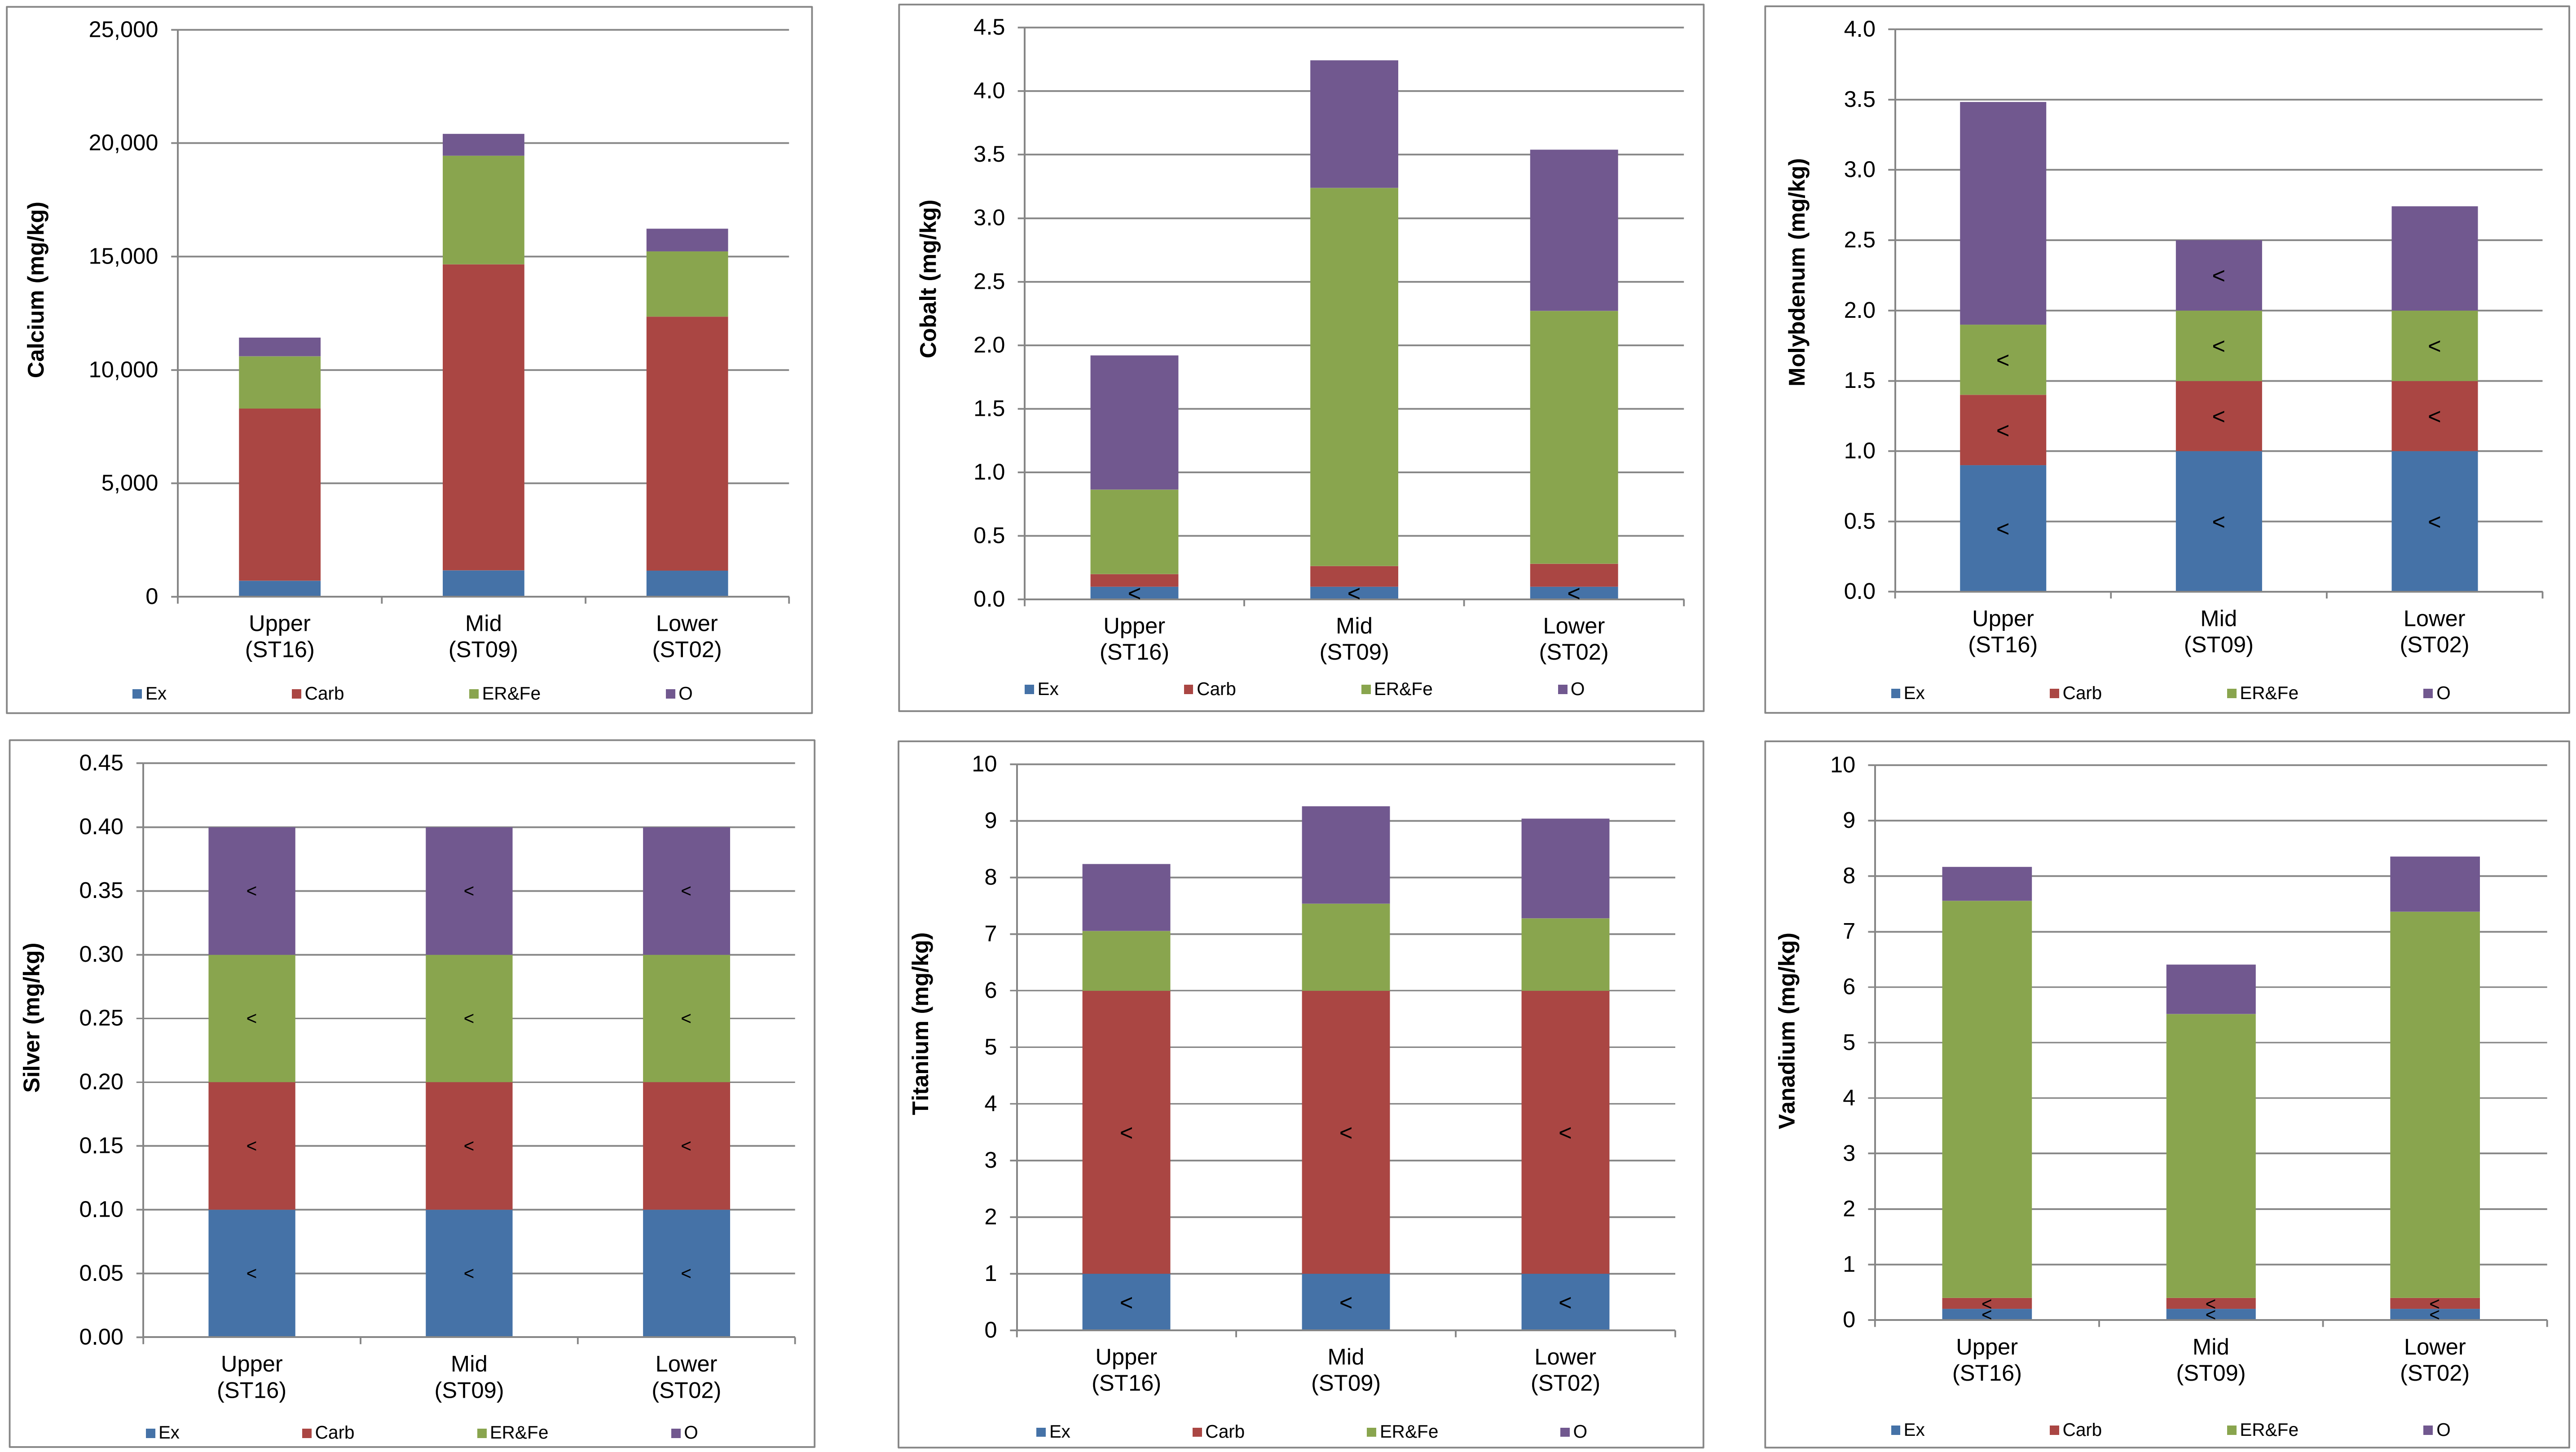

Figure E.5 (c): Mean concentrations of selectively extracted indicator parameters in sediment from Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) and Organic Bound Metals (O) fractions are shown (Residual metals are excluded).

Values < MDL are indicated with a < symbol. Data for boron were not available, sodium data were available only for the Ex fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result. Phosphorus data was only available for Ex, Carb, and ER&Fe fractions and was not plotted as a result.

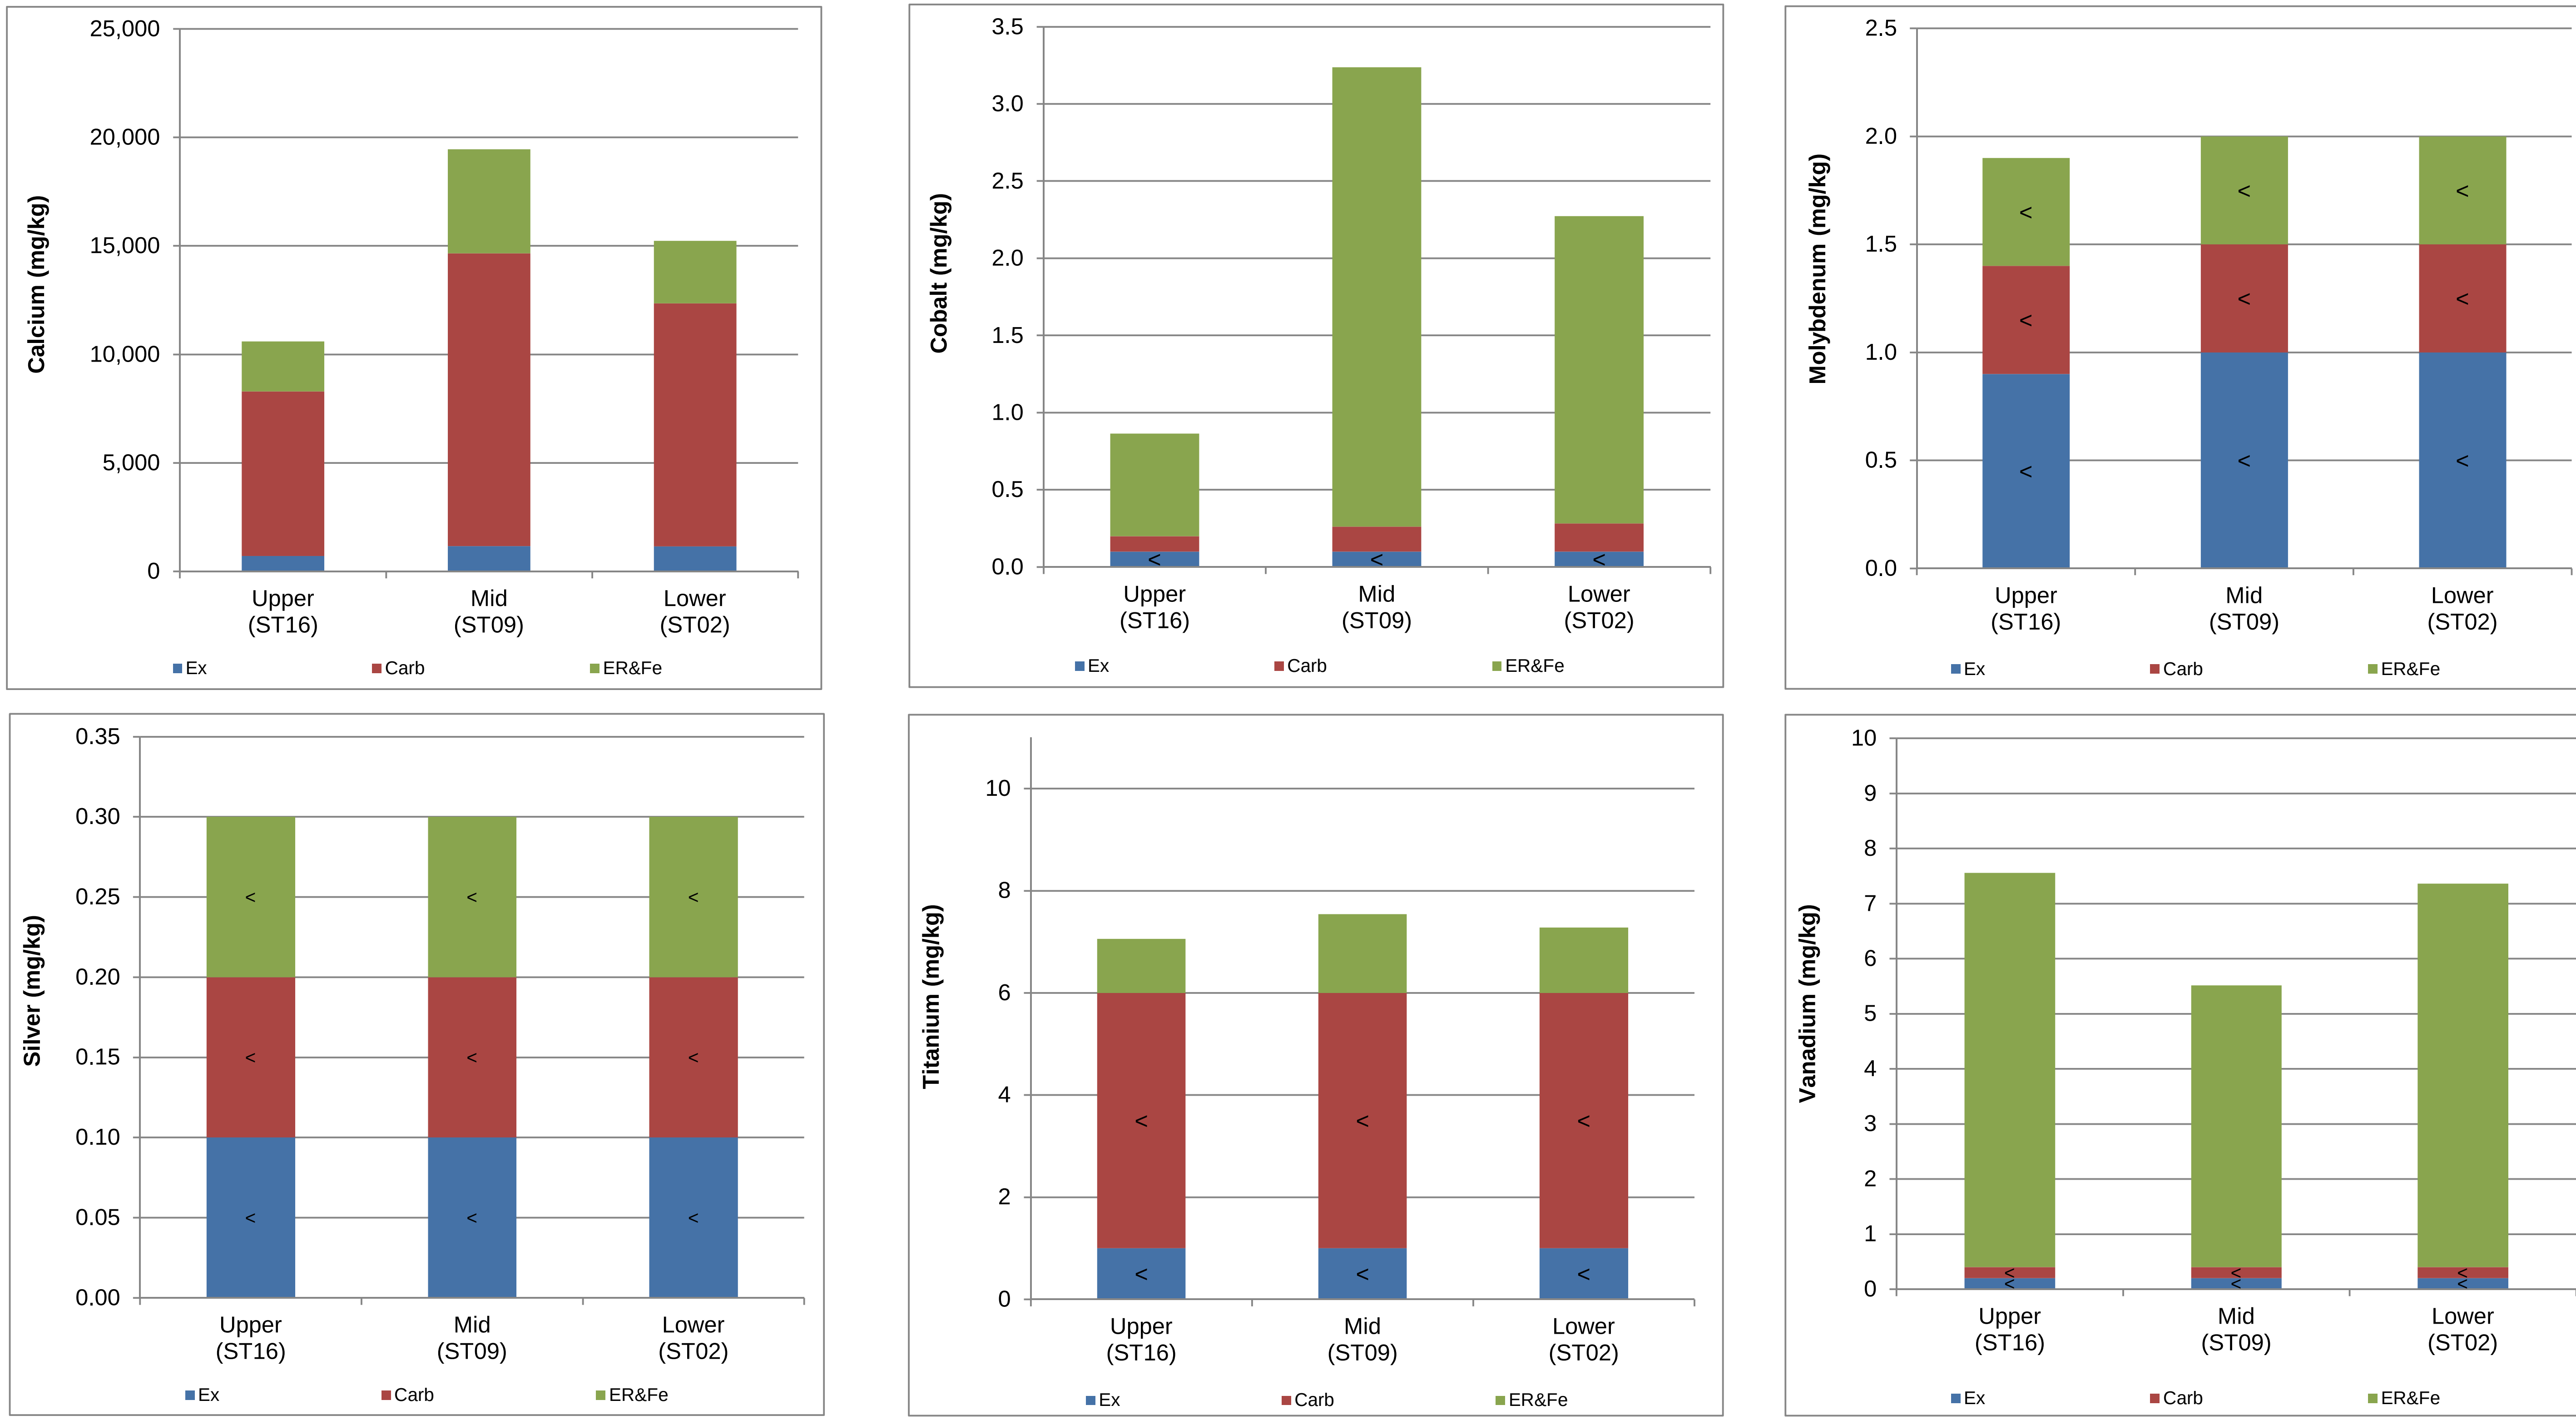

Figure E.5 (d): Mean concentrations of selectively extracted indicator parameters in sediment from Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) fractions are shown (Organic Bound and Residual metals are excluded).

Values < MDL are indicated with a < symbol. Data for boron were not available, sodium data were available only for the Ex fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result. Phosphorus data was only available for Ex, Carb, and ER&Fe fractions and was not plotted as a result.

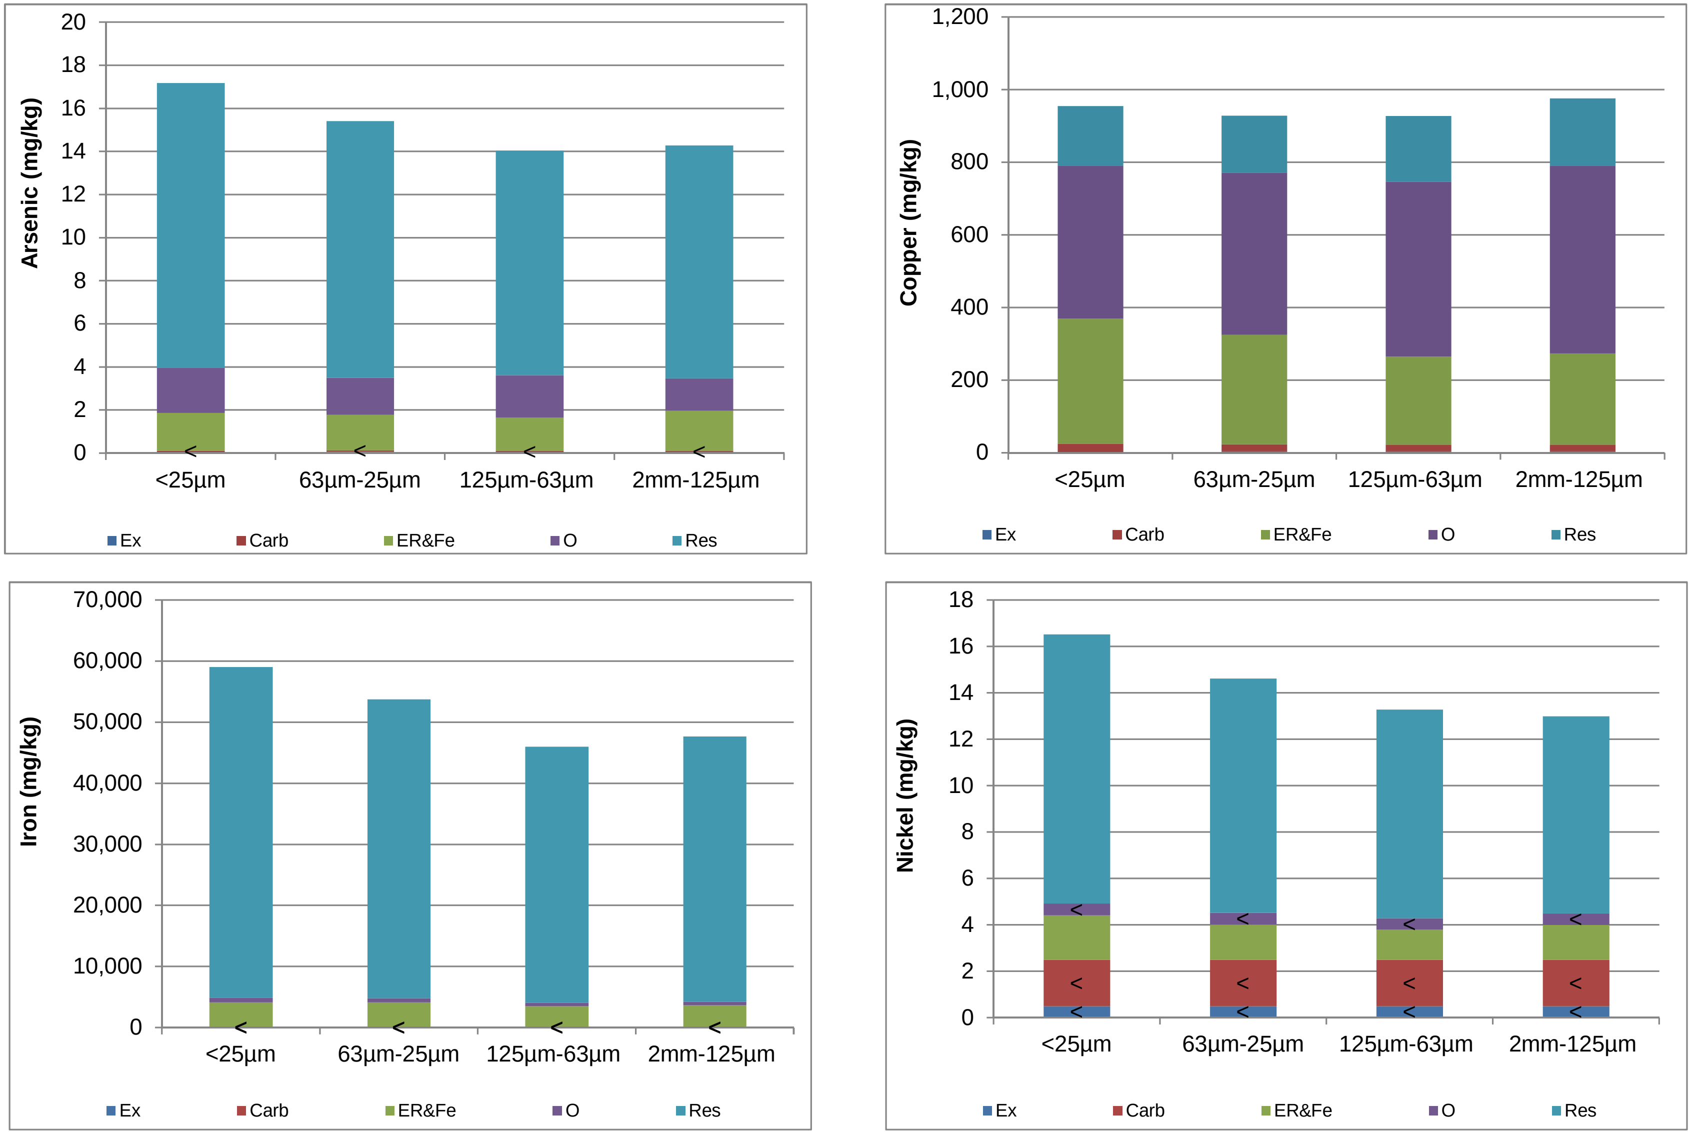

Figure E.6 (a): Mean concentrations of selectively extracted parameters of interest in sediment from Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) and Organic Bound Metals (O) fractions are shown (Residual metals are excluded).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL.

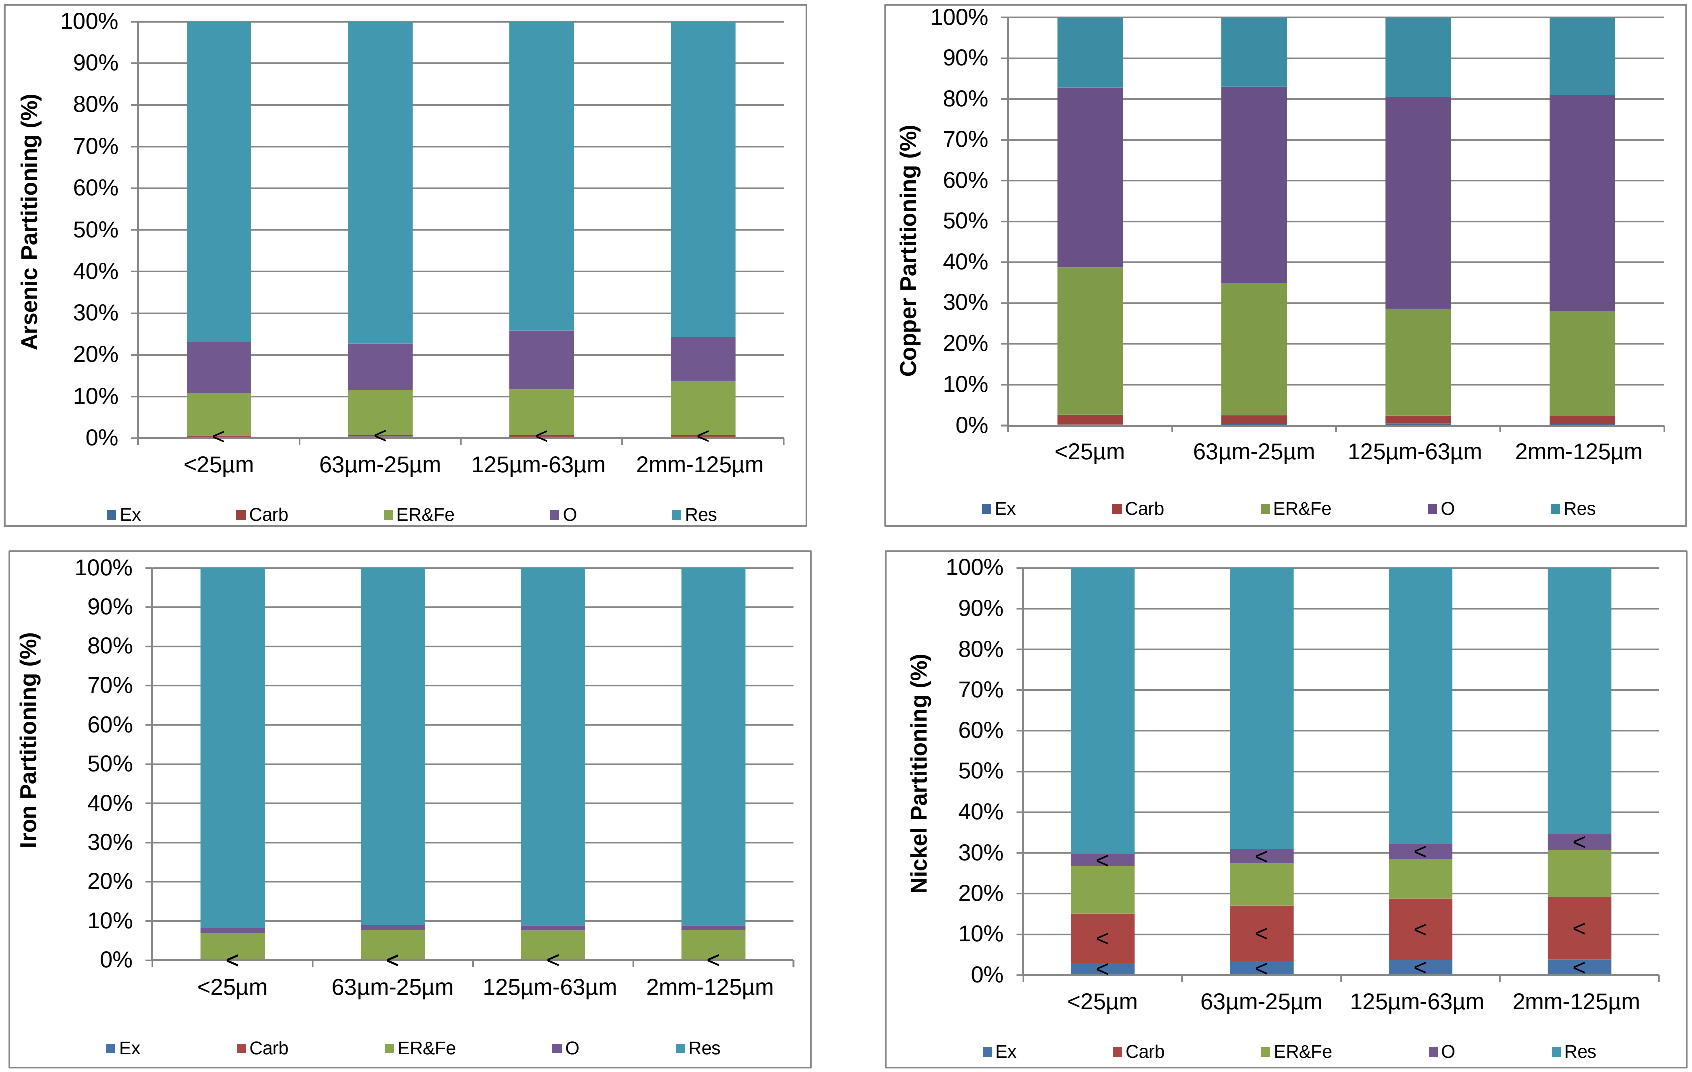

Figure E.6 (b): Partitioning of selectively extracted parameters of interest in sediment from Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic Bound Metals (O), and Residual Metals (Res).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL.

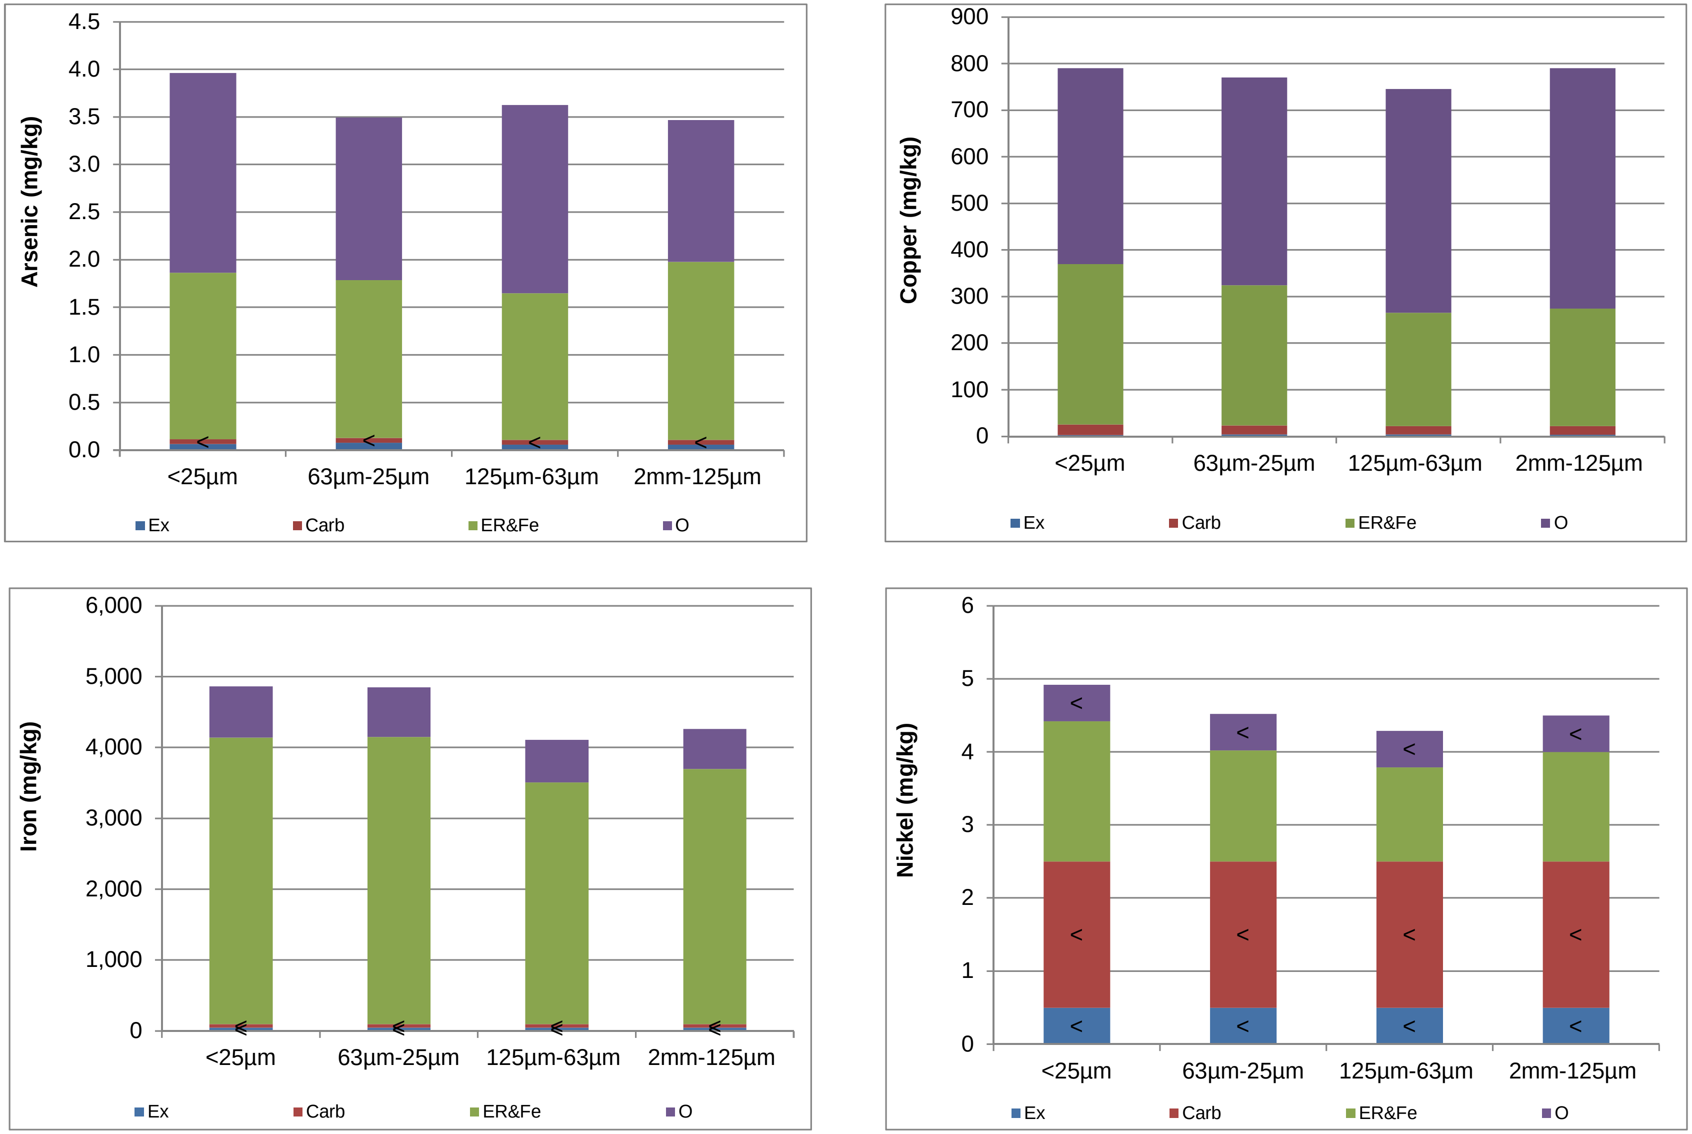

Figure E.6 (c): Mean concentrations of selectively extracted parameters of interest in sediment from Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) and Organic Bound Metals (O) fractions are shown (Residual metals are excluded).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL.

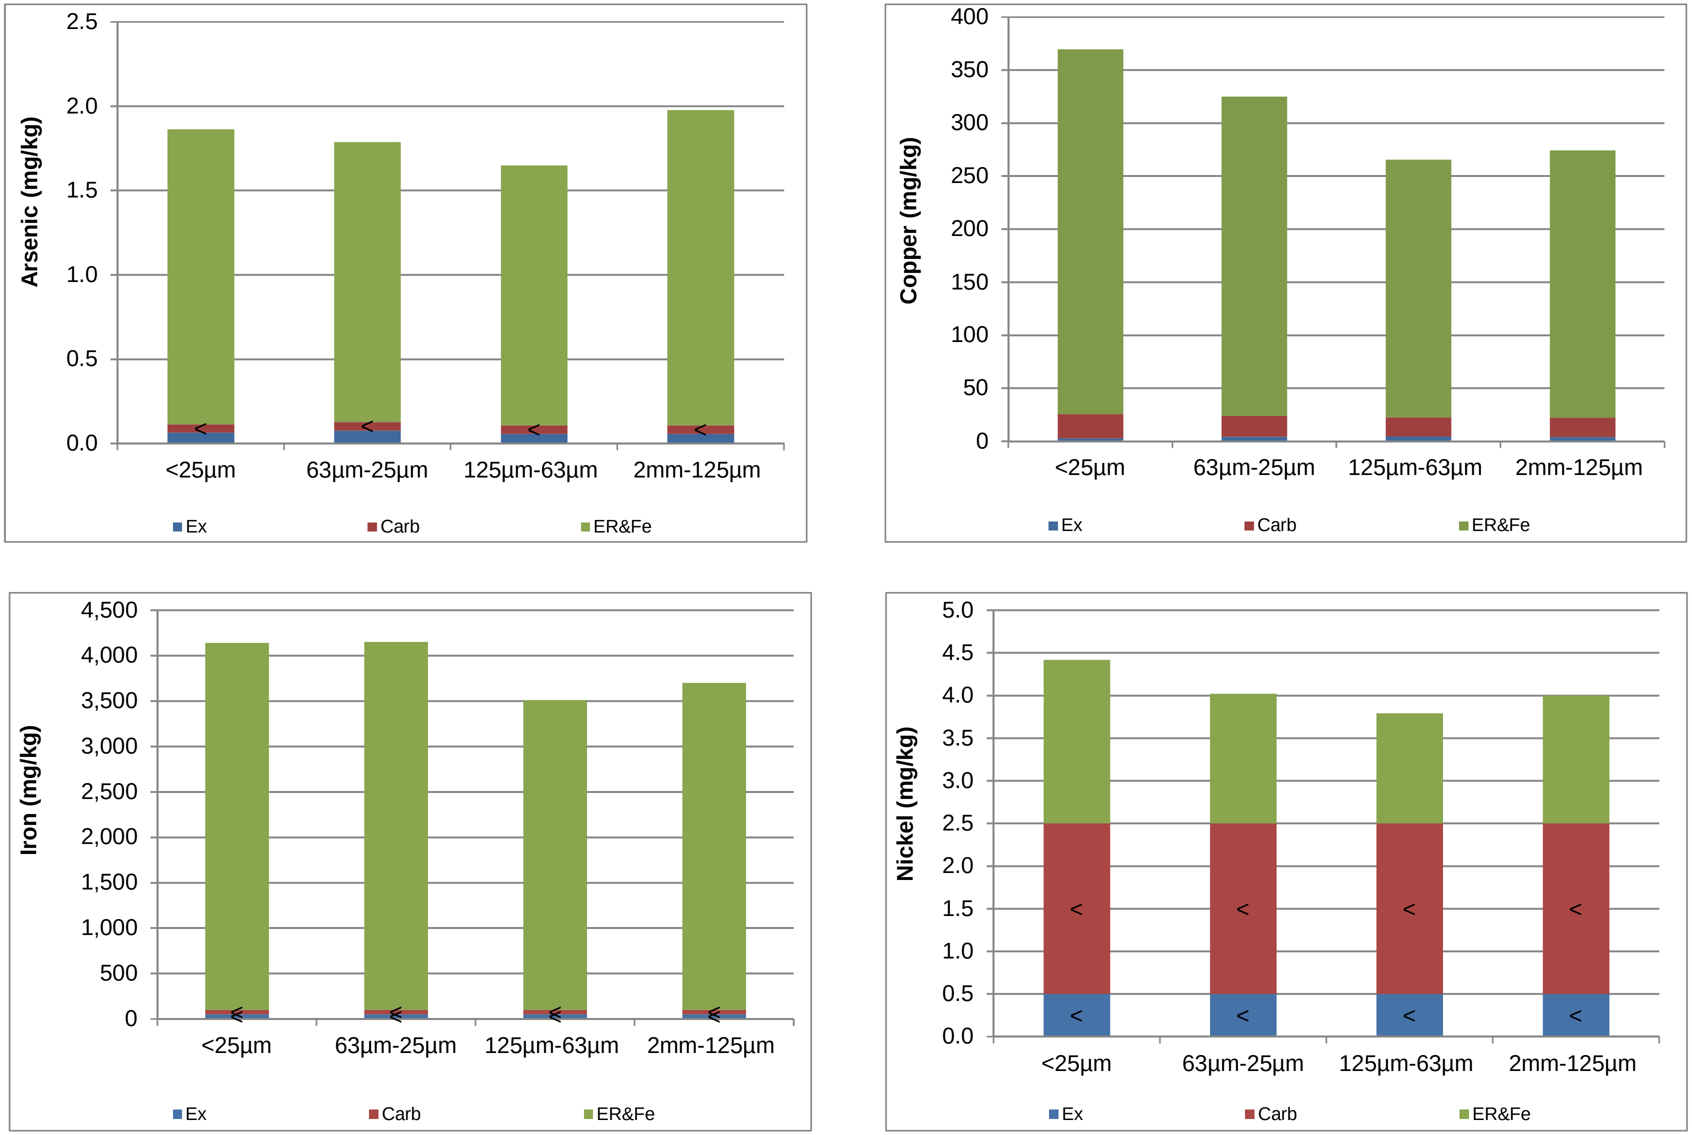

Figure E.6 (d): Mean concentrations of selectively extracted parameters of interest in sediment from Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) fractions are shown (Organic Bound and Residual metals are excluded).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL.

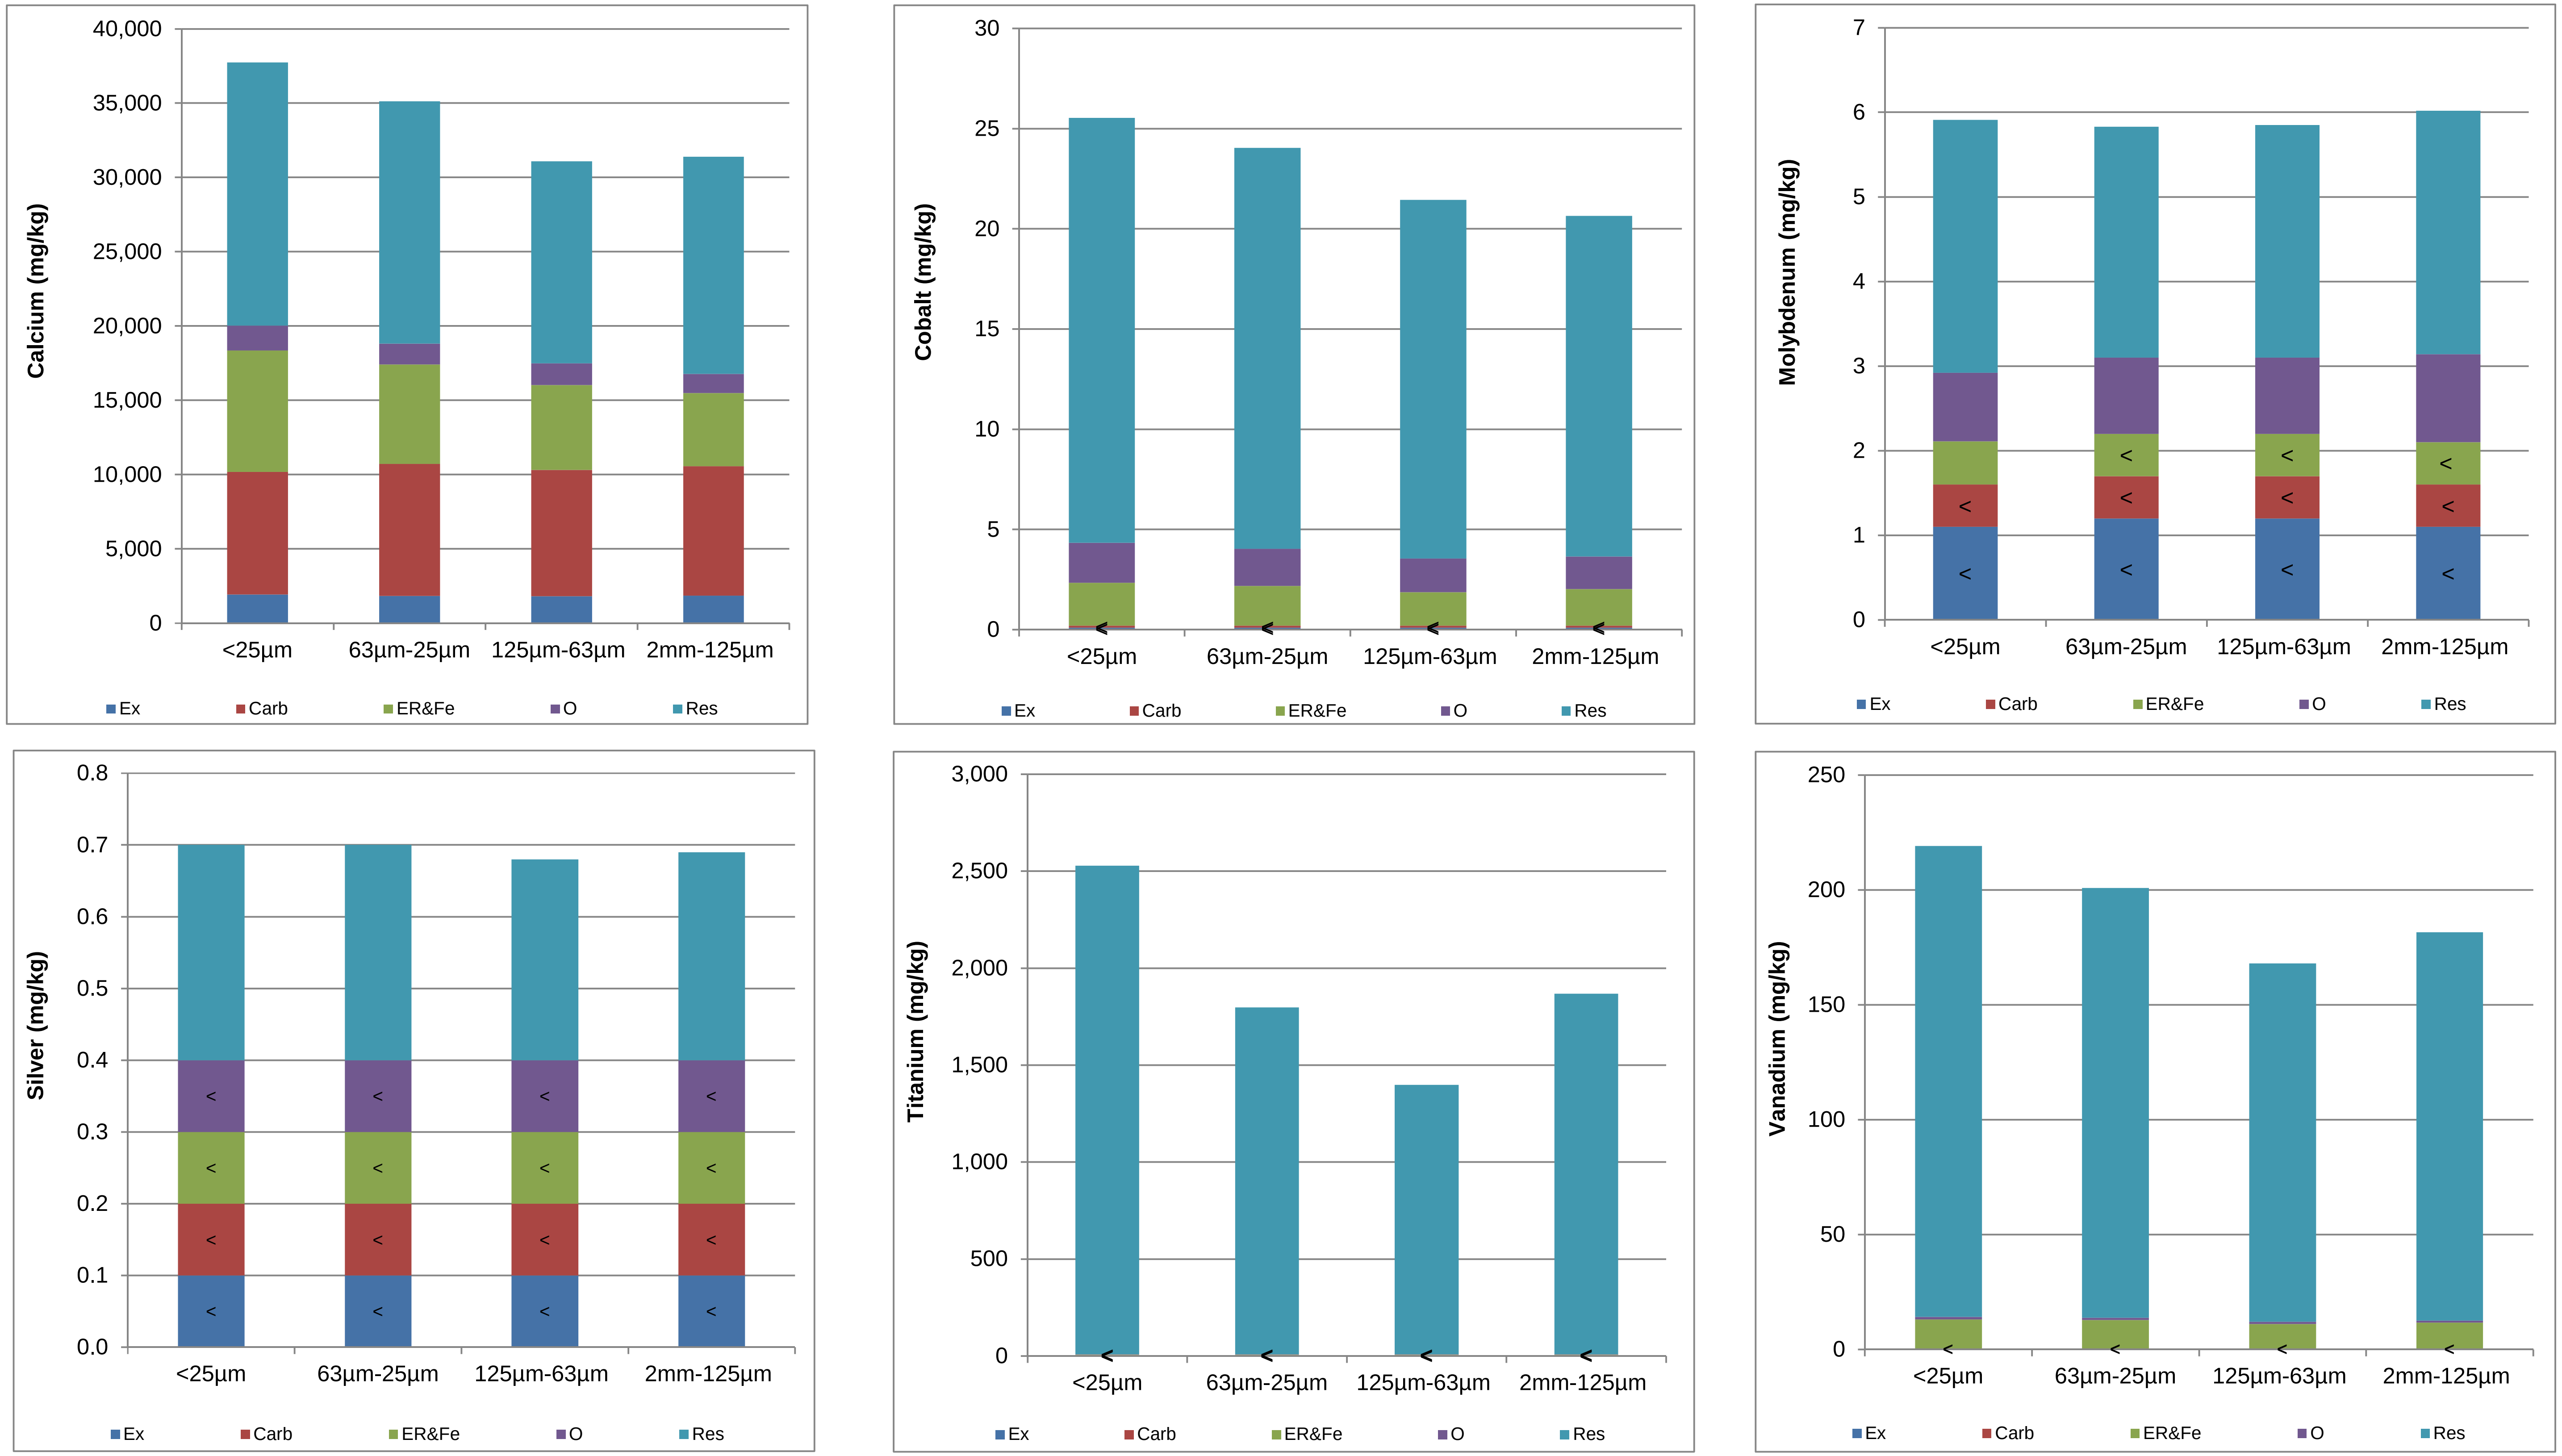

Figure E.7 (a): Concentrations of selectively extracted indicator parameters in Hazeltine Creek size-fractioned sediment HAC50, Mount Polley Mine, 2014. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic Bound Metals (O), and Residual Metals (Res).

Values < MDL are indicated with a < symbol. Data for boron were not available, sodium data were available only for the Ex fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result. Phosphorus data was only available for Ex, Carb, and ER&Fe fractions and was not plotted as a result.

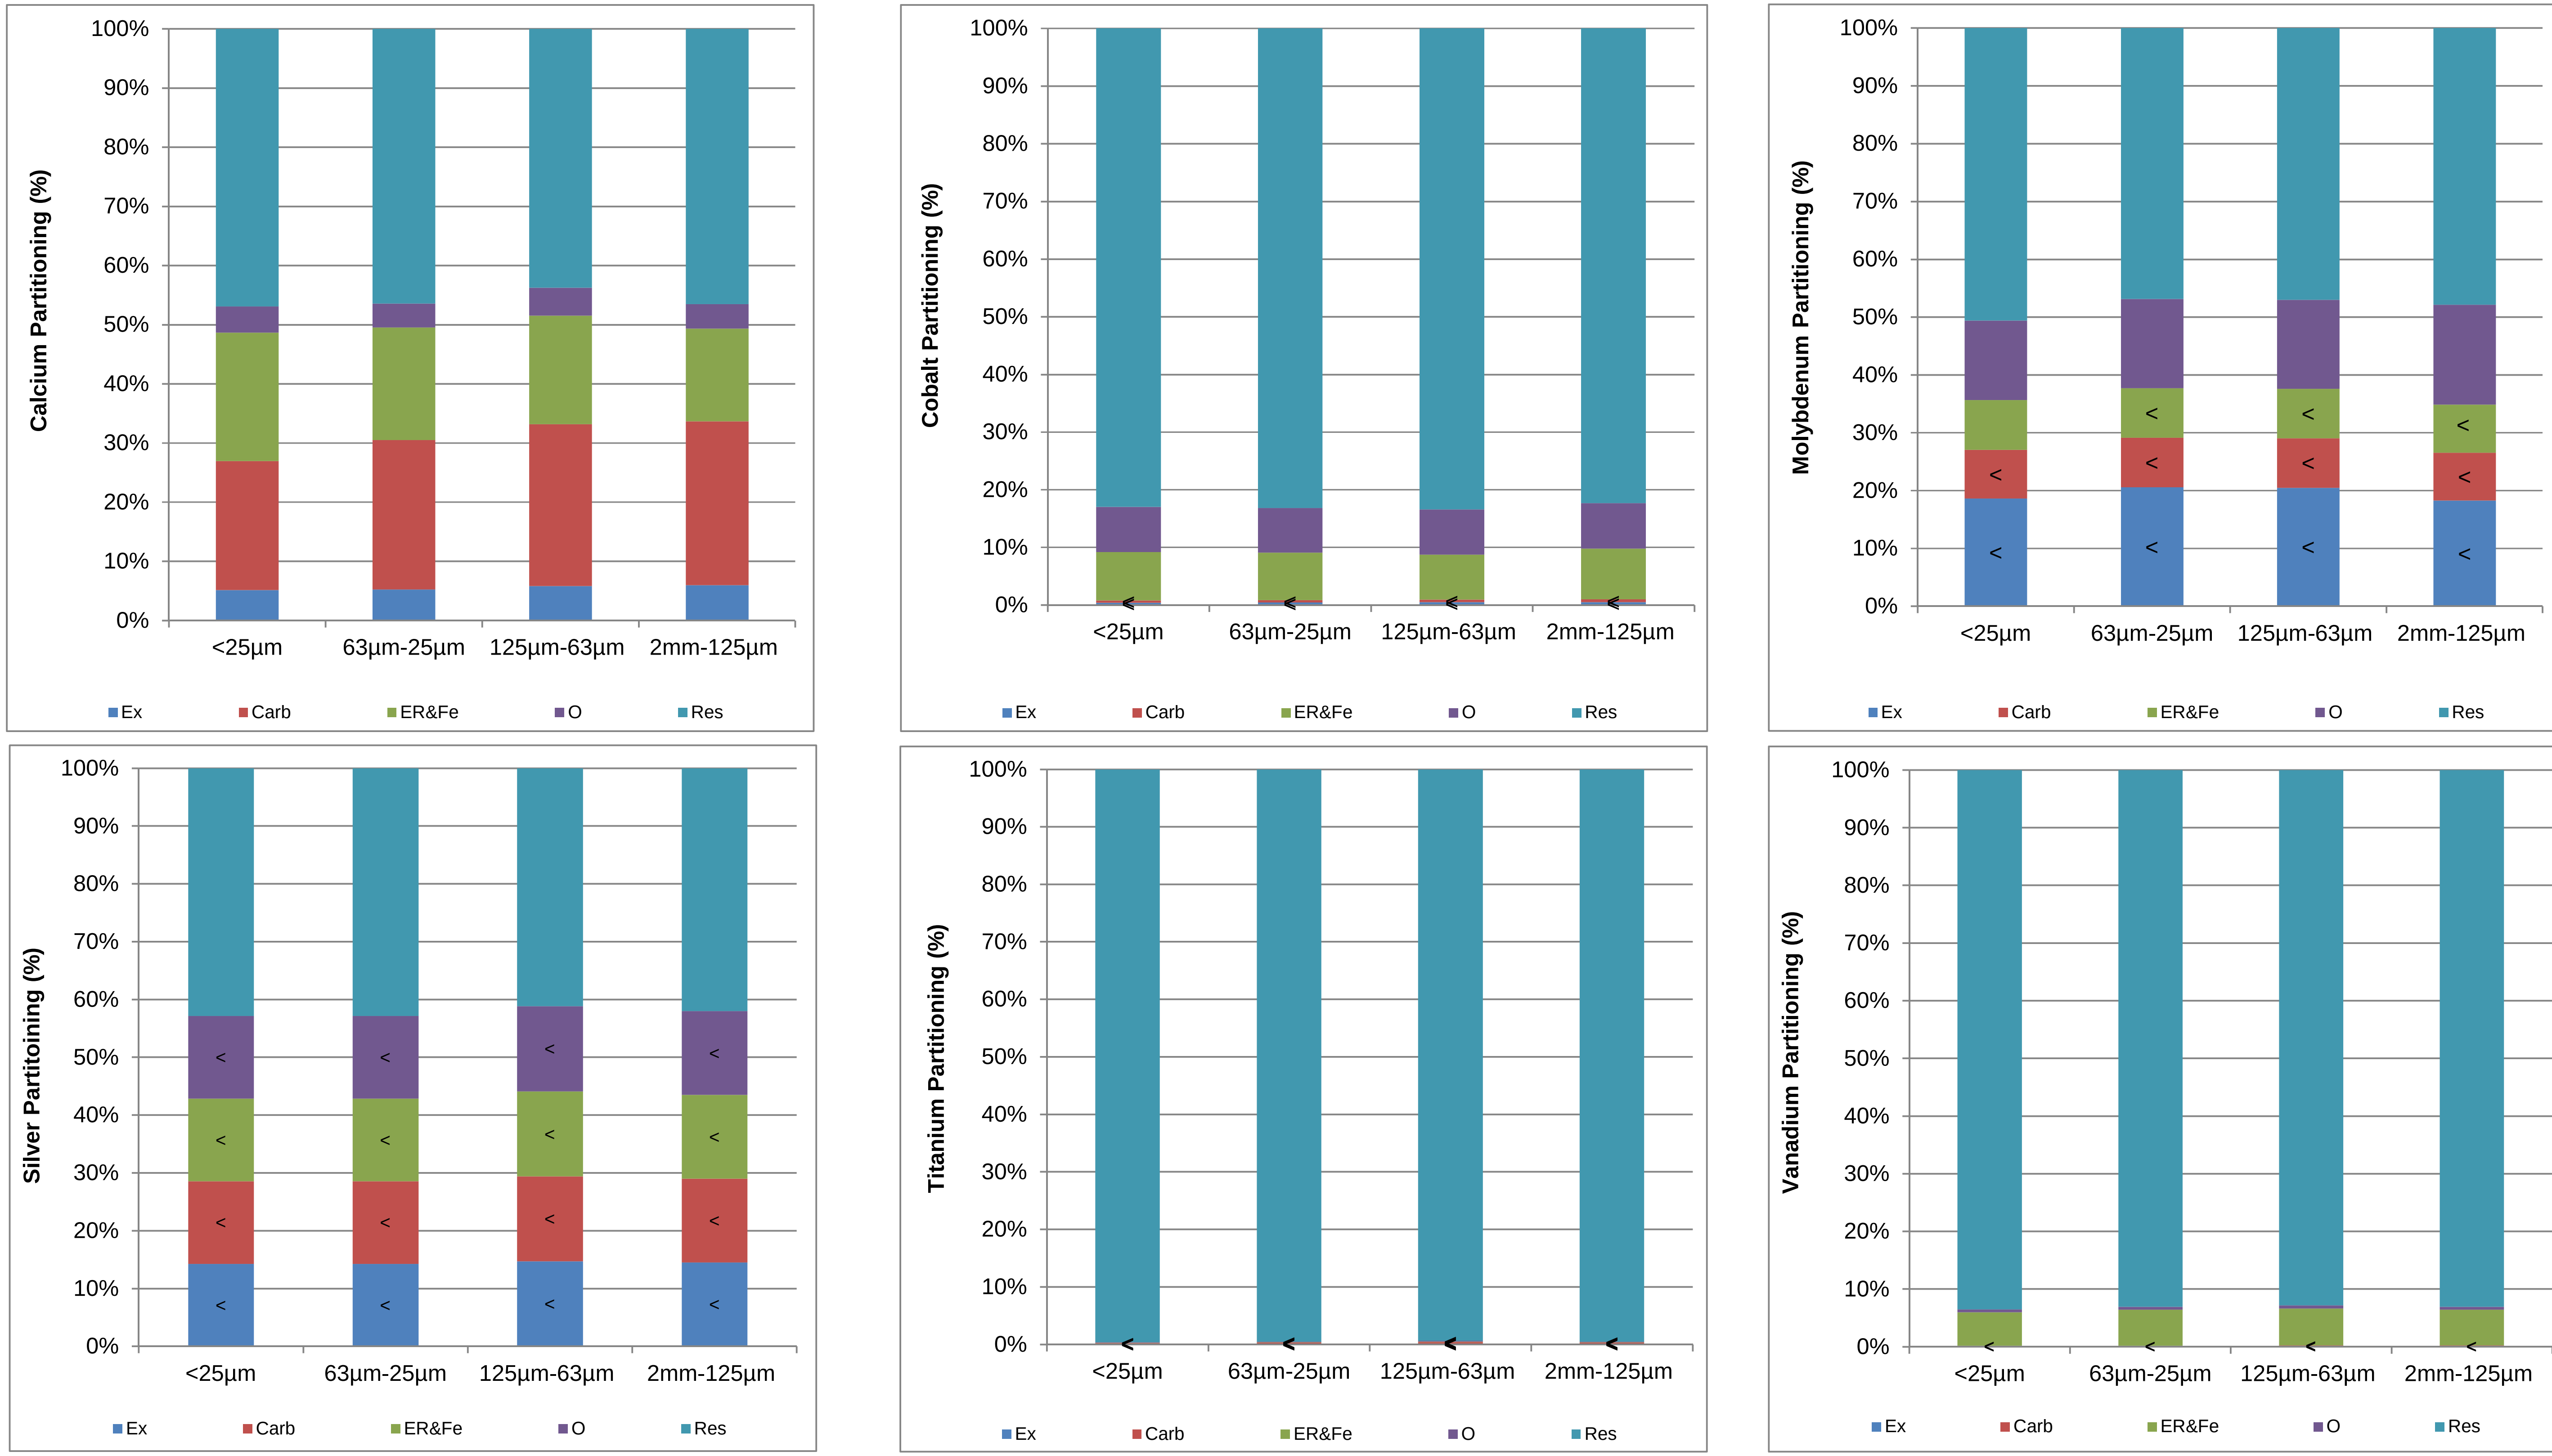

Figure E.7 (b): Partitioning of indicator parameters in Hazeltine Creek size-fractioned sediment sample HAC50, Mount Polley Mine, 2014. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic Bound Metals (O), and Residual Metals (Res).

Values < MDL are indicated with a < symbol. Data for boron were not available, sodium data were available only for the Ex fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result. Phosphorus data was only available for Ex, Carb, and ER&Fe fractions and was not plotted as a result.

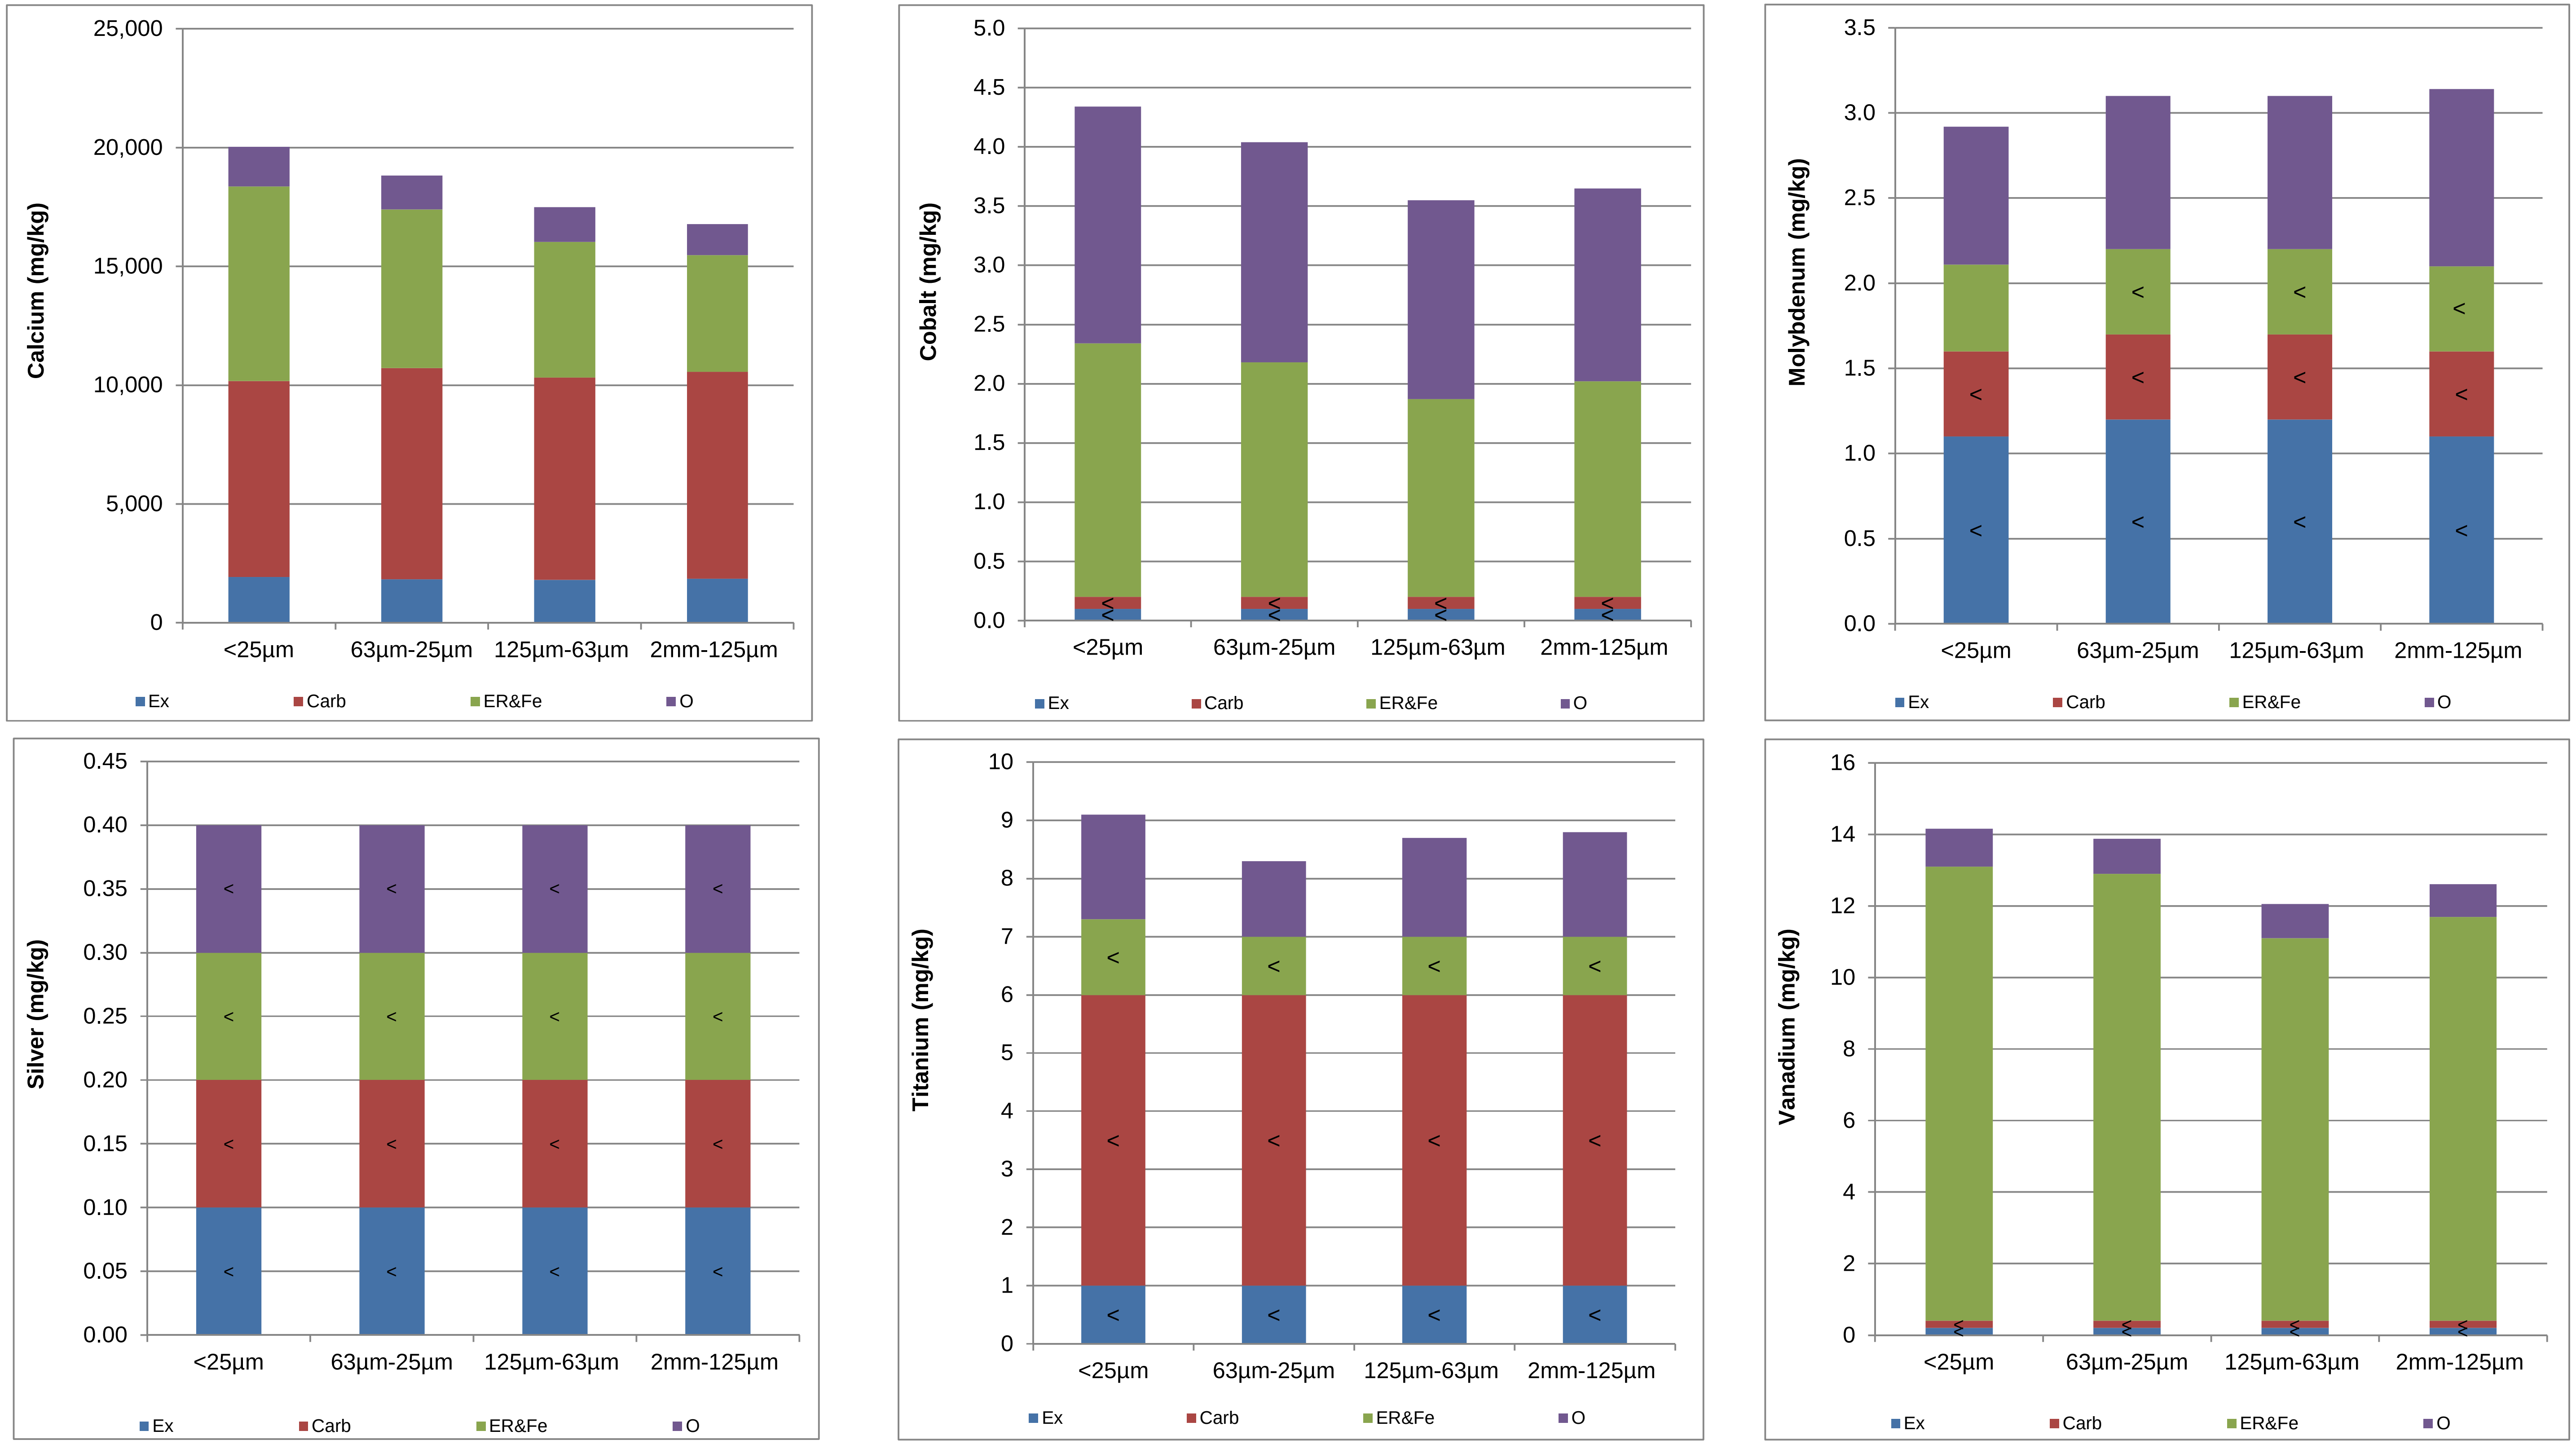

Figure E.7 (c): Concentrations of selectively extracted indicator parameters in Hazeltine Creek size-fractioned sediment sample HAC50, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) and Organic Bound Metals (O) fractions are shown (Residual metals are excluded).

Values < MDL are indicated with a < symbol. Data for boron were not available, sodium data were available only for the Ex fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result. Phosphorus data was only available for Ex, Carb, and ER&Fe fractions and was not plotted as a result.

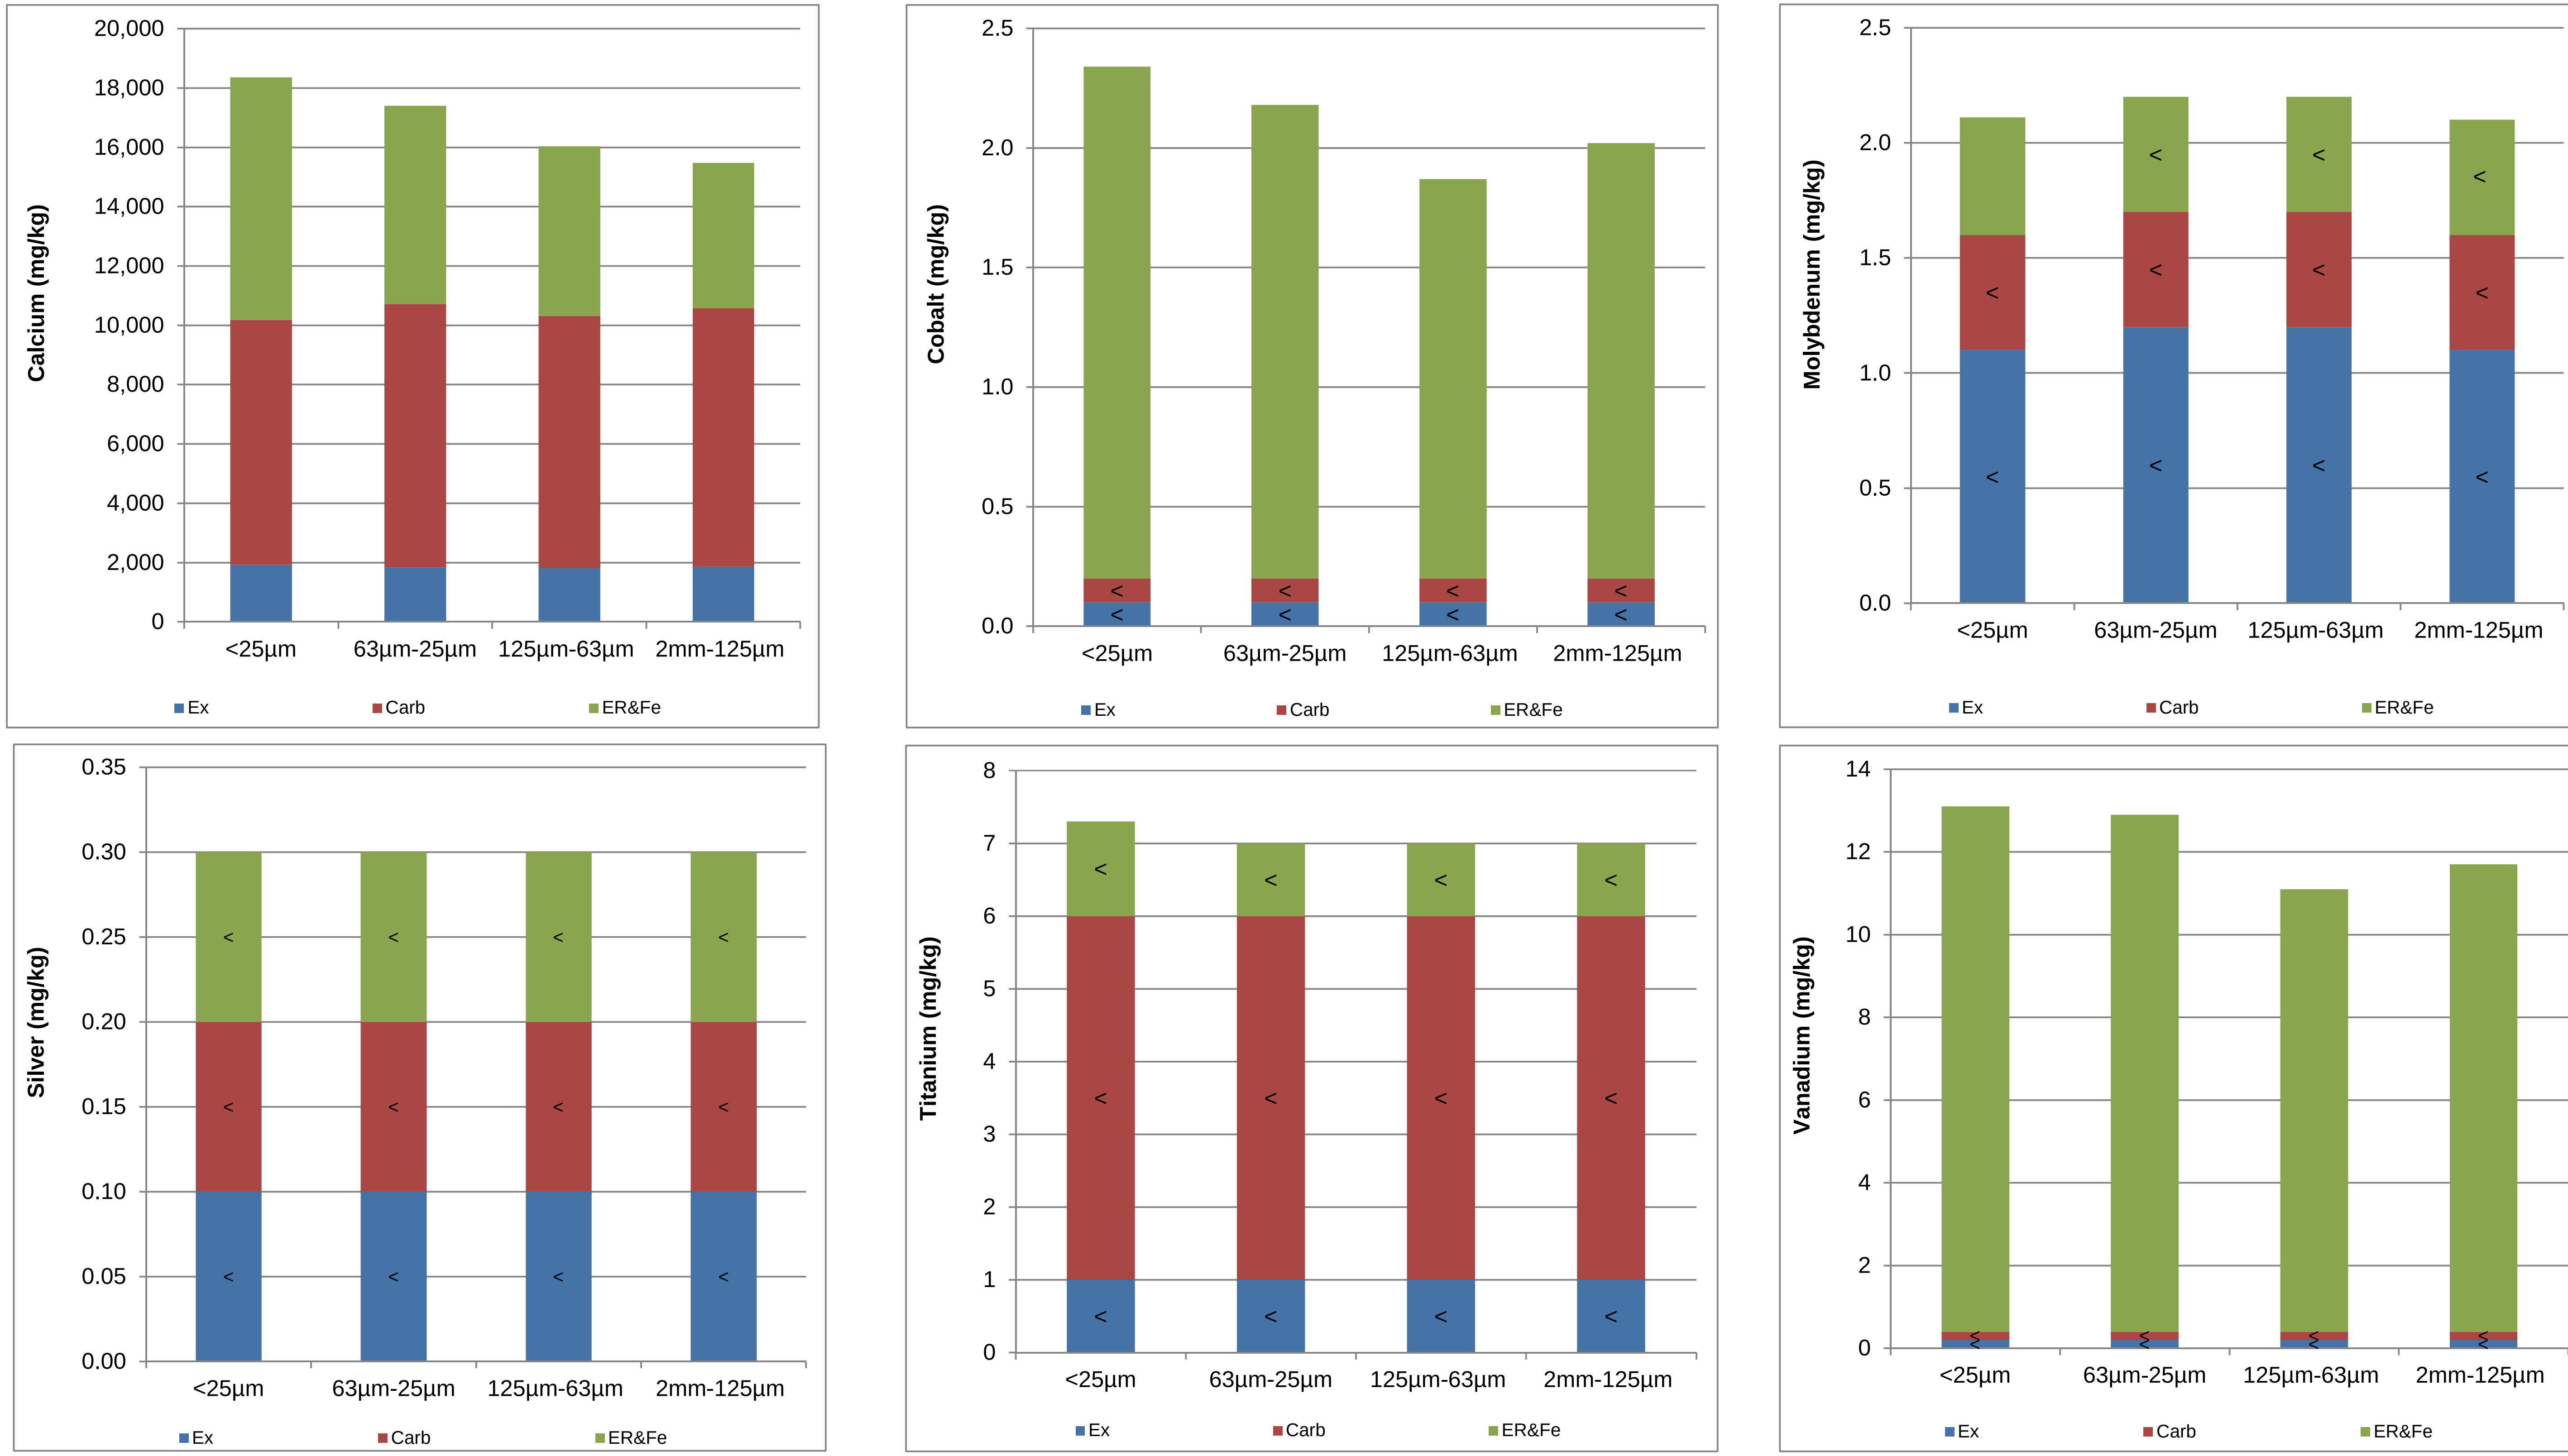

Figure E.7 (d): Concentrations of selectively extracted indicator parameters in Hazeltine Creek size-fractioned sediment sample HAC50, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) fractions are shown (Organic Bound and Residual metals are excluded).

Values < MDL are indicated with a < symbol. Data for boron were not available, sodium data were available only for the Ex fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result. Phosphorus data was only available for Ex, Carb, and ER&Fe fractions and was not plotted as a result.

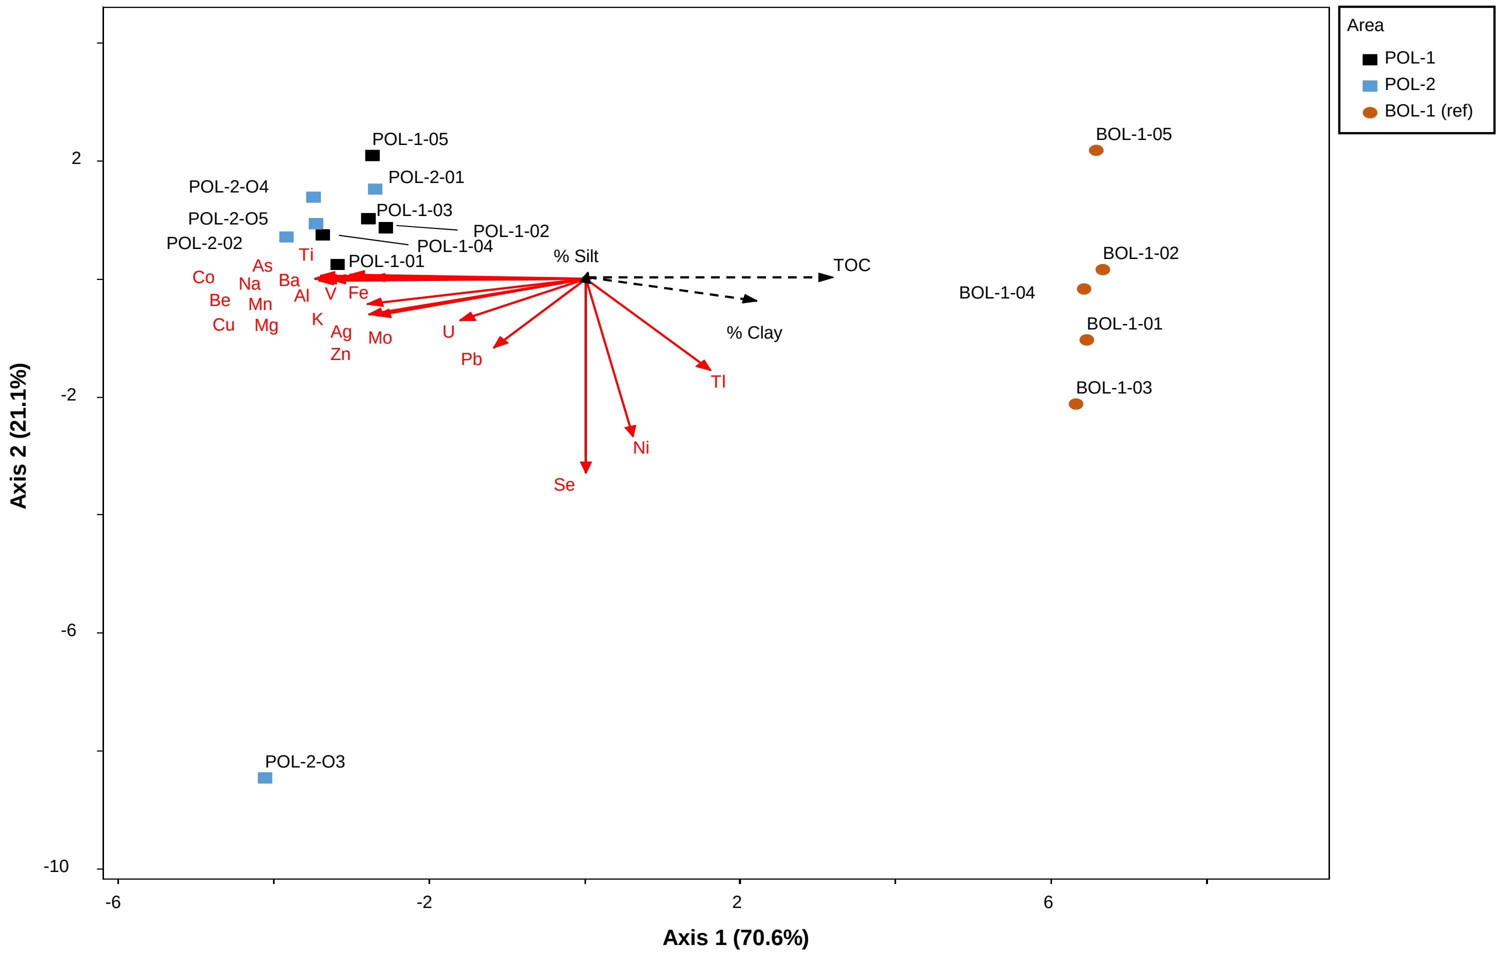

Figure E.8: Biplot of principal component analysis (PCA) of metal concentrations in sediment (<63 µm fraction) from Polley and Bootjack Lake mid-depth sampling stations, Mount Polley Mine, 2014. Vector length is proportional to the magnitude of direct correlation of metals (solid red vector lines) and indirect correlation of sediment physical characteristics (black dashed vector lines) with PCA values of each axis (Appendix Tables E.27-E.28). Only metals with significant (p-value <0.010) Spearman's correlation and r-values > 0.7 with either axis are displayed, all sediment physical characteristics are displayed.

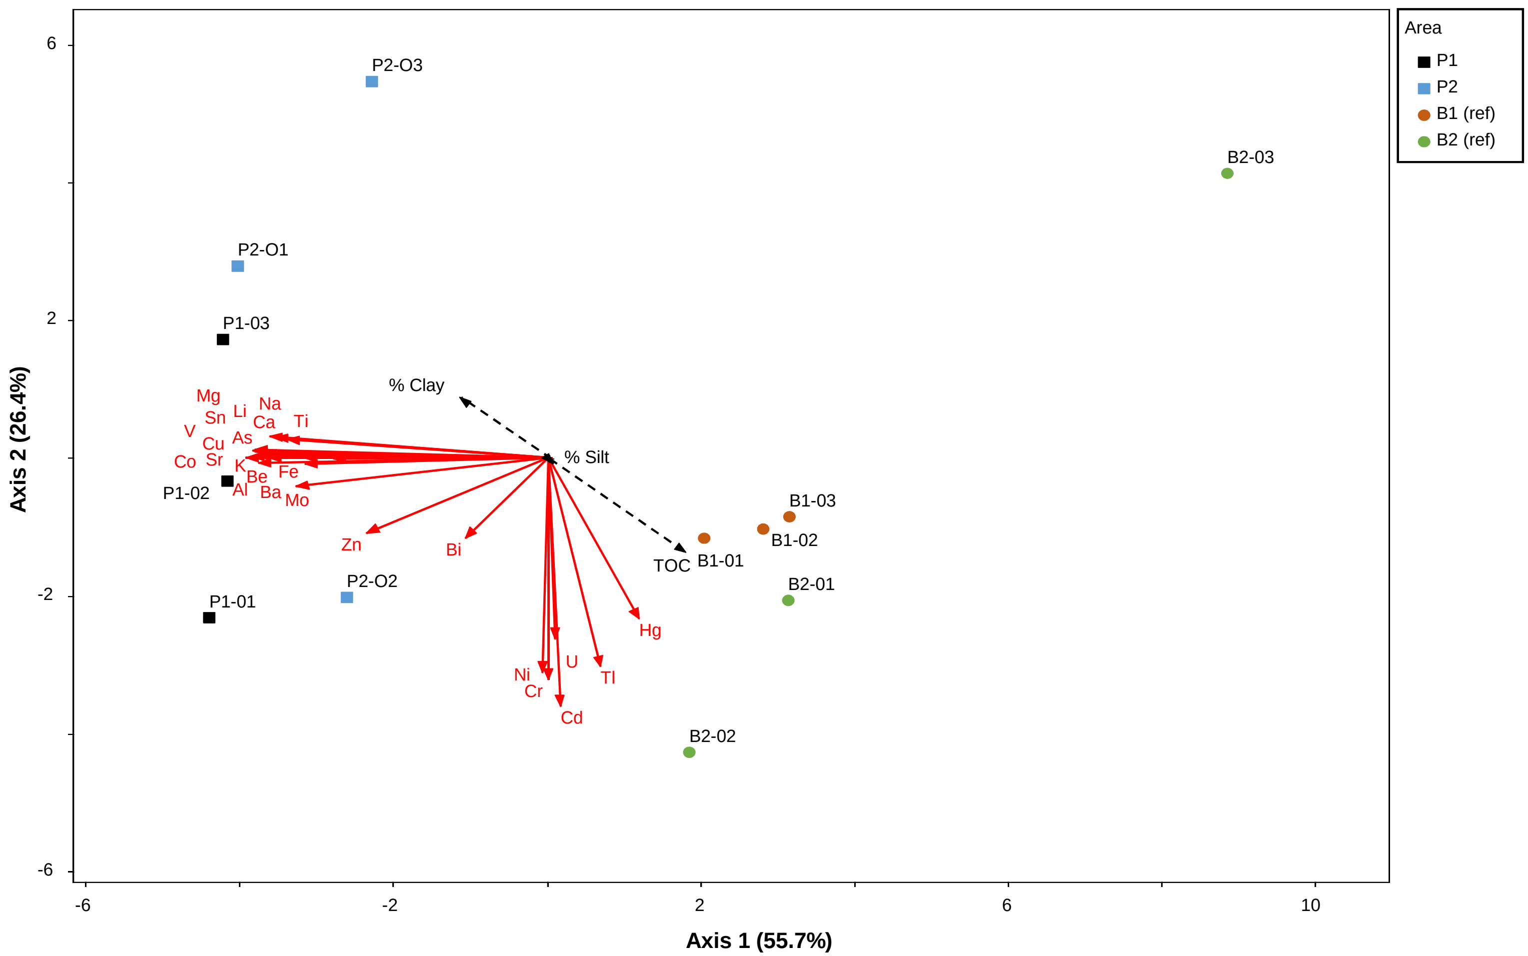

Figure E.9: **Biplot of principal component analysis (PCA) of metal concentrations in sediment (<63 µm fraction) from Polley and Bootjack Lake deep sampling stations, Mount Polley Mine, 2014. Vector length is proportional to the magnitude of direct correlation of metals (solid red vector lines) and indirect correlation of sediment physical characteristics (black dashed vector lines) with PCA values of each axis (Appendix Tables E.29-E.30). Only metals with significant (p-value <0.010) Spearman's correlation and r-values > 0.7 with either axis are displayed, all sediment physical characteristics are displayed**

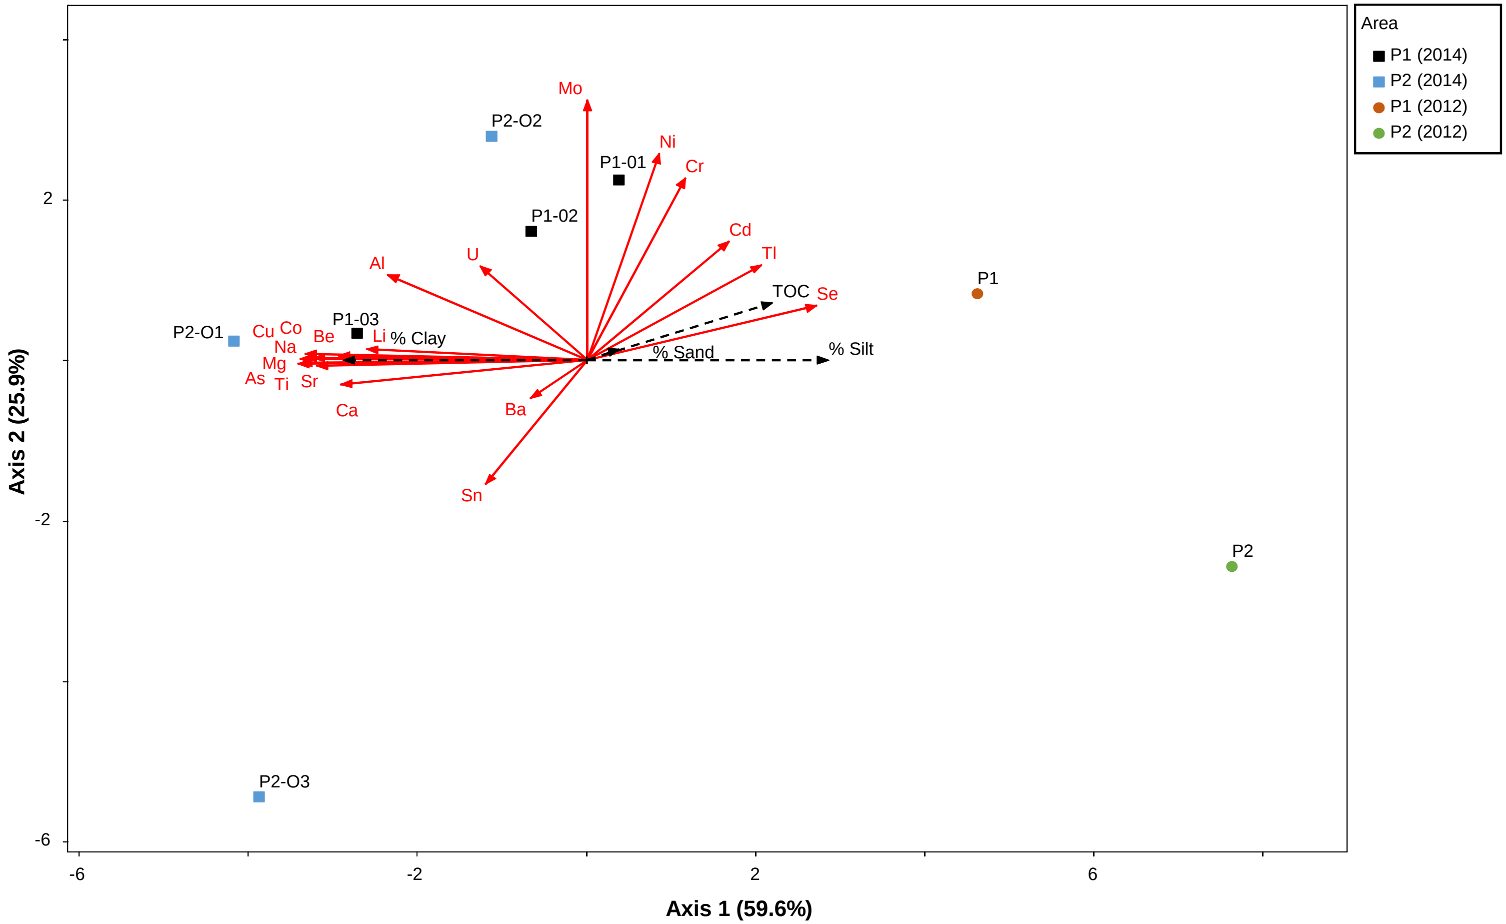

Figure E.10: Biplot of principal component analysis (PCA) of metal concentrations in sediment from Polley Lake deep sampling stations in 2014 (<2mm fraction) and in 2012 (bulk sediment), Mount Polley Mine, 2014. Vector length is proportional to the magnitude of direct correlation of metals (solid red vector lines) and indirect correlation of sediment physical characteristics (black dashed vector lines) with PCA values of each axis (Appendix Tables E.31-E.32). Only metals with significant (p-value <0.010) Spearman's correlation and r-values > 0.7 with either axis are displayed, all sediment physical characteristics are displayed [a]

[a] Bismuth, boron, and mercury were excluded from calculations due to a lack of variability in the data (all values for each analyte were the same), or an incomplete data set among years.

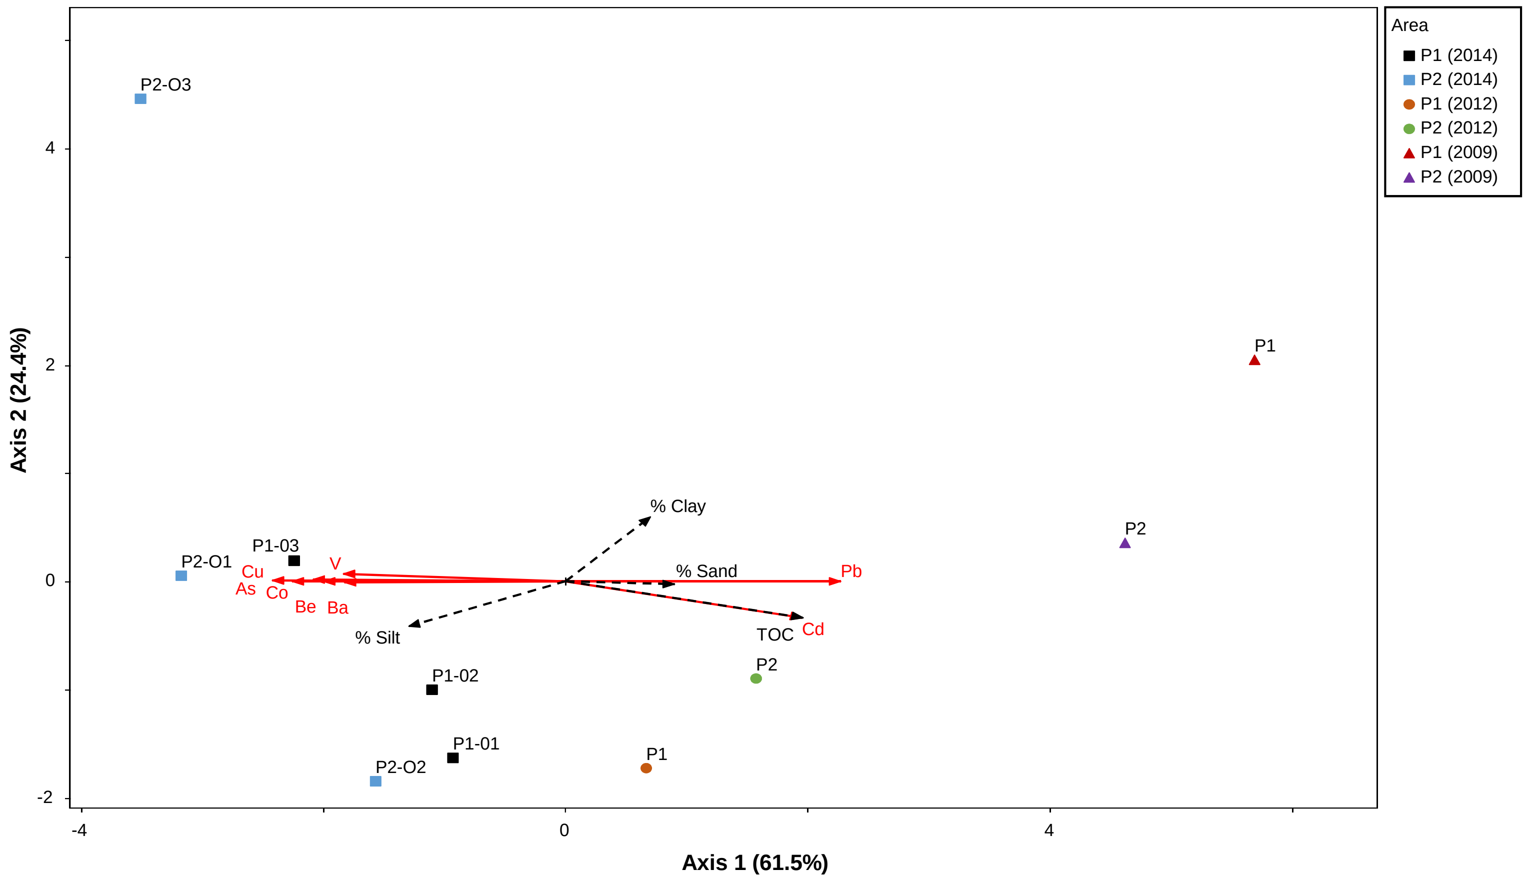

Figure E.11: Biplot of principal component analysis (PCA) of metal concentrations in sediment from Polley Lake deep sampling stations in 2014 (<2mm fraction) and in 2012 and in 2009 (bulk sediment), Mount Polley Mine, 2014. Vector length is proportional to the magnitude of direct correlation of metals (solid red vector lines) and indirect correlation of sediment physical characteristics (black dashed vector lines) with PCA values of each axis (Appendix Tables E.33-E.34). Only metals with significant (p-value <0.010) Spearman's correlation and r-values > 0.7 with either axis are displayed, all sediment physical characteristics are displayed [a].

[a] Aluminum, bismuth, boron, calcium, iron, lithium, mercury, magnesium, manganese, phosphorus, potassium, sodium, strontium, thallium, titanium, and uranium were excluded from calculations due to a lack of variability in the data (all values for each analyte were the same), or an incomplete data set among years.

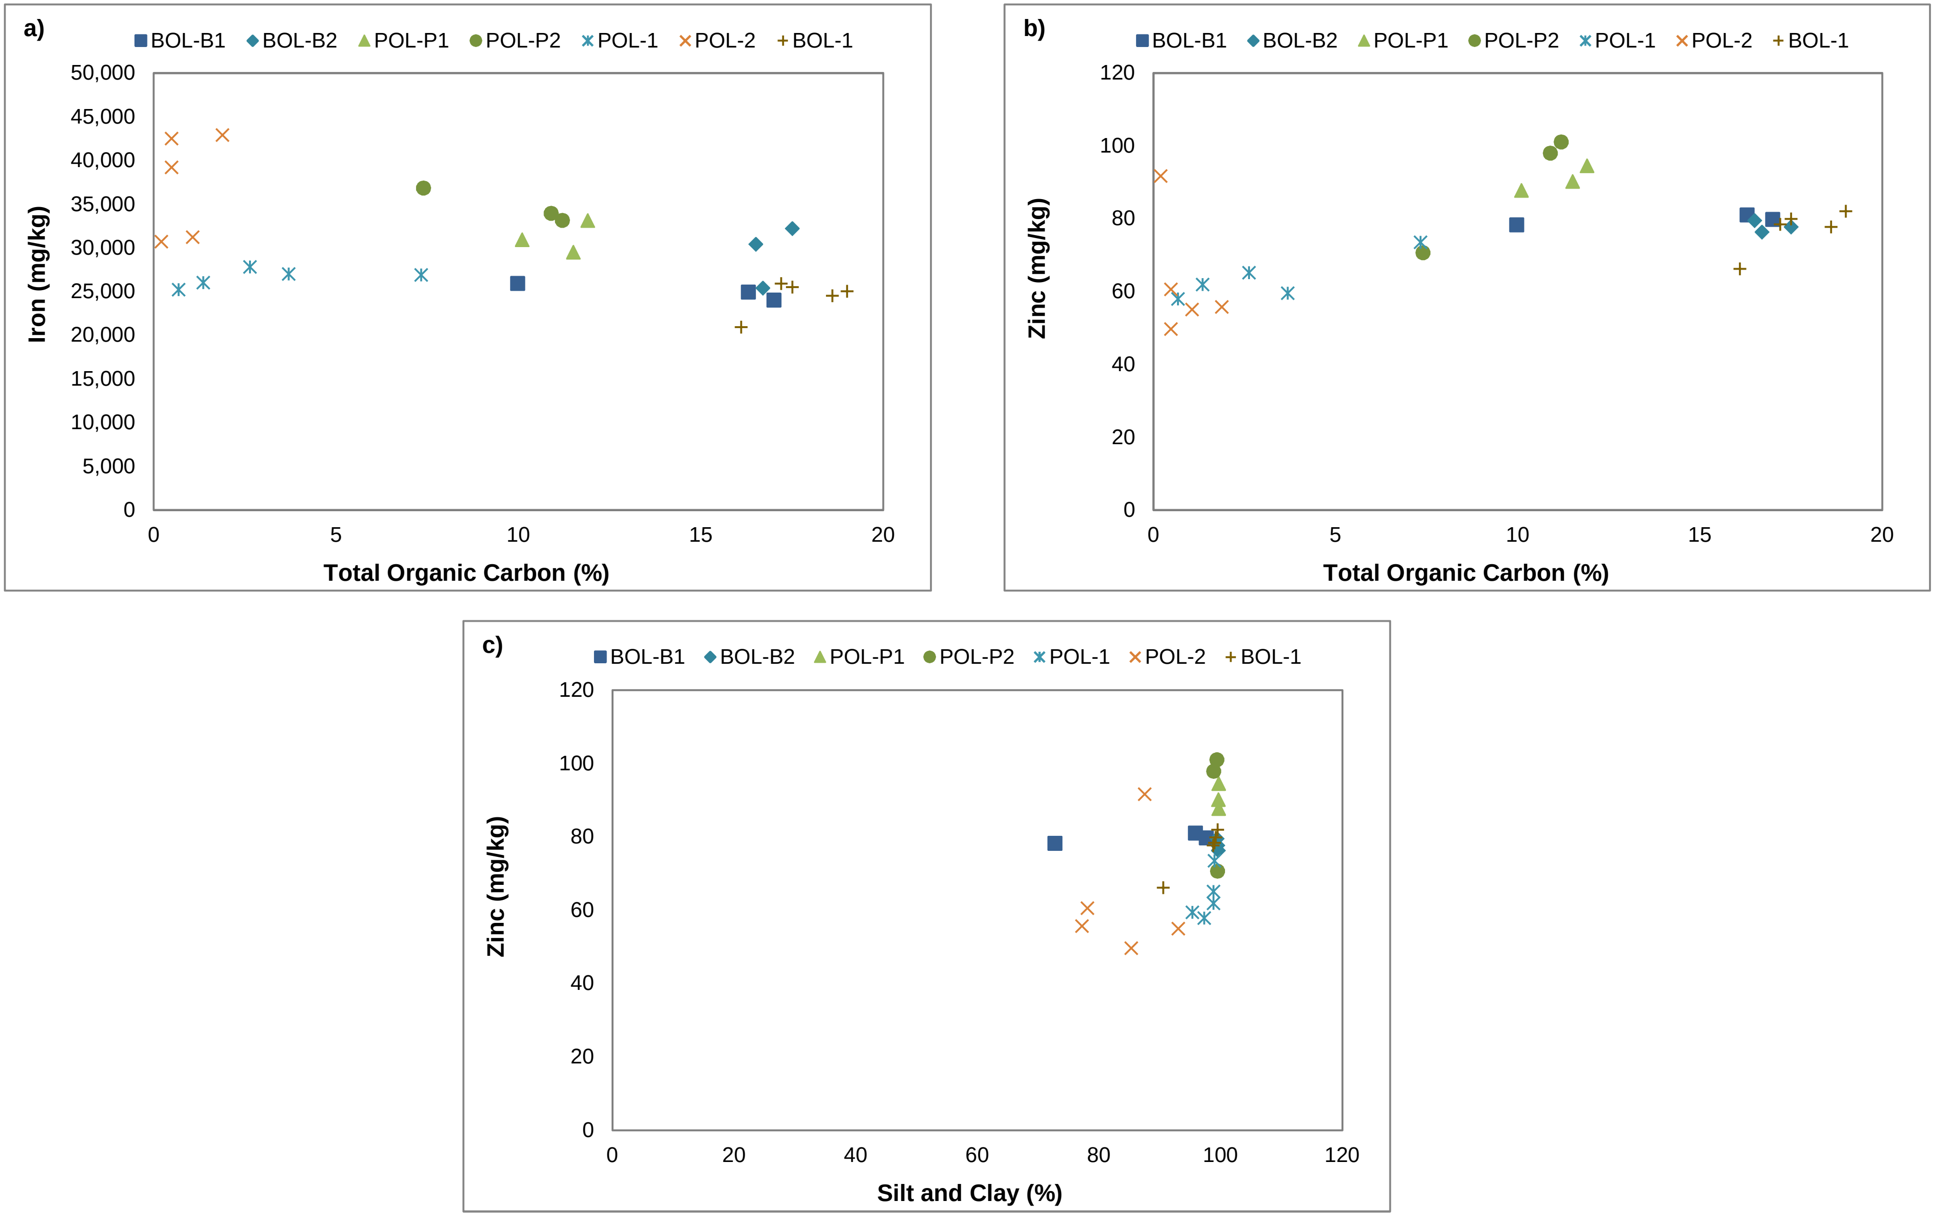

Figure E.12: Scatterplots of Spearman's correlation relationships ($p < 0.01$) between total organic carbon (%) or silt and clay (%) and parameters of interest, Mount Polley Study 2014. Polley and Bootjack Lake mid-depth and basin sampling areas.

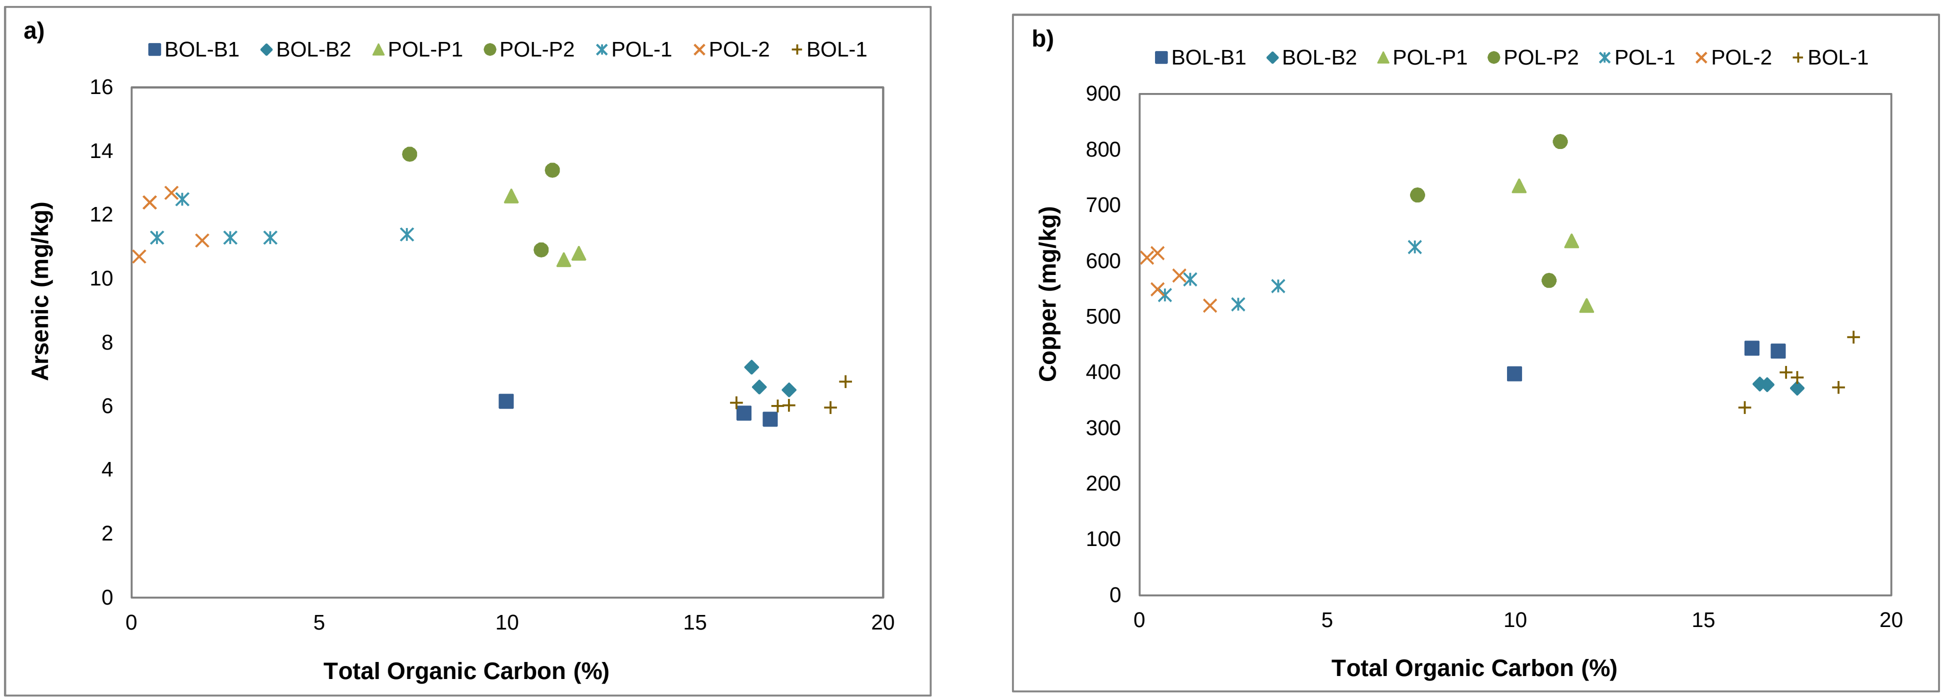

Figure E.13: Scatterplots of significant Spearman's correlation relationships (p<0.003) between total organic carbon (%) and parameters of interest, Polley and Bootjack Lake mid-depth and basin sampling areas, Mount Polley Mine, 2014.

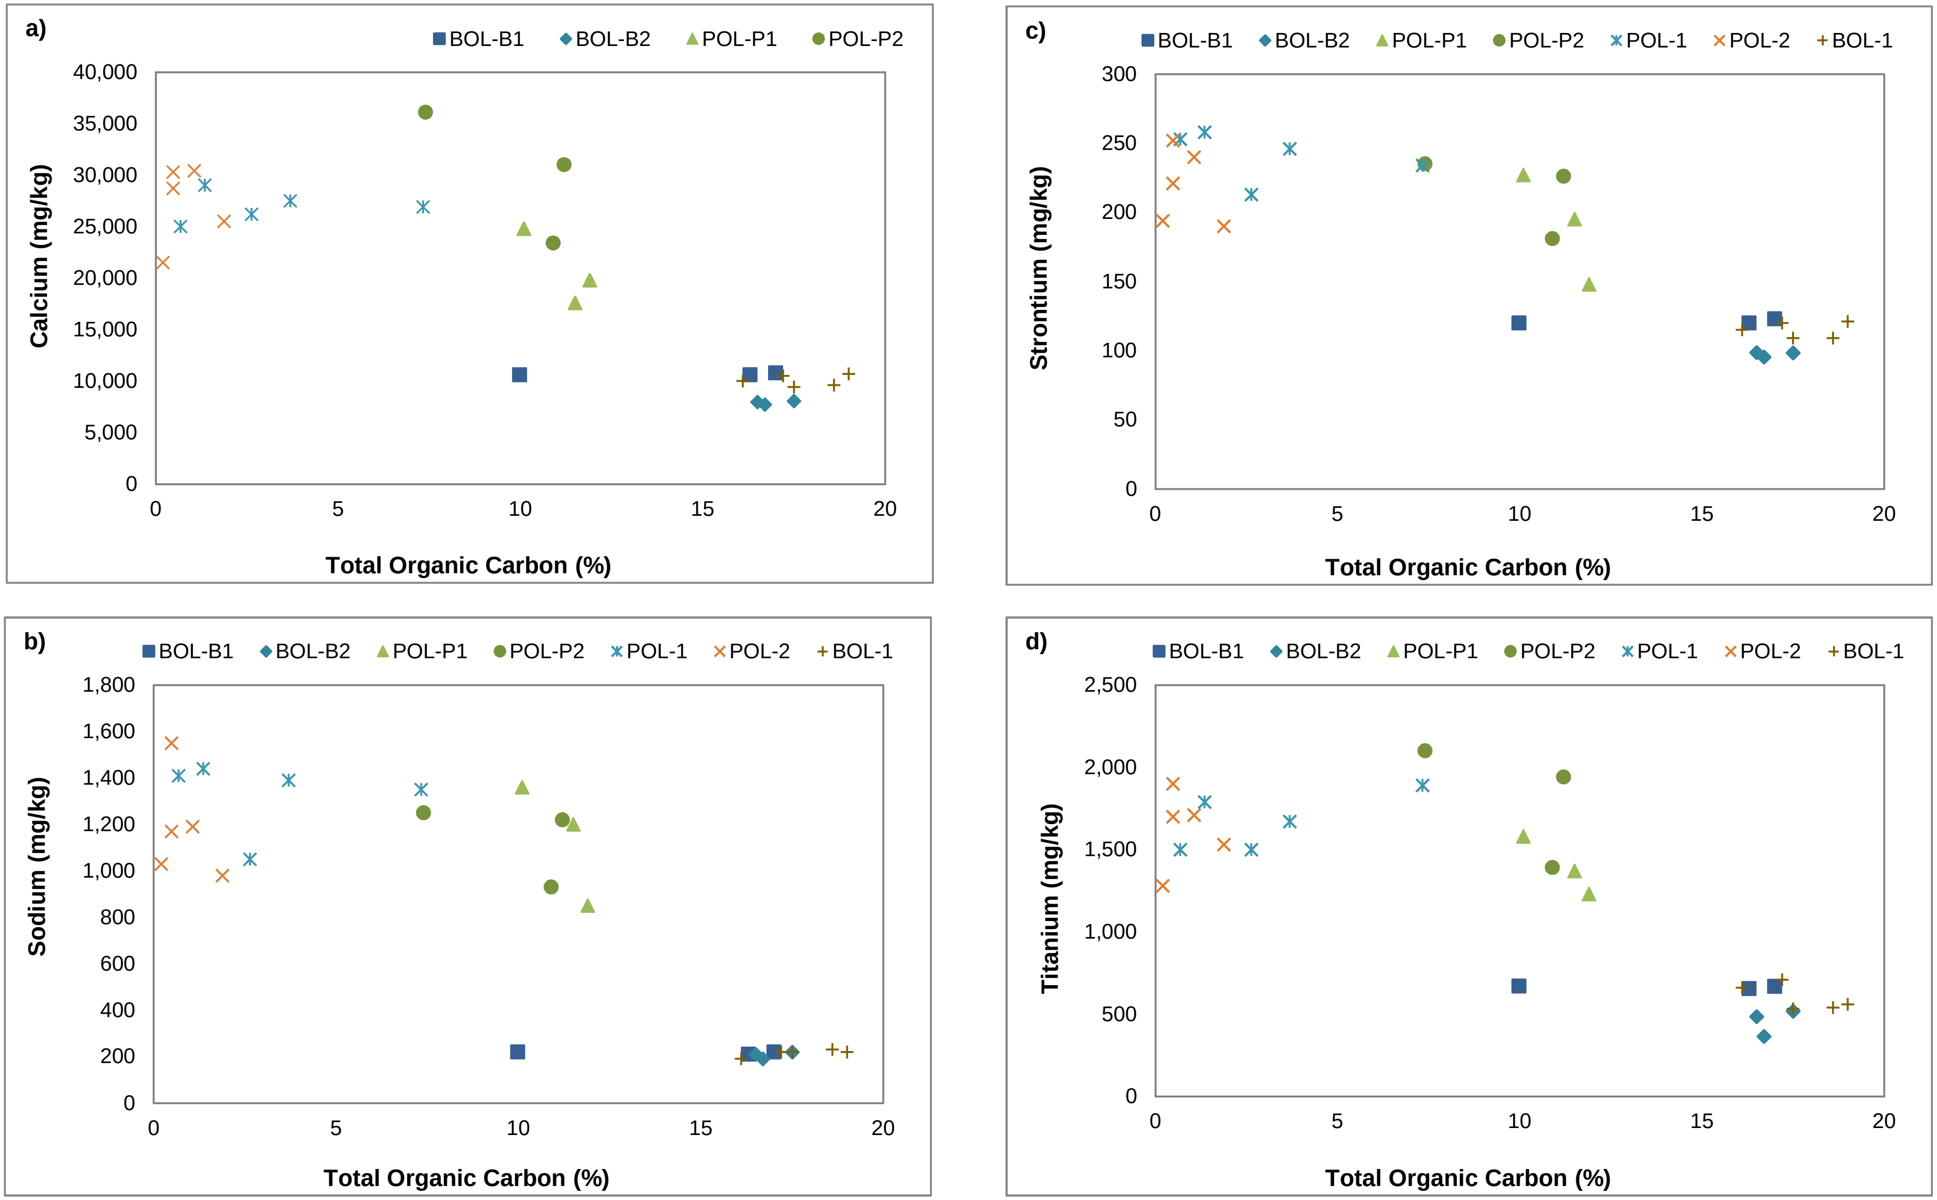

Figure E.14: Scatterplots of significant Spearman's correlation relationships ($p < 0.003$) between total organic carbon (%) and indicator parameters, Polley and Bootjack Lake mid-depth and basin sampling areas, Mount Polley Mine, 2014.

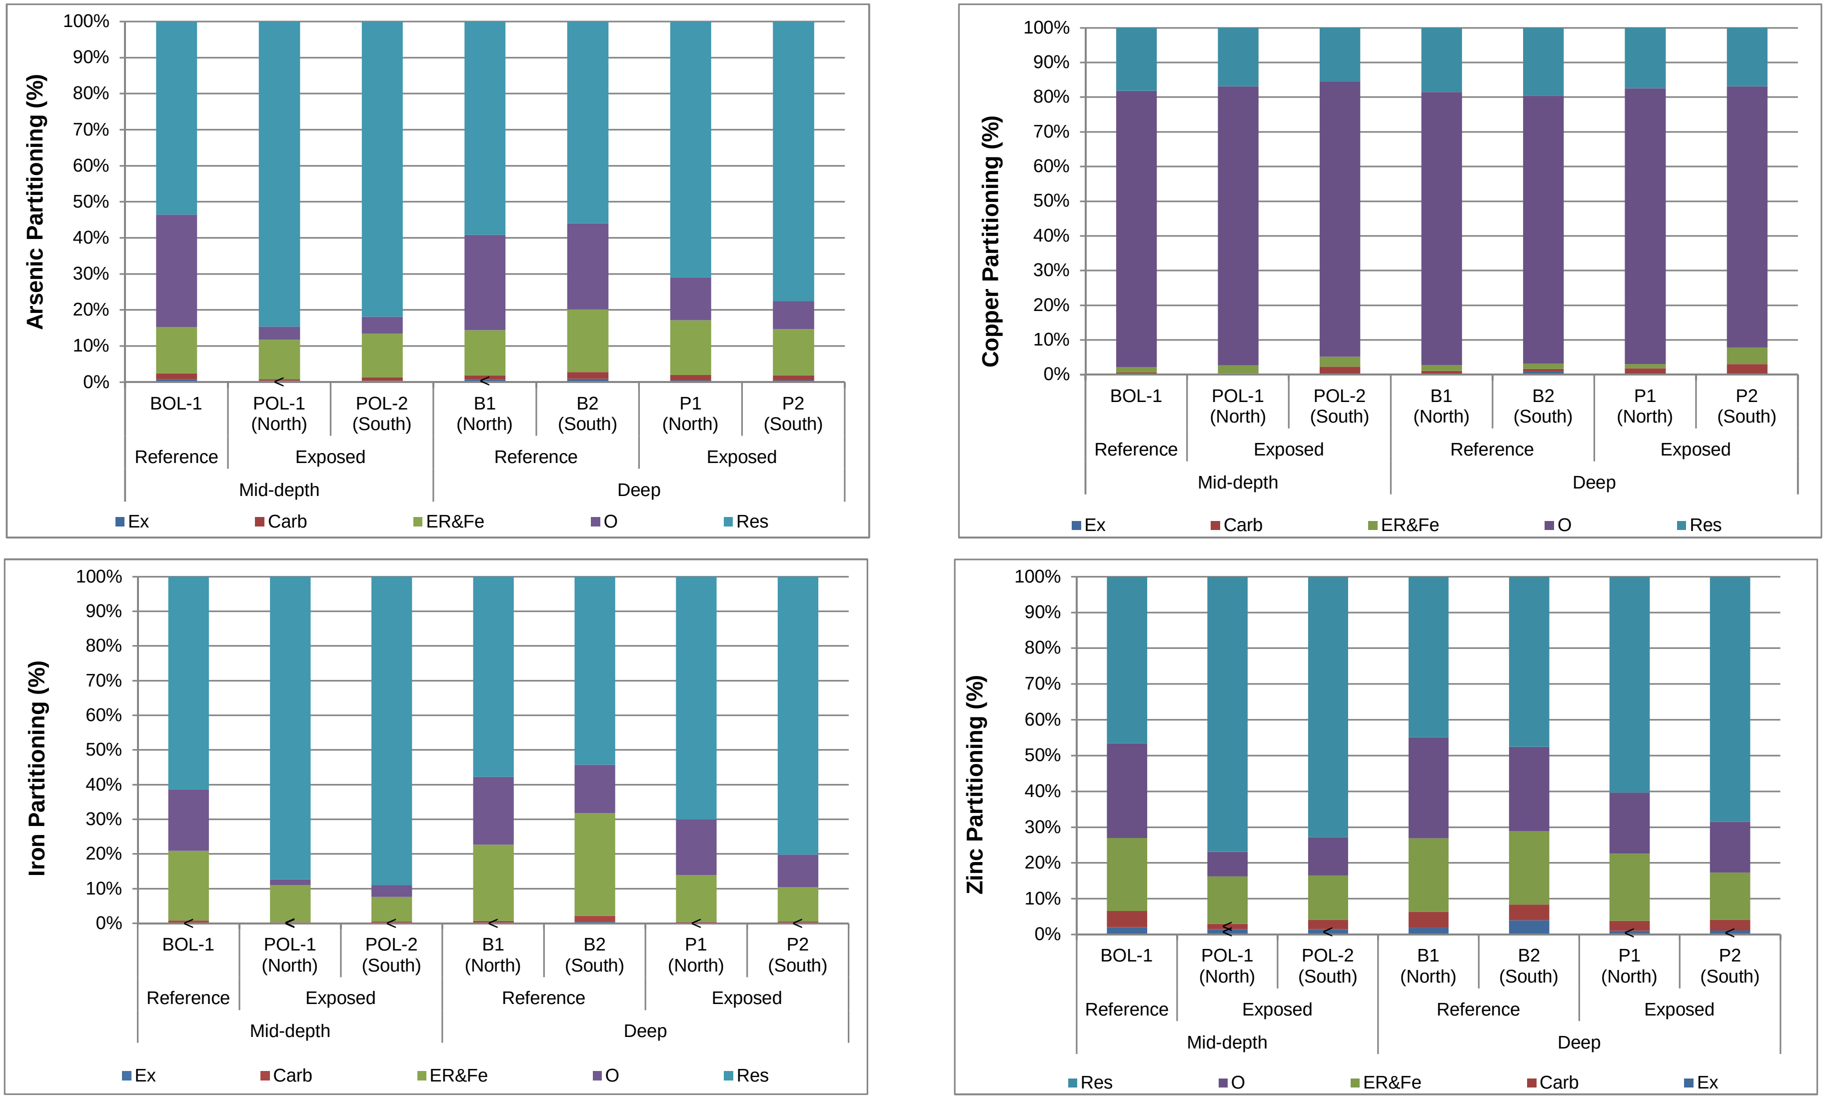

Figure E.15 (a): Partitioning of selectively extracted parameters of interest in sediment from mid-depth and deep sampling areas of Polley Lake, Mount Polley Mine, 2014. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic Bound Metals (O), and Residual Metals (Res).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL.

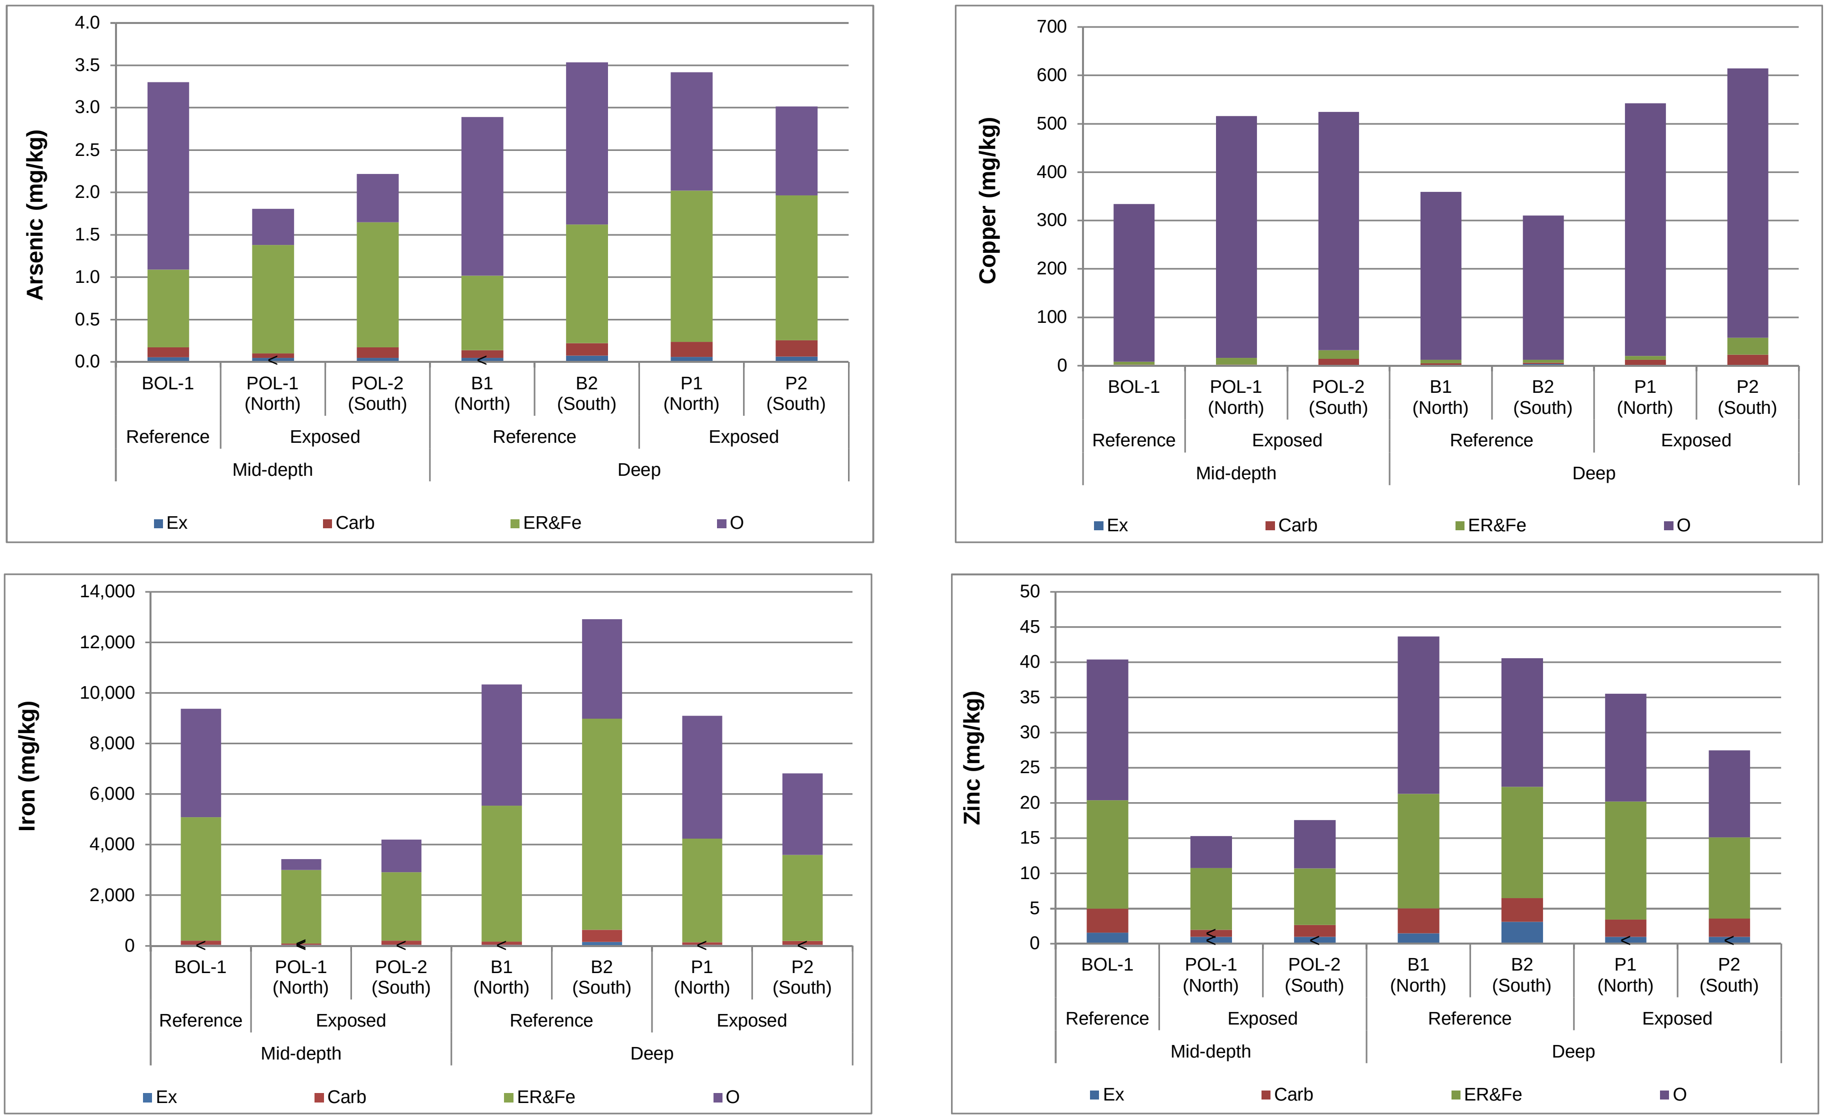

Figure E.15 (b): Mean concentrations of selectively extracted parameters of interest in sediment from mid-depth and deep sampling areas of Polley Lake, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) and Organic Bound Metals (O) fractions are shown (Residual metals are excluded).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL.

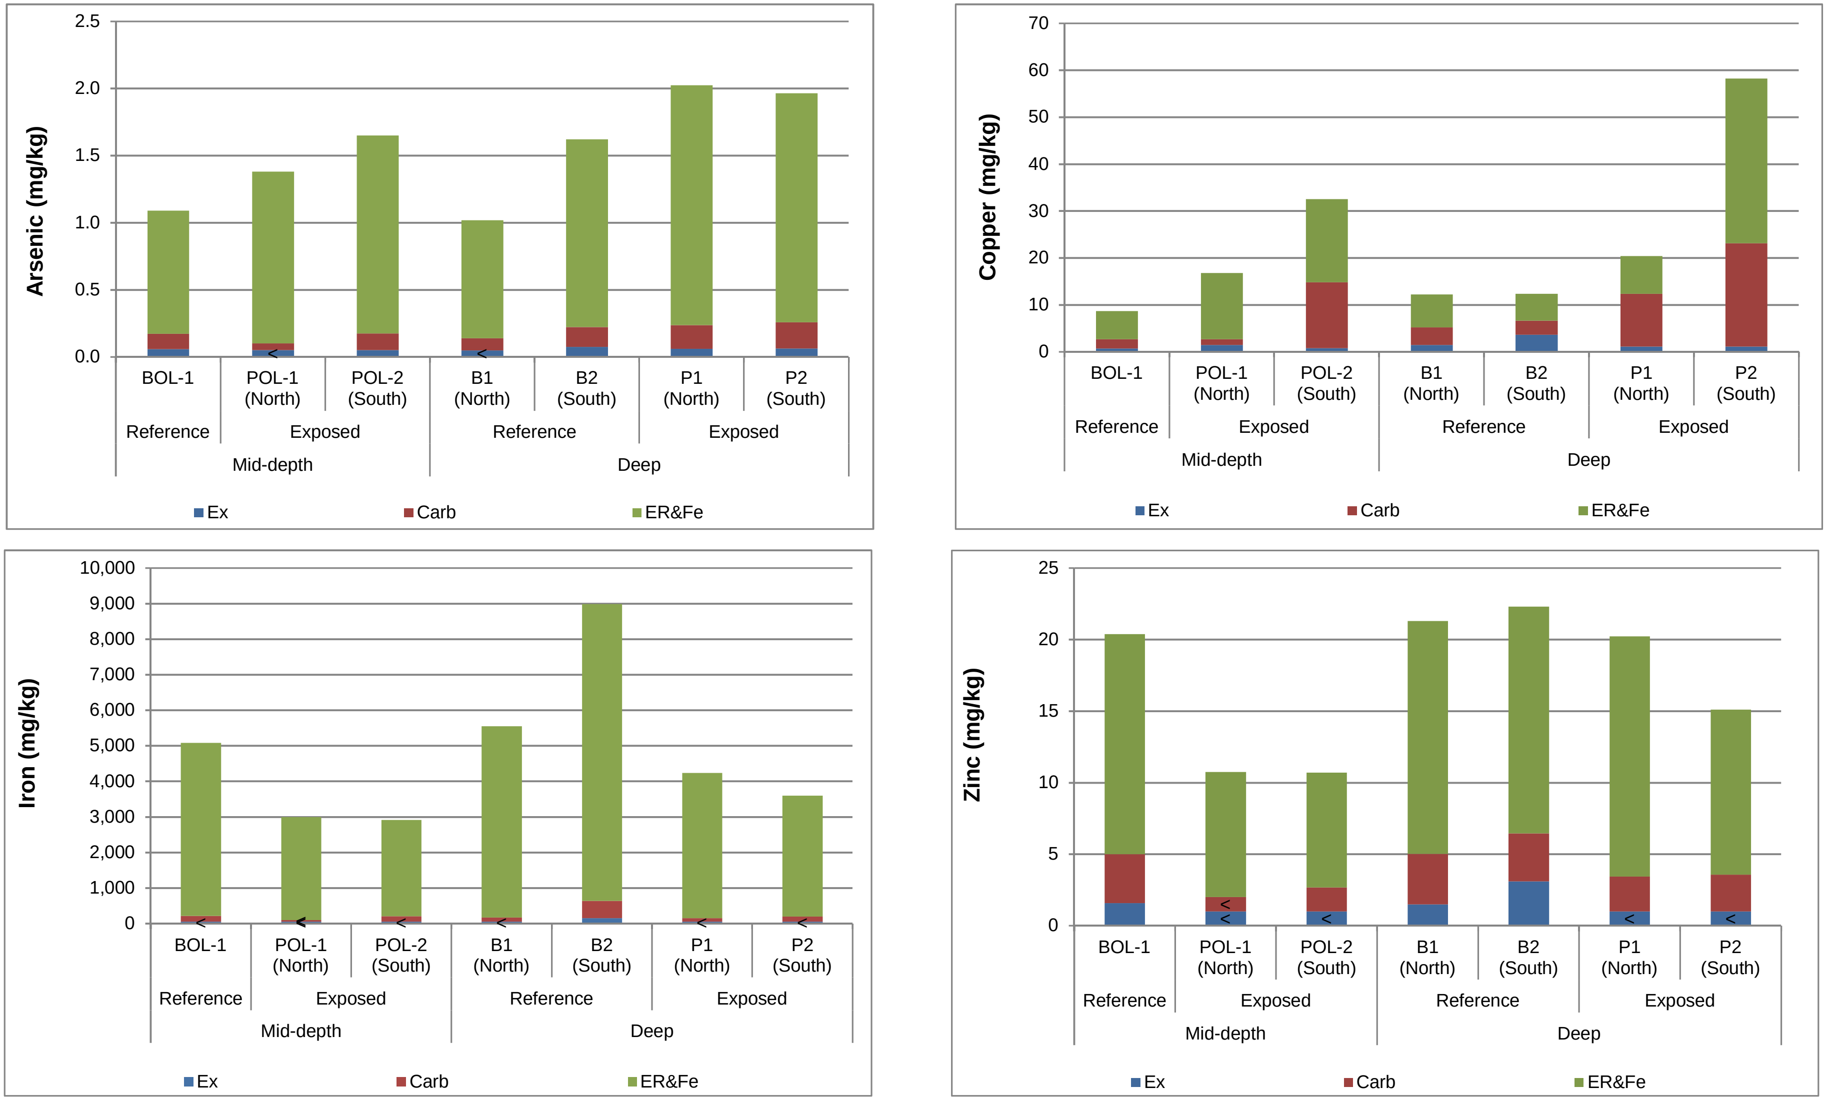

Figure E.15 (c): Mean concentrations of selectively extracted parameters of interest in sediment from mid-depth and deep sampling areas of Polley Lake, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) fractions are shown (Organic Bound and Residual metals are excluded).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL.

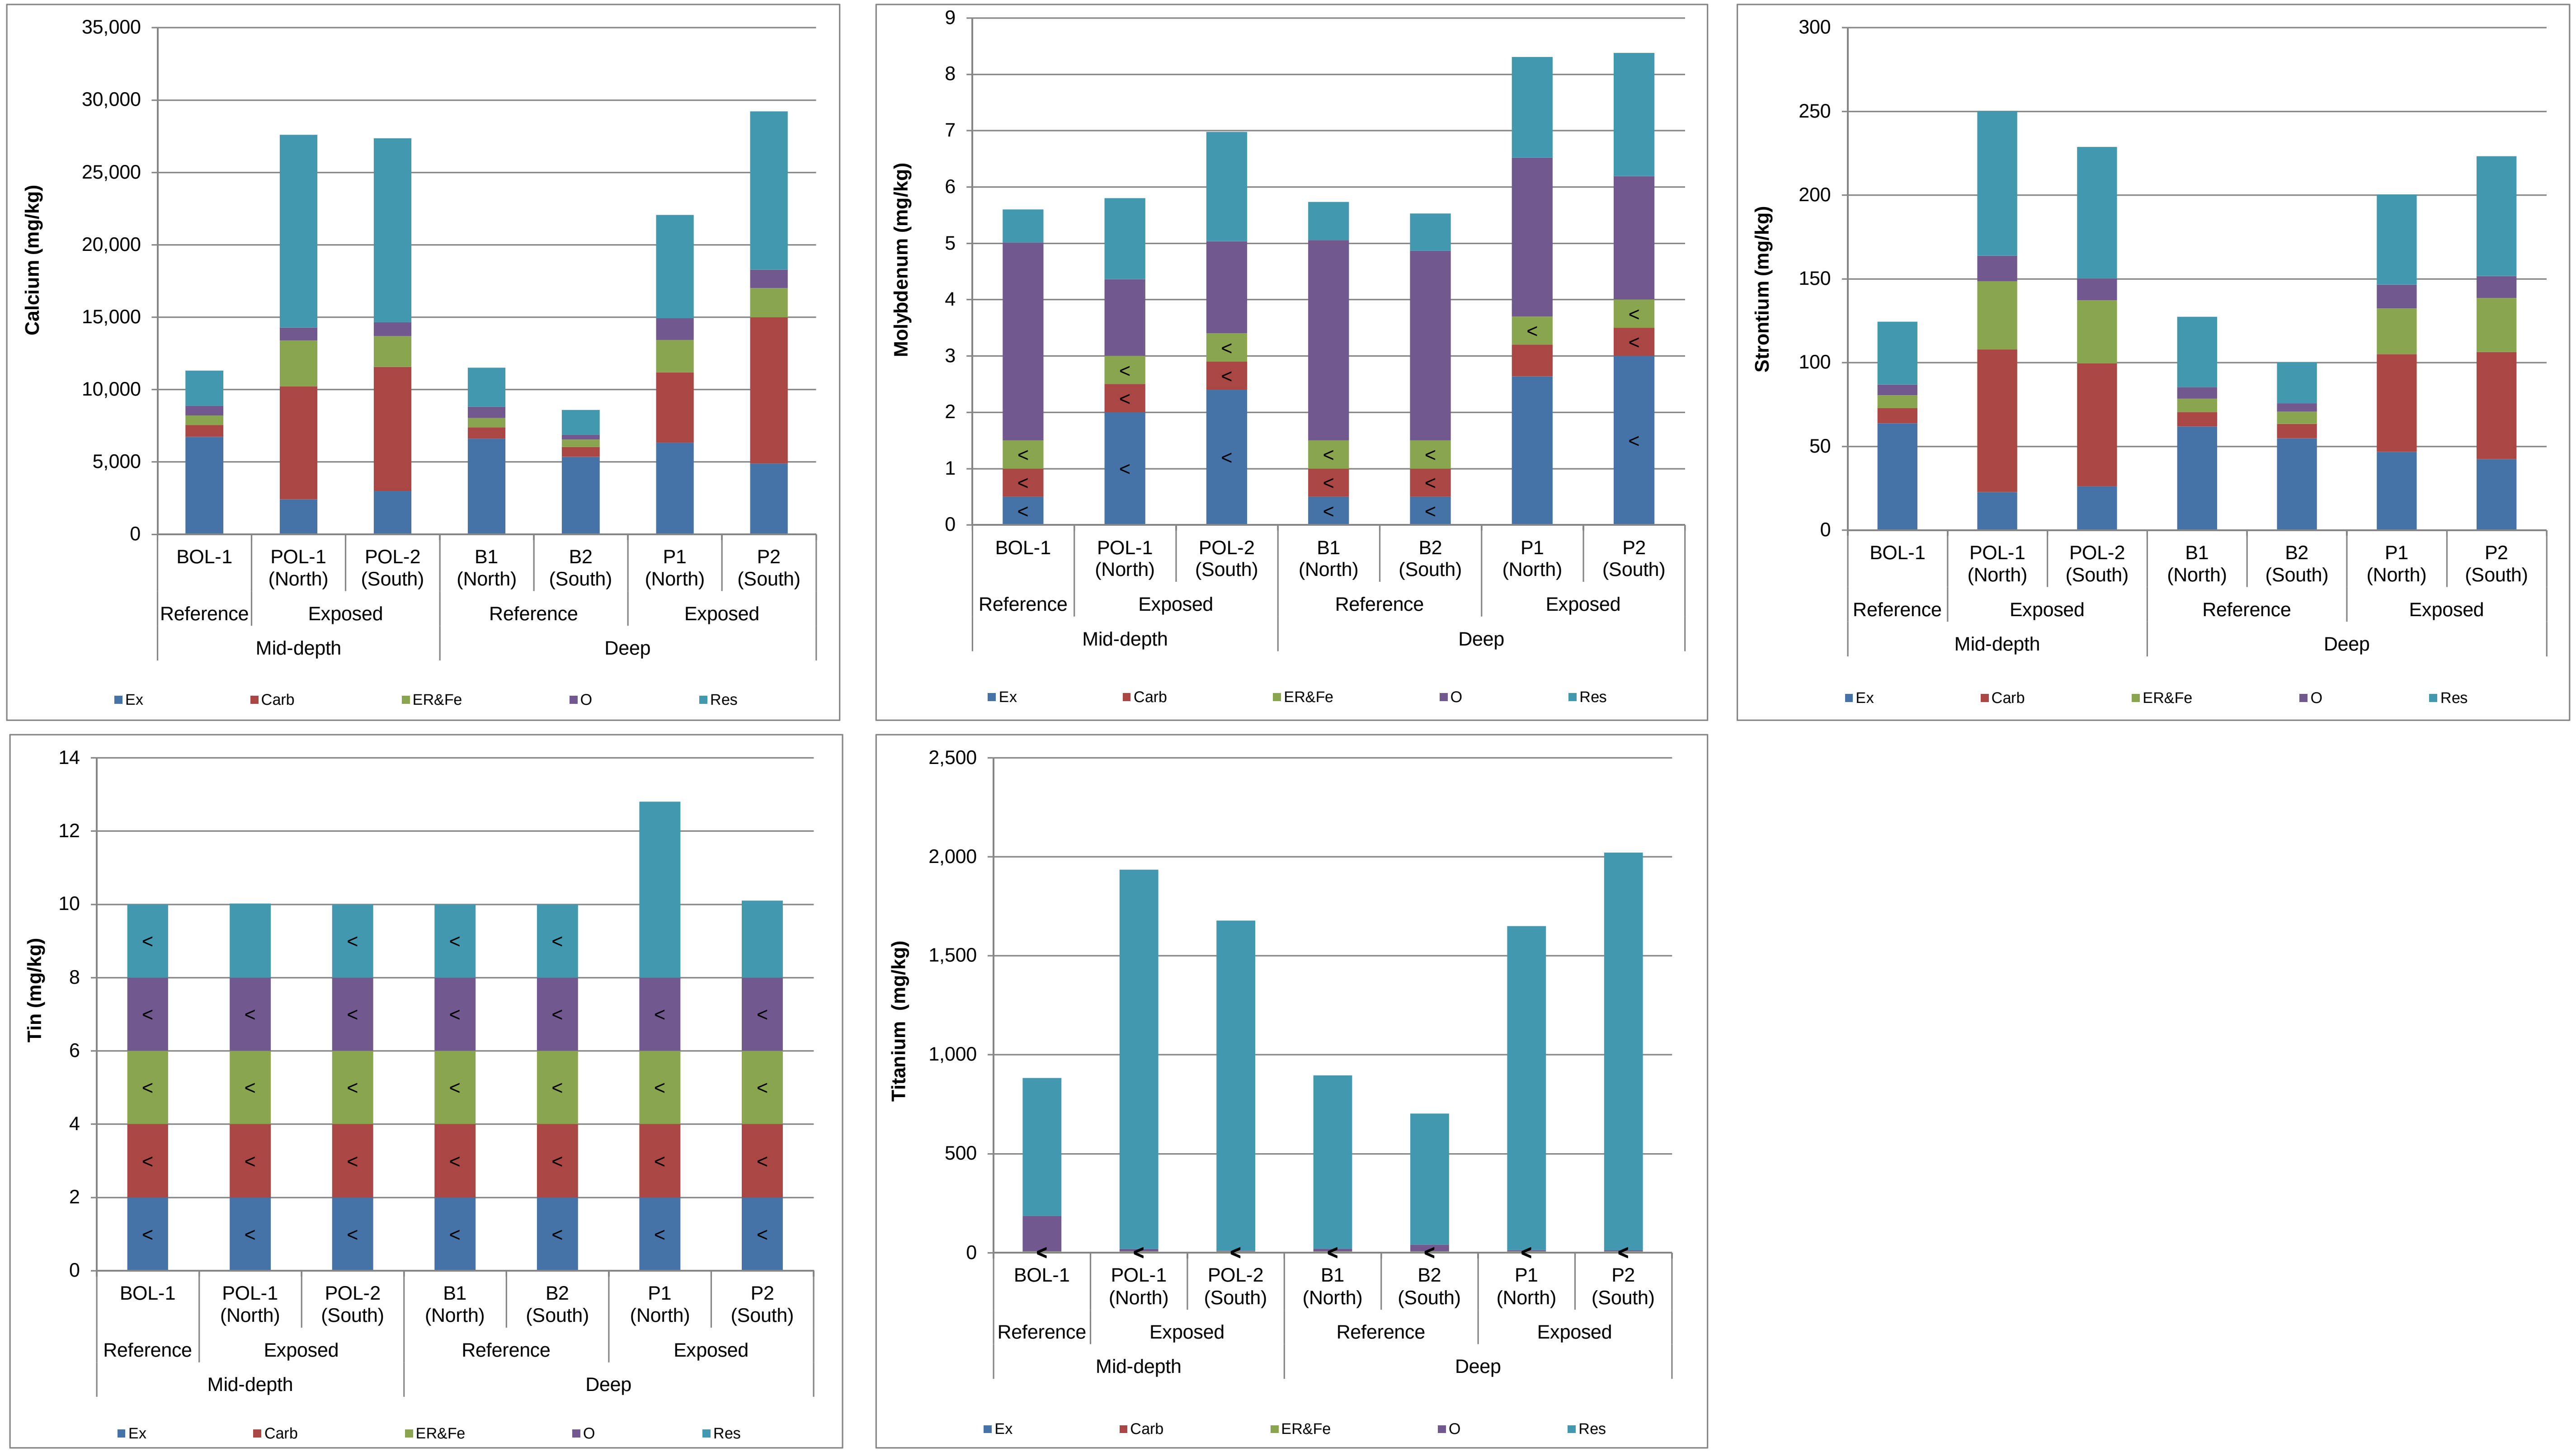

Figure E.16 (a): Mean concentrations of selectively extracted indicator parameters in sediment from mid-depth and deep sampling areas of Polley Lake, Mount Polley Mine, 2014. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic Bound Metals (O), and Residual Metals (Res).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL. Sodium data were available only for the Exchangeable & Adsorbed Metals fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result.

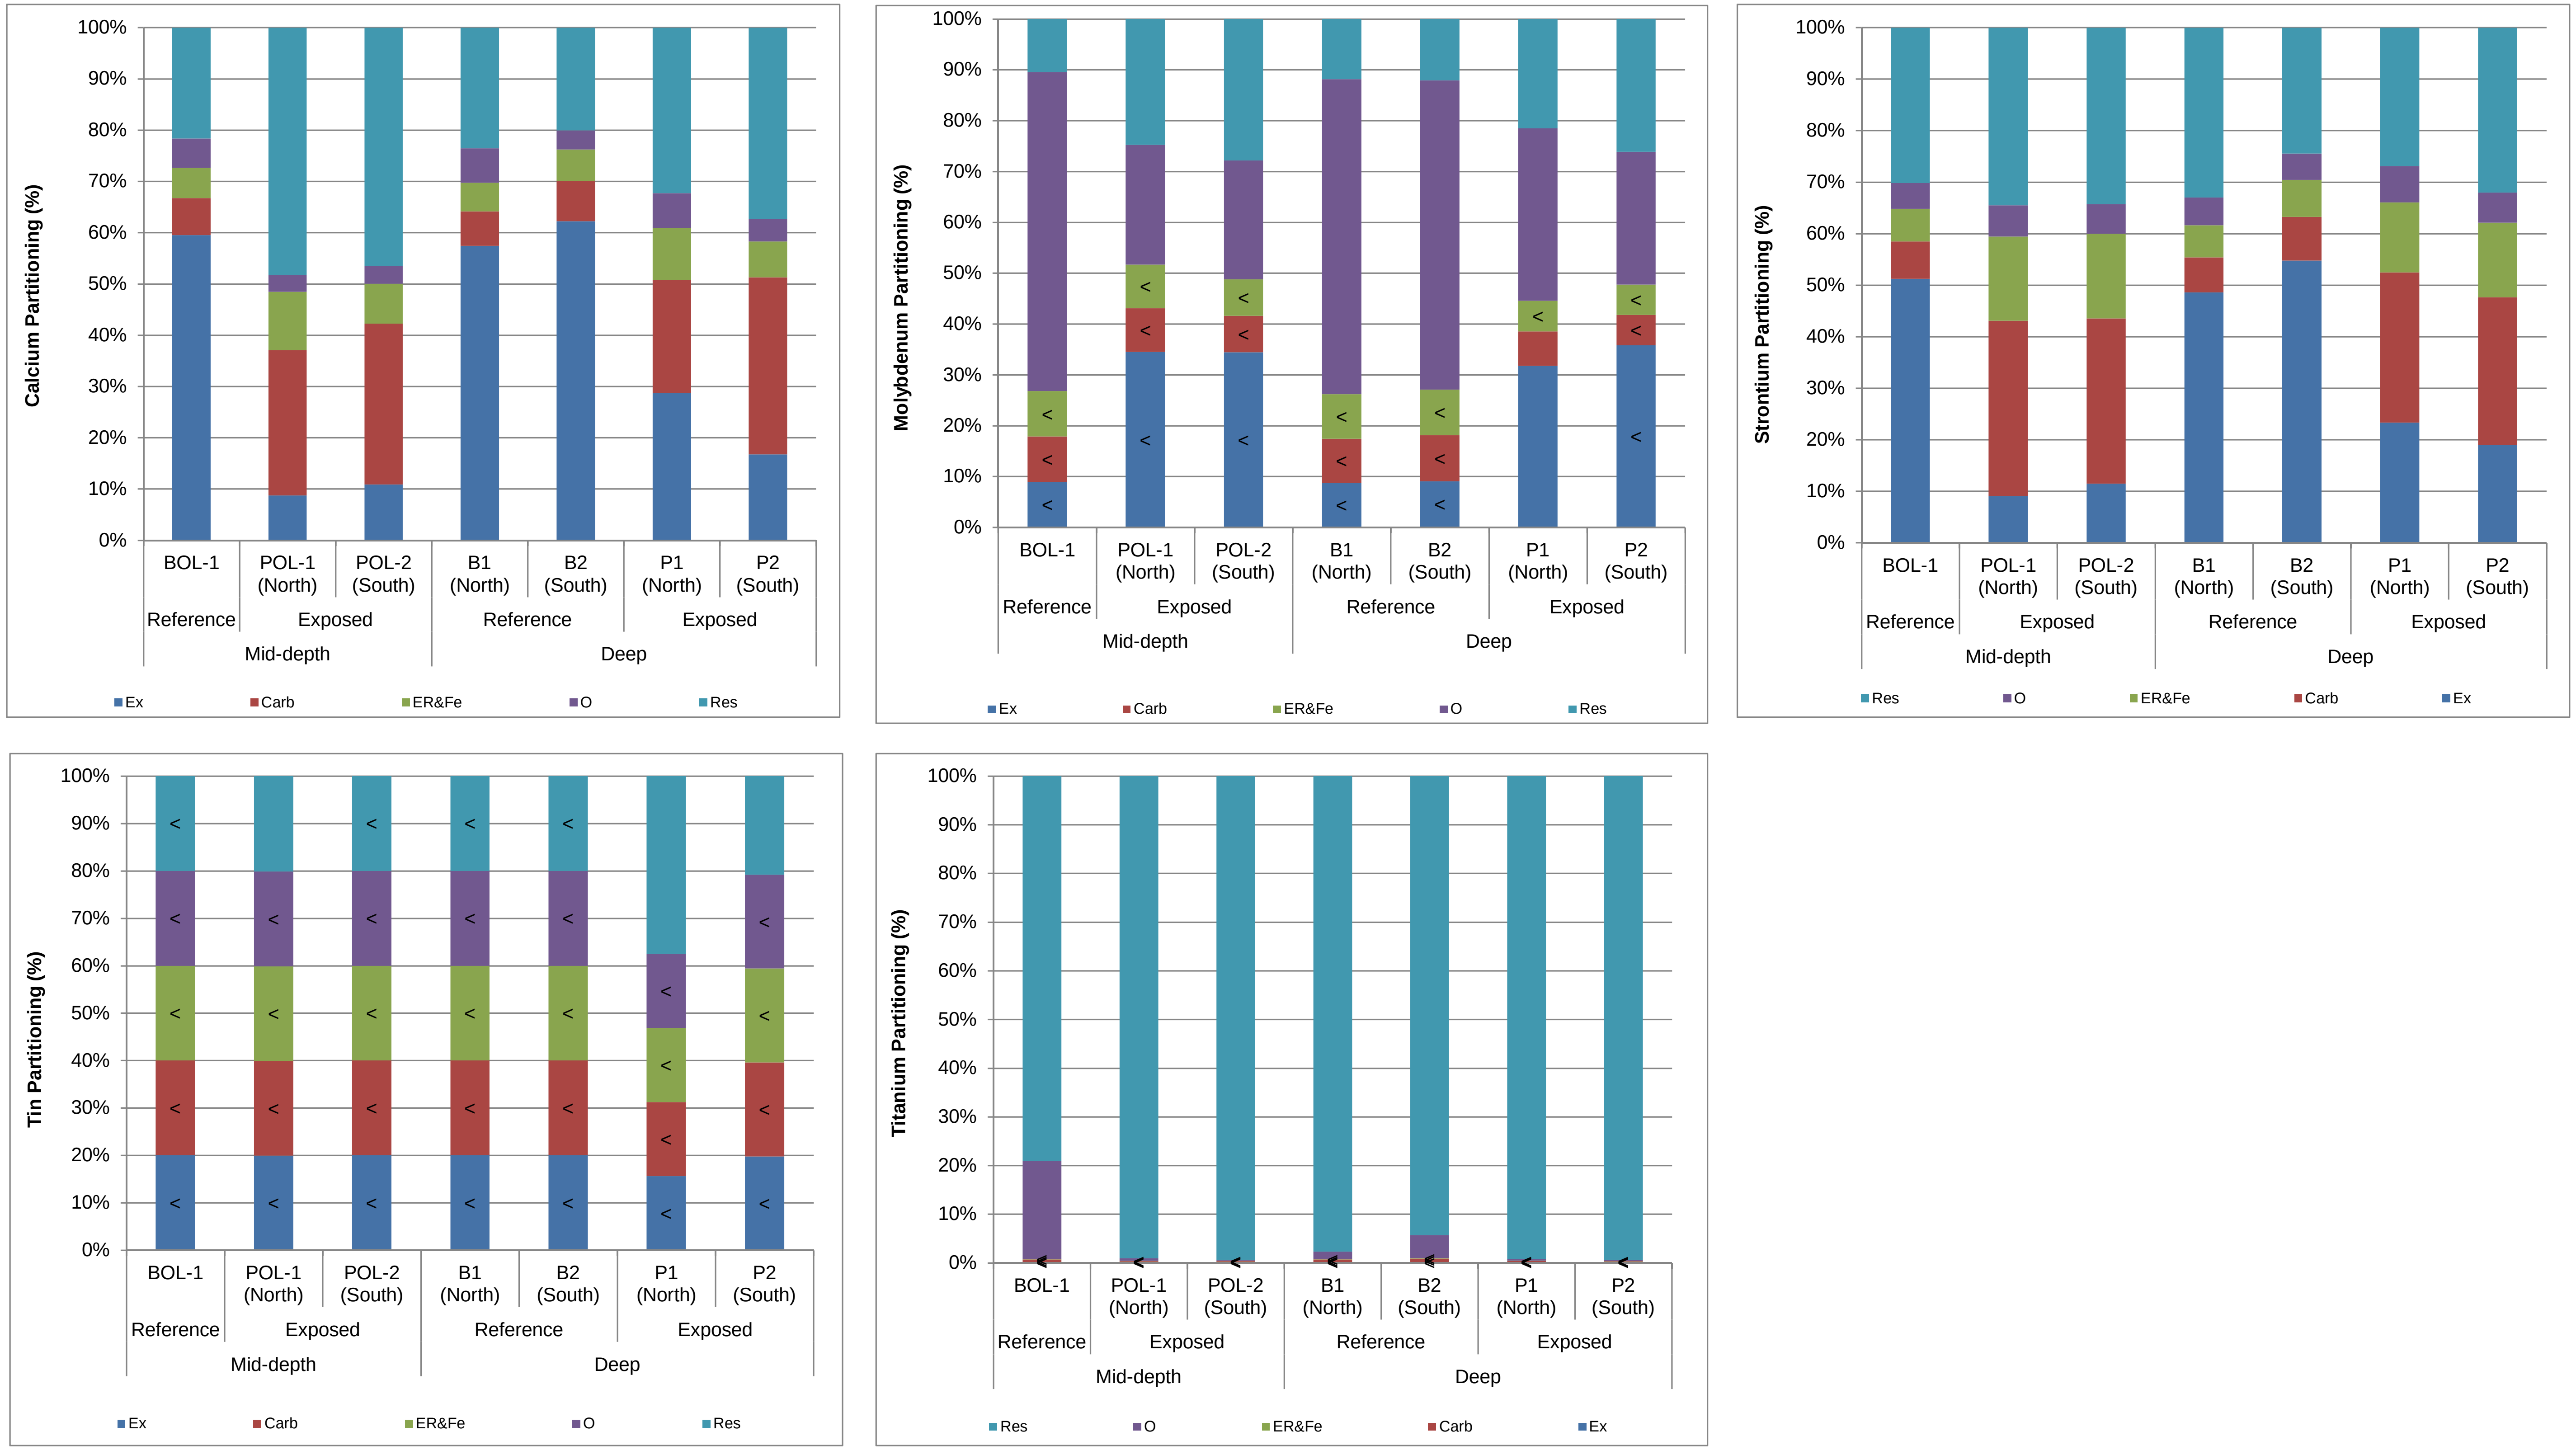

Figure E.16 (b): Partitioning of selectively extracted indicator parameters in sediment from mid-depth and deep sampling areas of Polley Lake, Mount Polley Mine, 2014. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic Bound Metals (O), and Residual Metals (Res).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL. Sodium data were available only for the Exchangeable & Adsorbed Metals fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result.

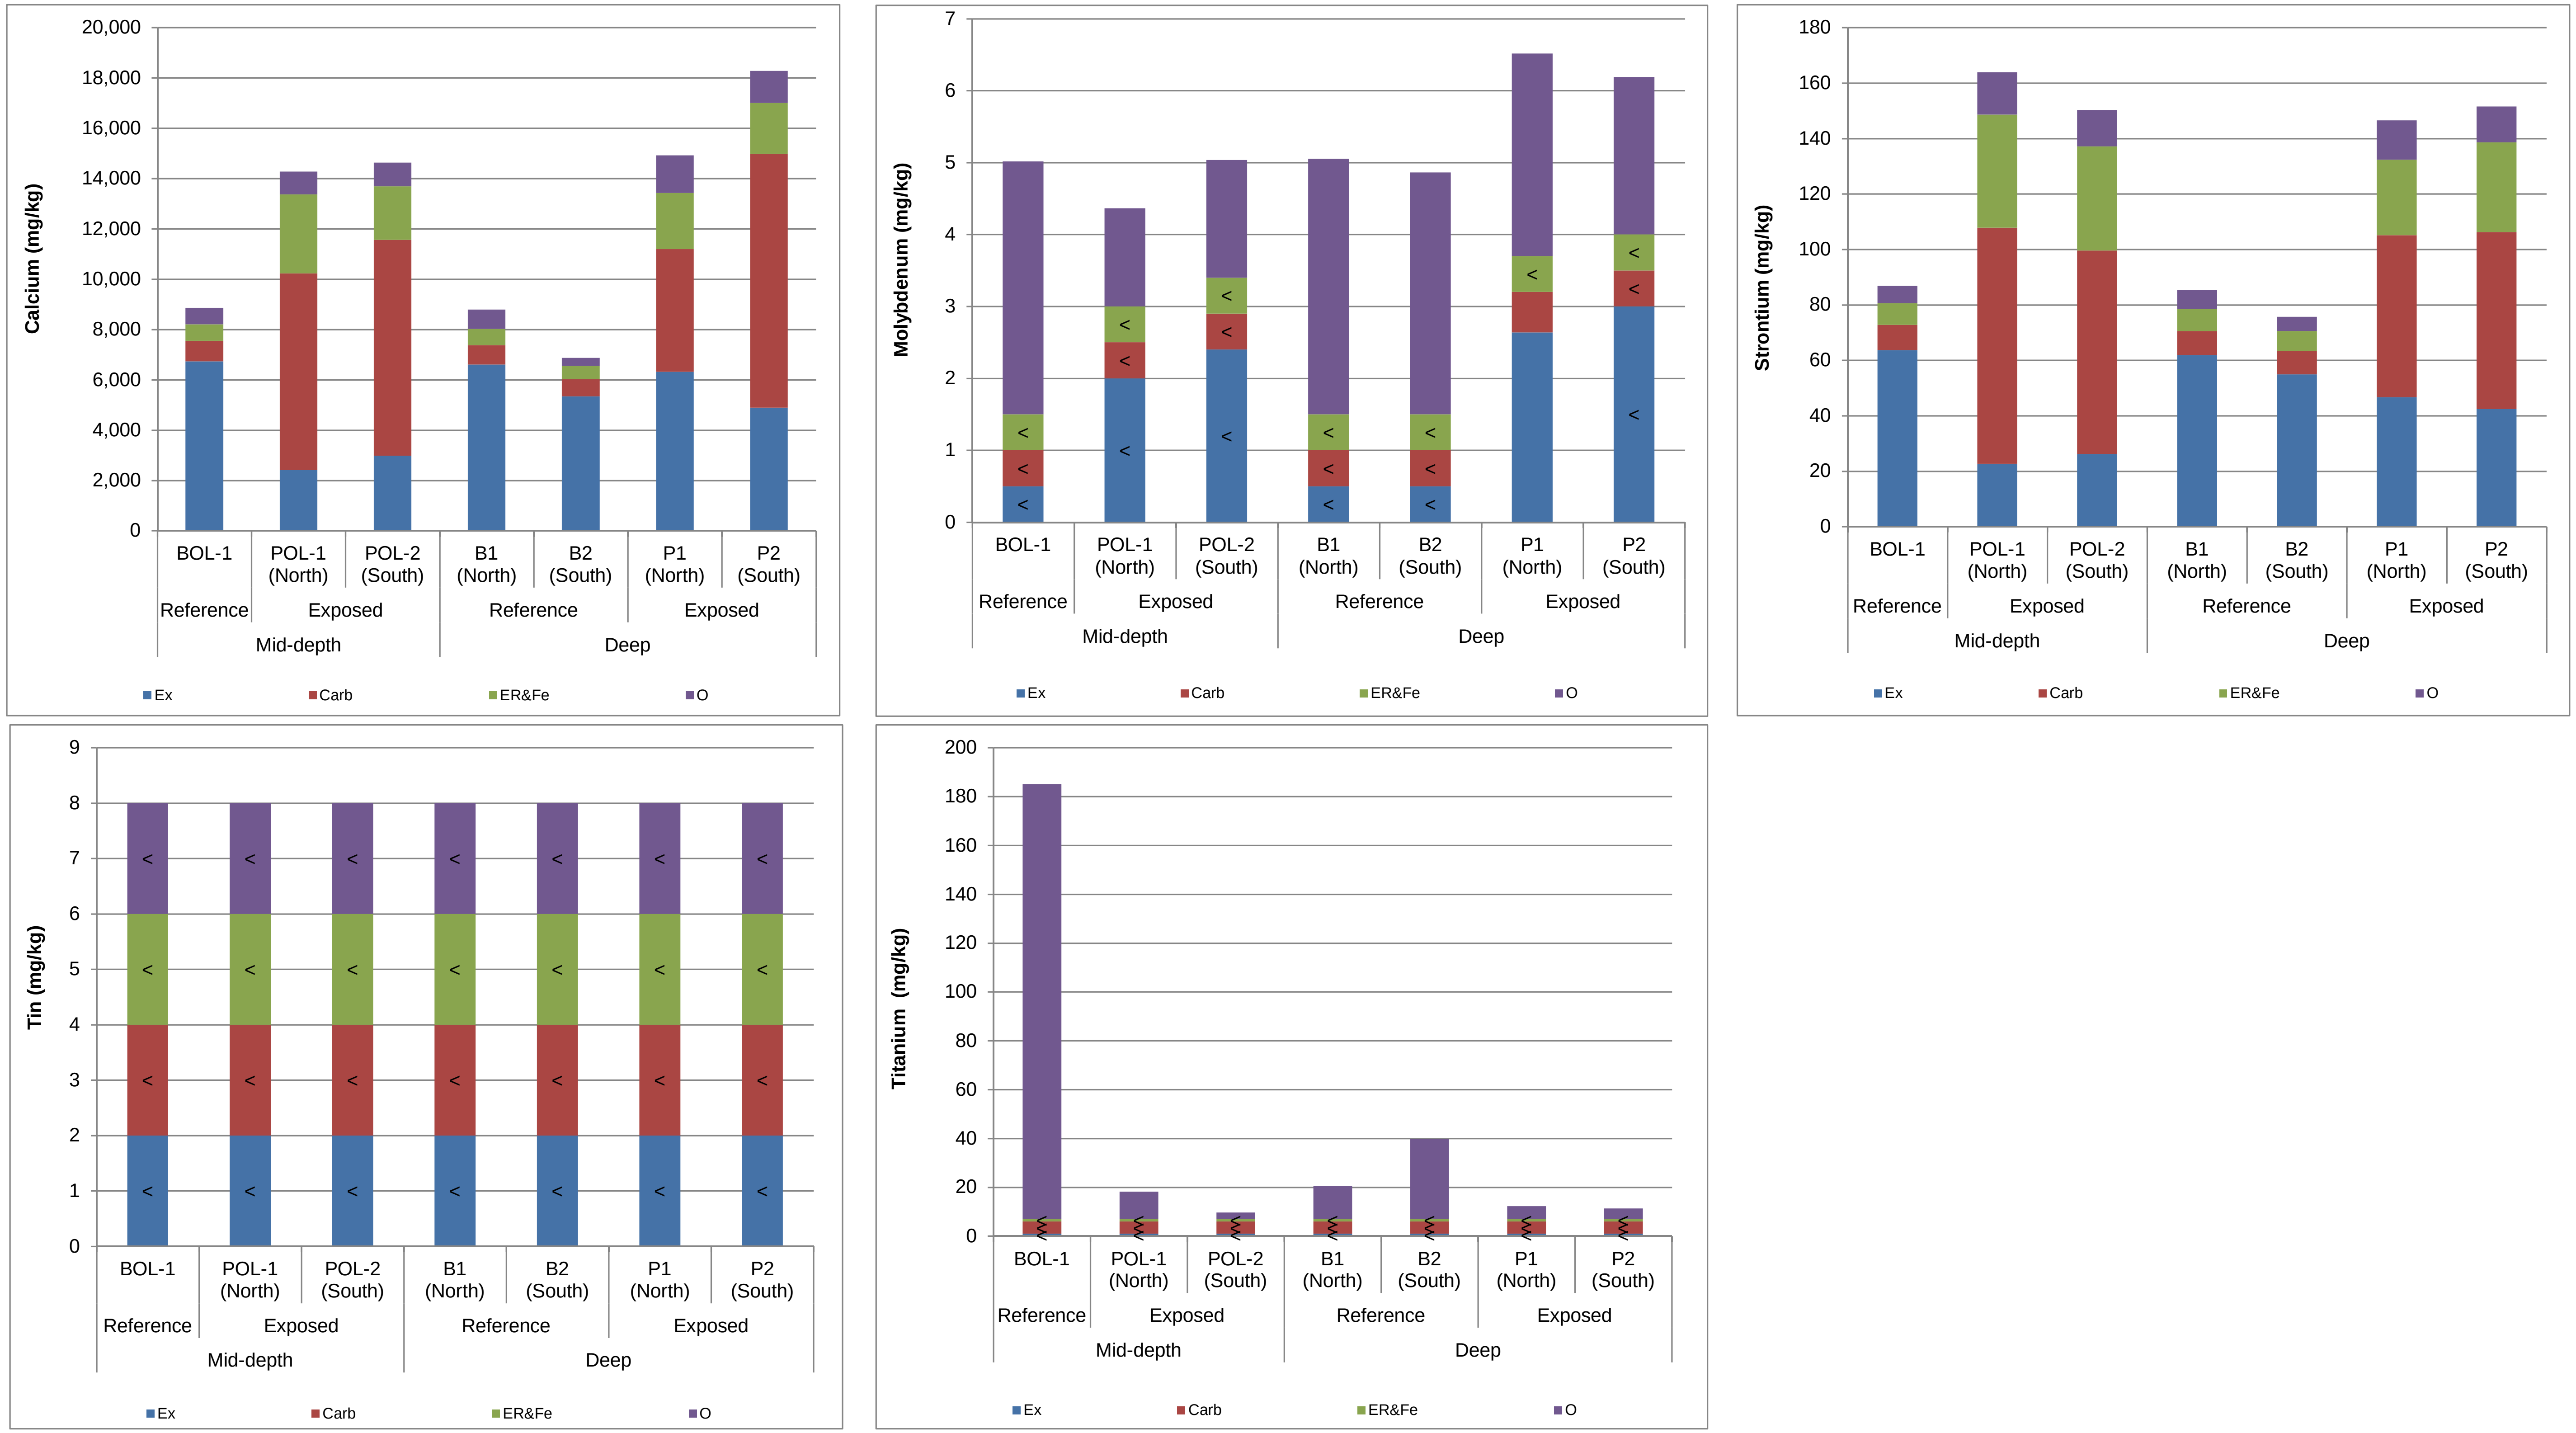

Figure E.16 (c): Mean concentrations of selectively extracted indicator parameters in sediment from mid-depth and deep sampling areas of Polley Lake, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) and Organic Bound Metals (O) fractions are shown (Residual metals are excluded).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL. Sodium data were available only for the Exchangeable & Adsorbed Metals fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result.

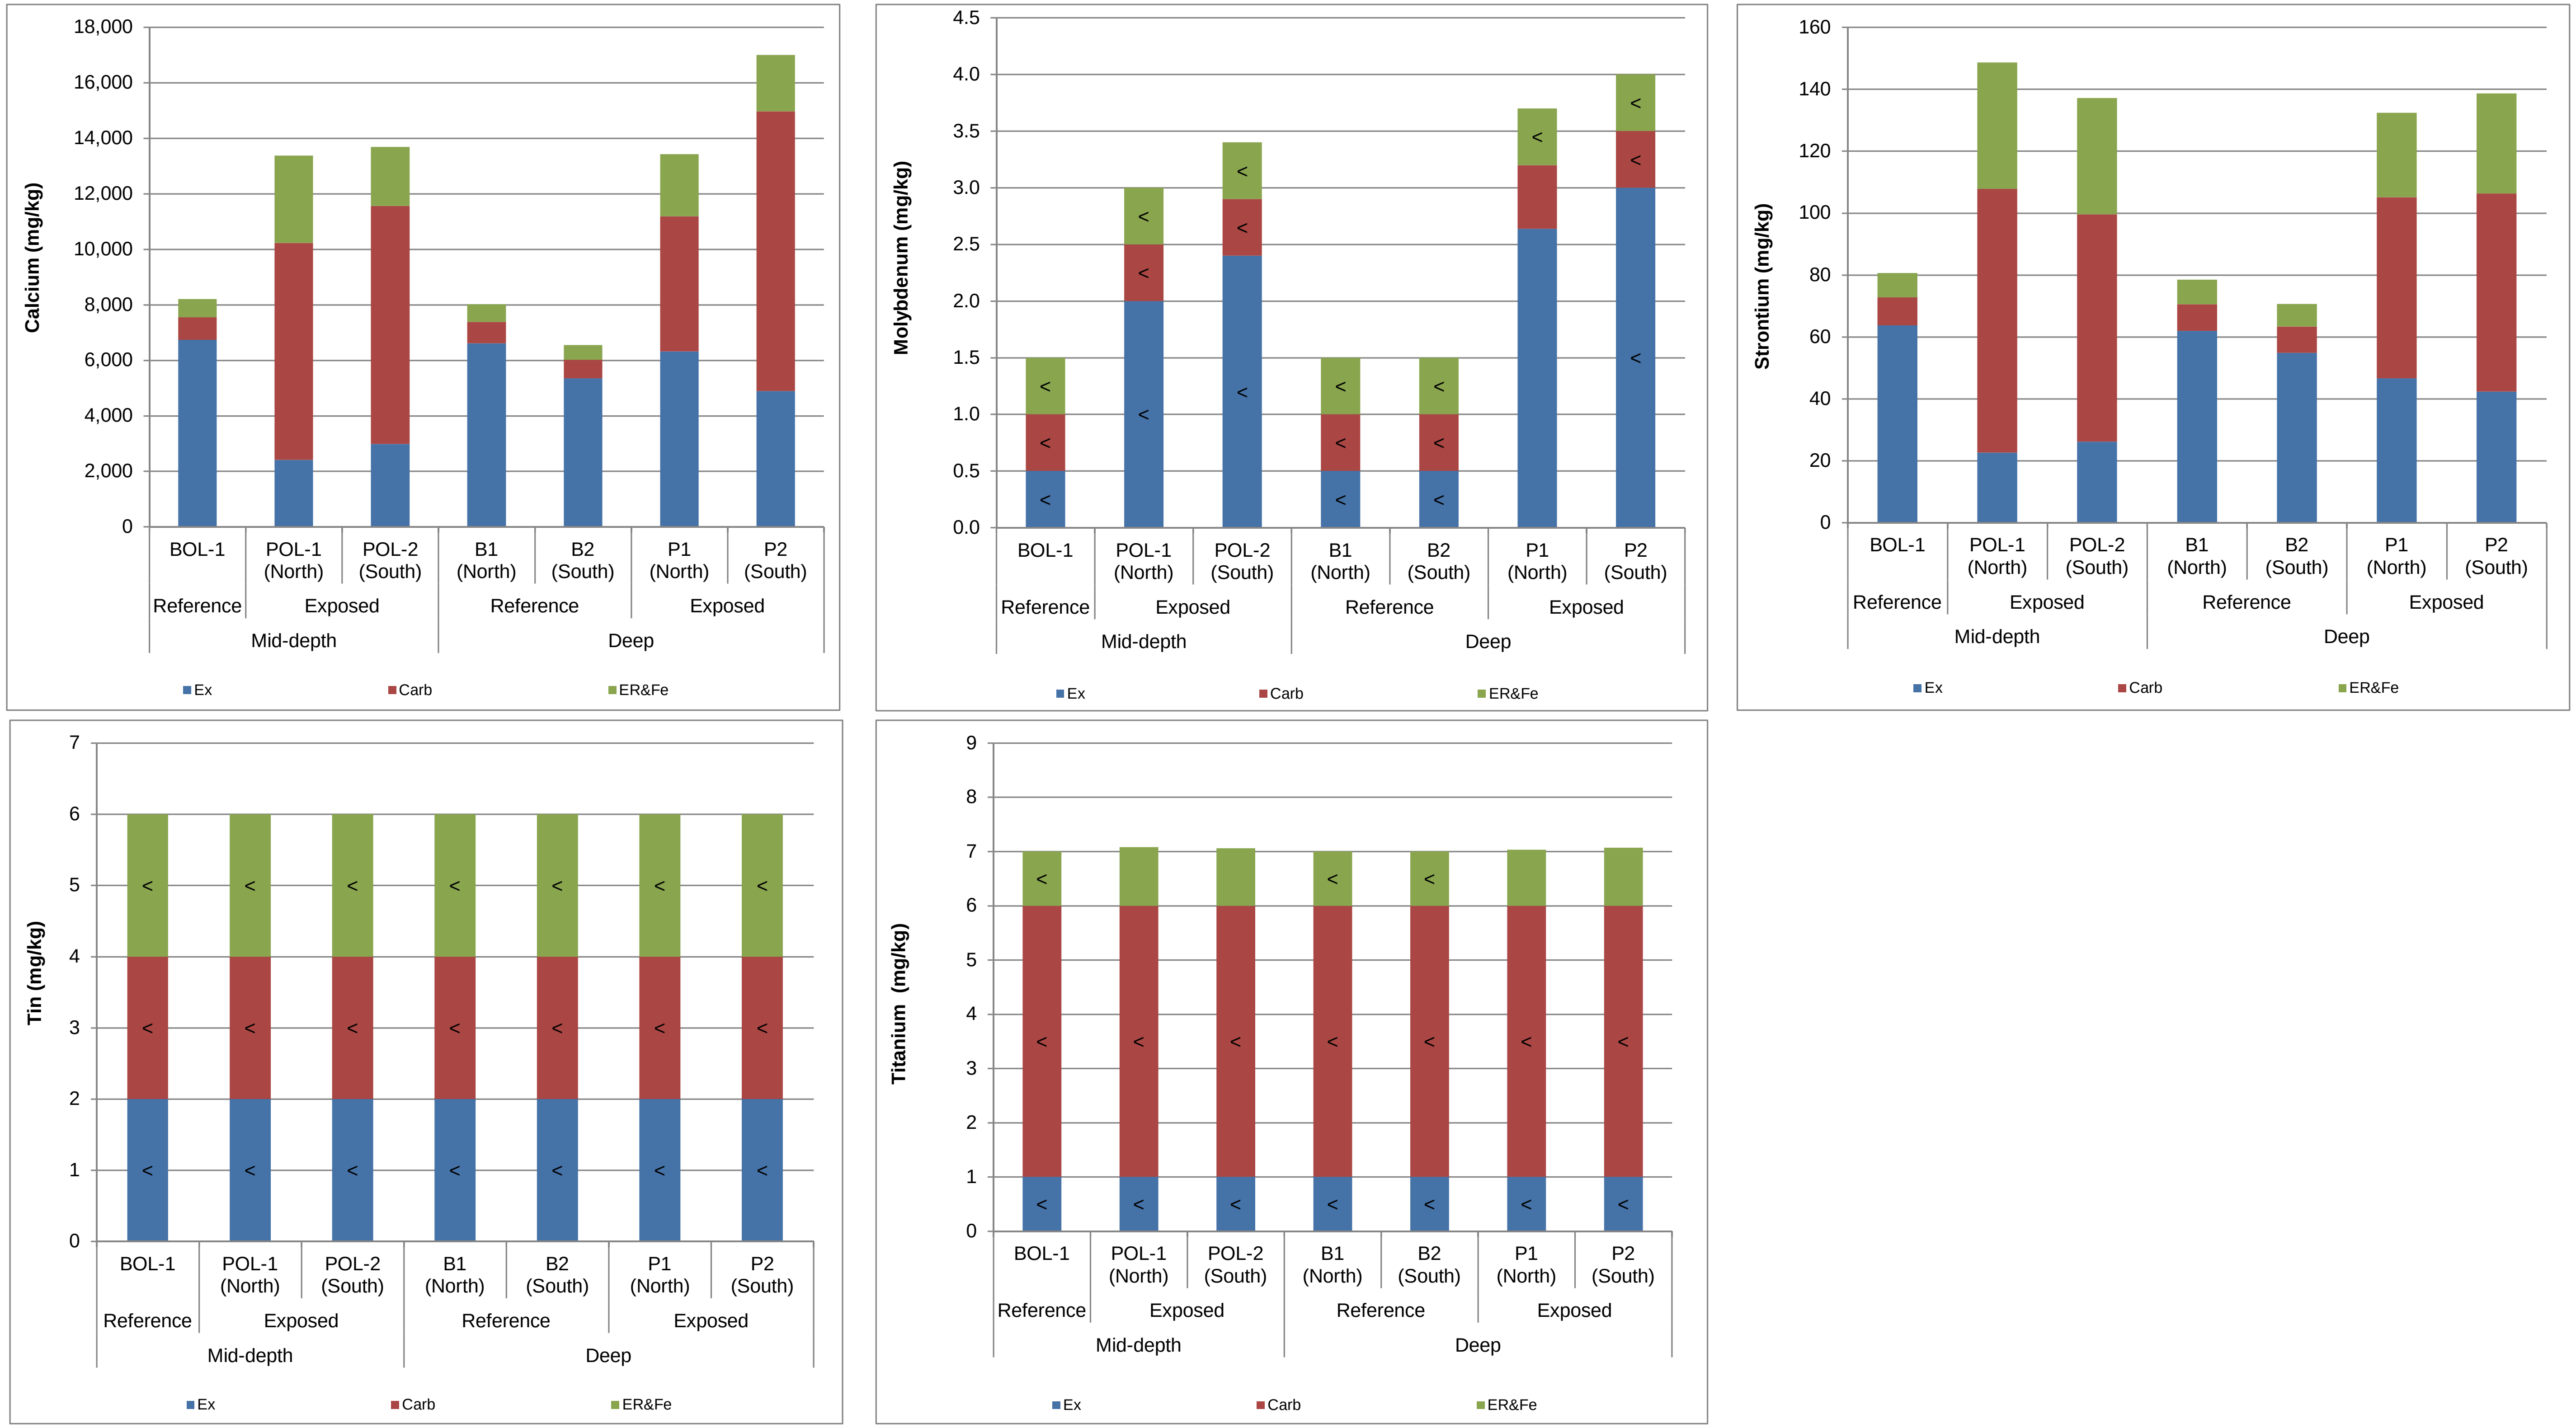

Figure E.16 (d): Mean concentrations of selectively extracted indicator parameters in sediment from mid-depth and deep sampling areas of Polley Lake, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) fractions are shown (Organic Bound and Residual metals are excluded).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL. Sodium data were available only for the Exchangeable & Adsorbed Metals fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result.

Figure E.17: Sediment cores collected from Polley Lake north basin (POL-P1) for profiles of sediment chemistry (left core) and pore-water chemistry (right core).

Figure E.18: Sediment cores collected from Polley Lake south basin (POL-P2) for profiles of sediment chemistry (left core) and pore-water chemistry (right core).

Figure E.19: The 9 to 10 cm sediment section of the core collected from Polley Lake south basin (POL-P2) and used for sediment chemistry analysis. The sediment section shows clay-like sediments (to the left) at the same sediment horizon as grey tailings material (to the right).

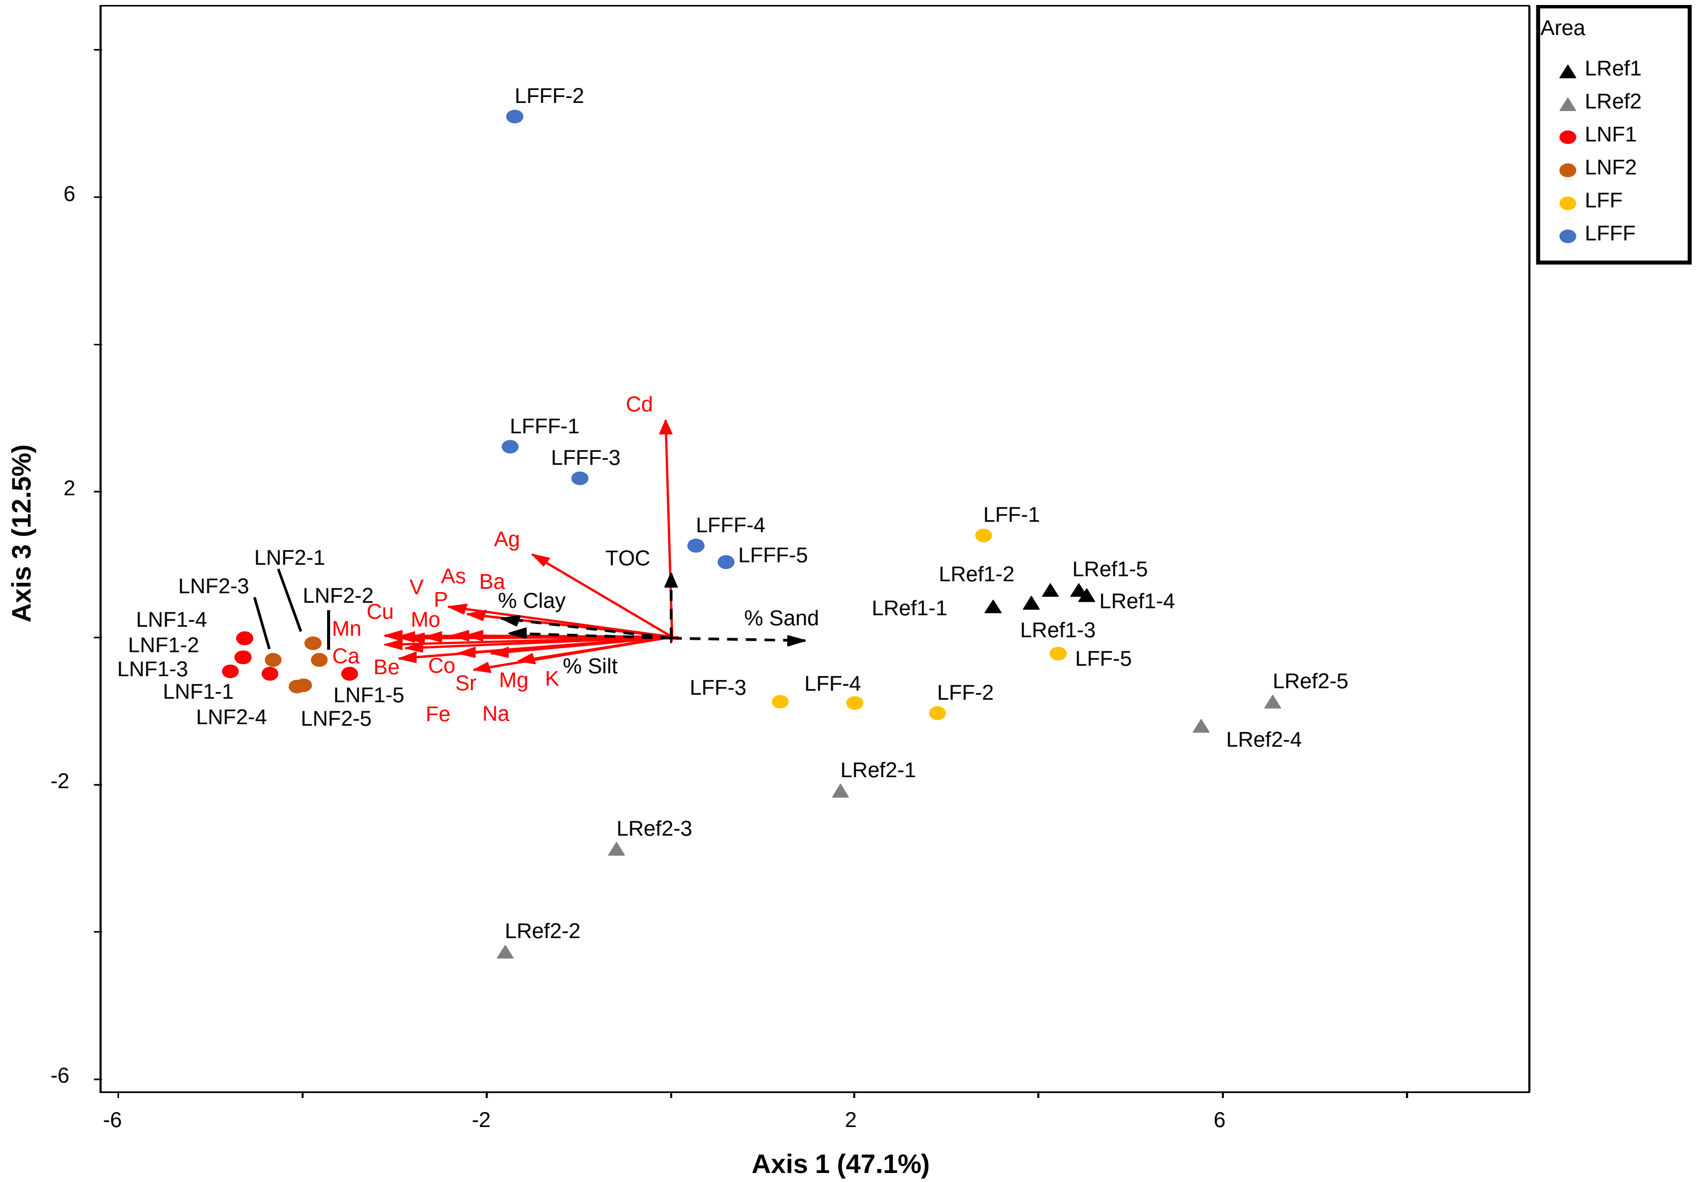

Figure E.20: **Biplot of principal component analysis (PCA) of metal concentrations in sediment (<2 mm fraction) from Quesnel Lake littoral sampling stations, Mount Polley Mine, 2014. Vector length is proportional to the magnitude of direct correlation of metals (solid red vector lines) and indirect correlation of sediment physical characteristics (black dashed vector lines) with PCA values of each axis (Appendix Tables E.47-E.48). Only metals with significant (p-value <0.010) Spearman's correlation and r-values > 0.7 with either axis are displayed, all sediment physical characteristics are displayed [a].**

[a] Boron, mercury, and tin were excluded from calculations due to a lack of variability in the data (all values for each analyte were the same), or an incomplete data set.

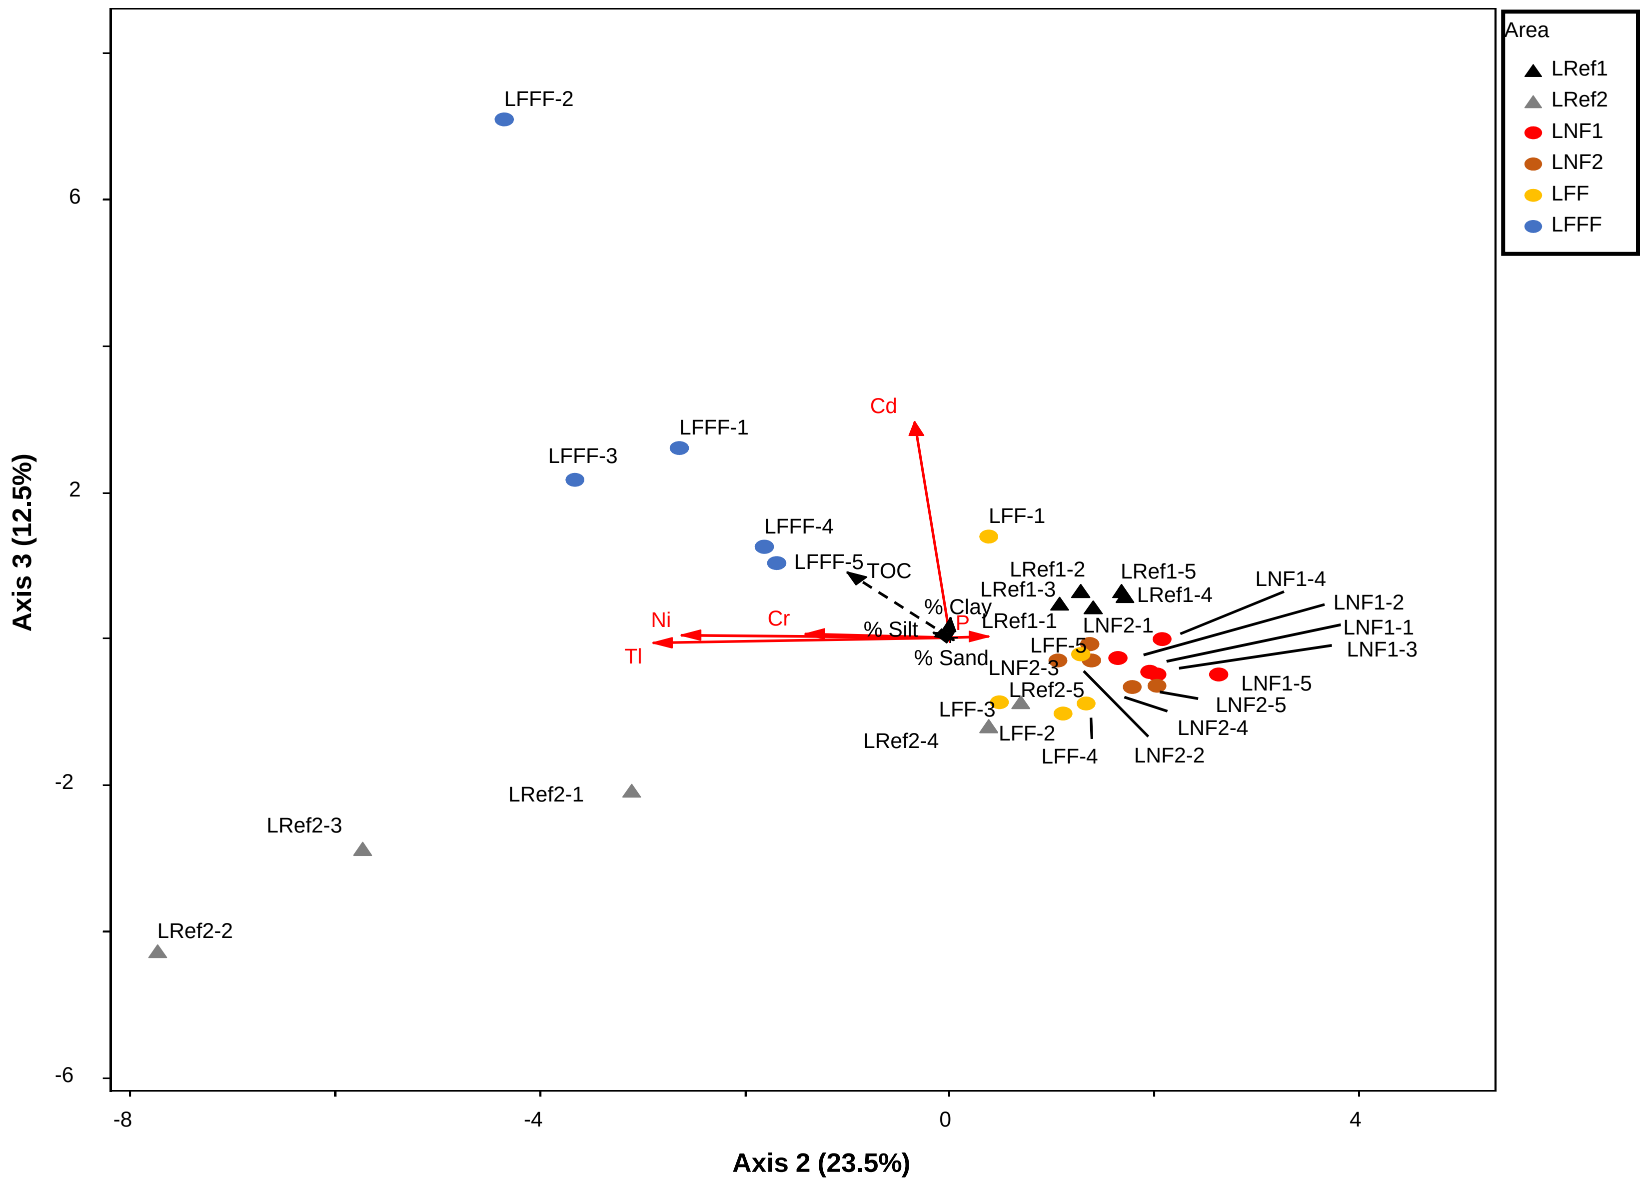

Figure E.21: Biplot of principal component analysis (PCA) of metal concentrations in sediment (<2 mm fraction) from Quesnel Lake littoral sampling stations, Mount Polley Mine, 2014. Vector length is proportional to the magnitude of direct correlation of metals (solid red vector lines) and indirect correlation of sediment physical characteristics (black dashed vector lines) with PCA values of each axis (Appendix Tables E.47-E.48). Only metals with significant (p-value <0.010) Spearman's correlation and r-values > 0.7 with either axis are displayed, all sediment physical characteristics are displayed [a].

[a] Boron, mercury, and tin were excluded from calculations due to a lack of variability in the data (all values for each analyte were the same), or an incomplete data set.

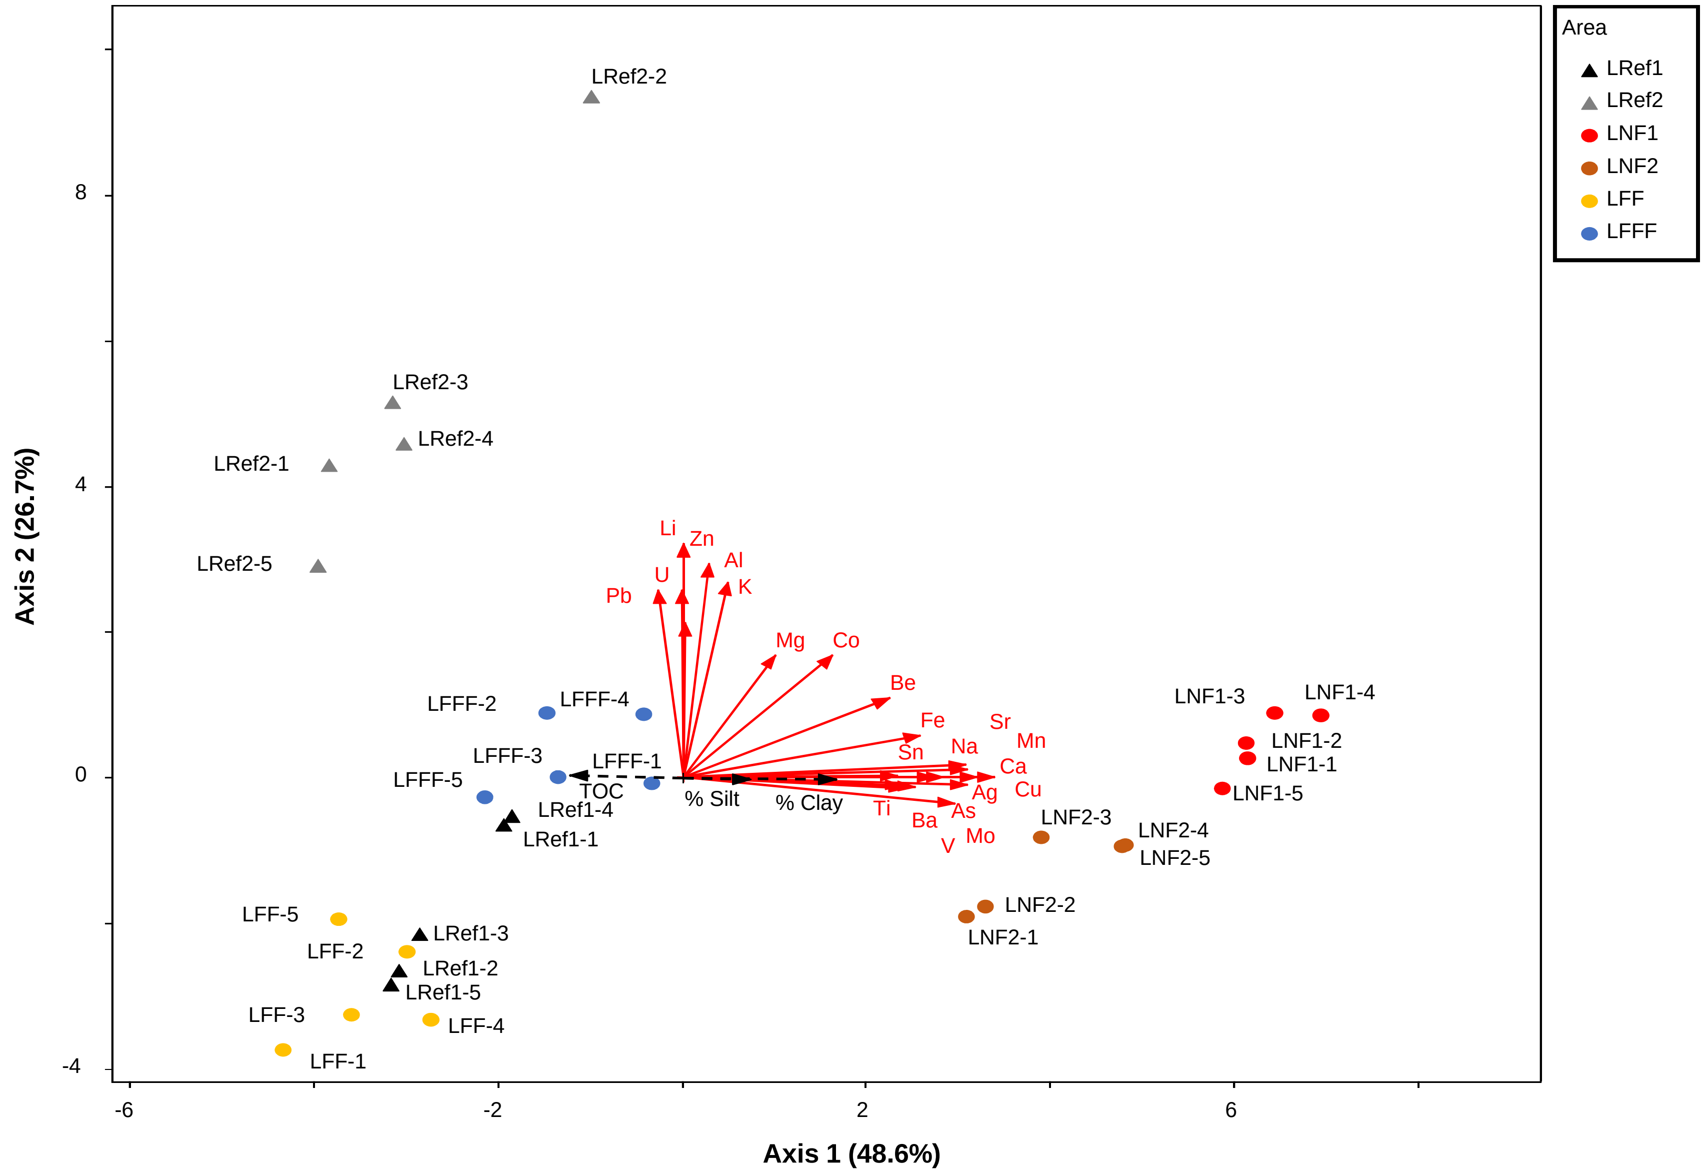

Figure E.22: Biplot of principal component analysis (PCA) of metal concentrations in sediment (<63 µm fraction) from Quesnel Lake littoral sampling stations, Mount Polley Mine, 2014. Vector length is proportional to the magnitude of direct correlation of metals (solid red vector lines) and indirect correlation of sediment physical characteristics (black dashed vector lines) with PCA values of each axis (Appendix Tables E.49-E.50). Only metals with significant (p-value <0.010) Spearman's correlation and r-values > 0.7 with either axis are displayed, all sediment physical characteristics are displayed [a].

[a] Boron was excluded from calculations due to a lack of variability in the data (all values were the same).

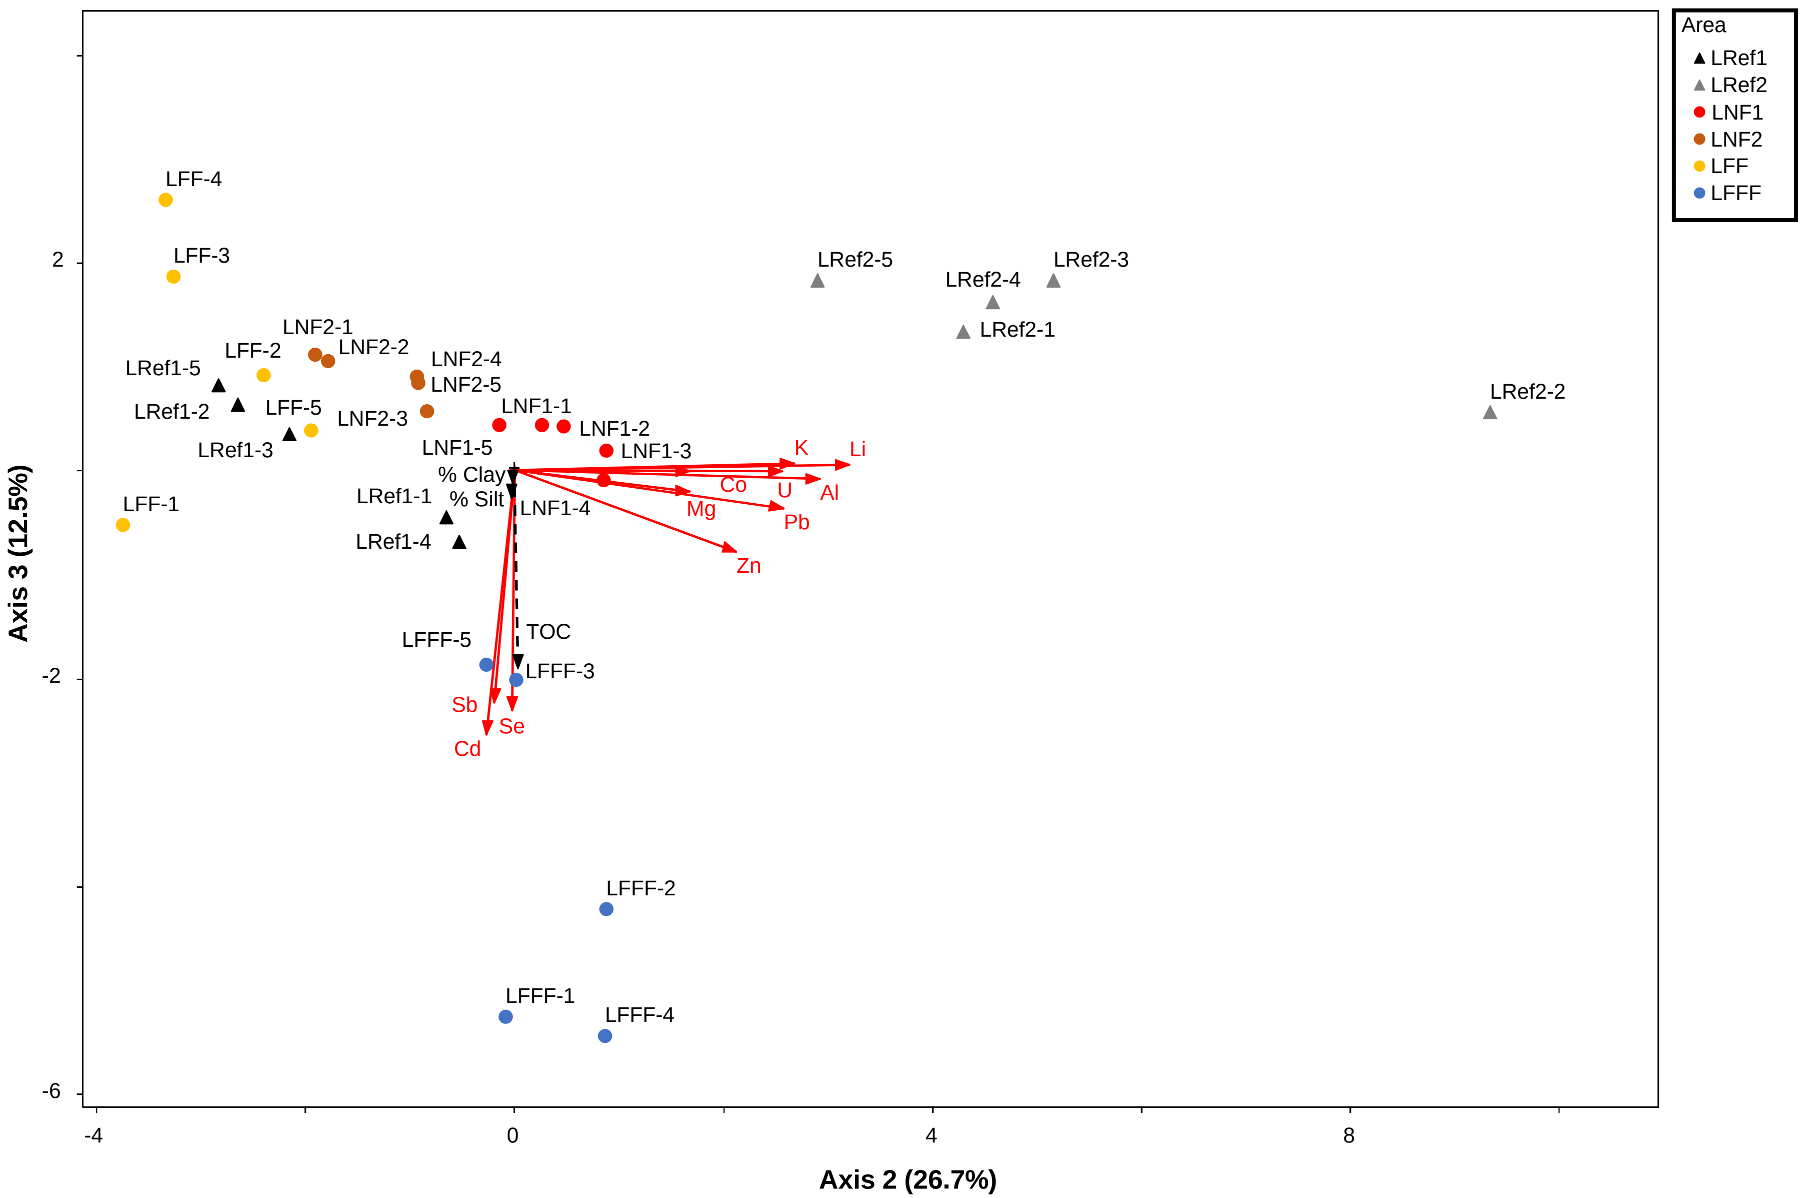

Figure E.23: Biplot of principal component analysis (PCA) of metal concentrations in sediment (<63 µm fraction) from Quesnel Lake littoral sampling stations, Mount Polley Mine, 2014. Vector length is proportional to the magnitude of direct correlation of metals (solid red vector lines) and indirect correlation of sediment physical characteristics (black dashed vector lines) with PCA values of each axis (Appendix Tables E.49-E.50). Only metals with significant (p-value <0.010) Spearman's correlation and r-values > 0.7 with either axis are displayed, all sediment physical characteristics are displayed [a].

[a] Boron was excluded from calculations due to a lack of variability in the data (all values were the same).

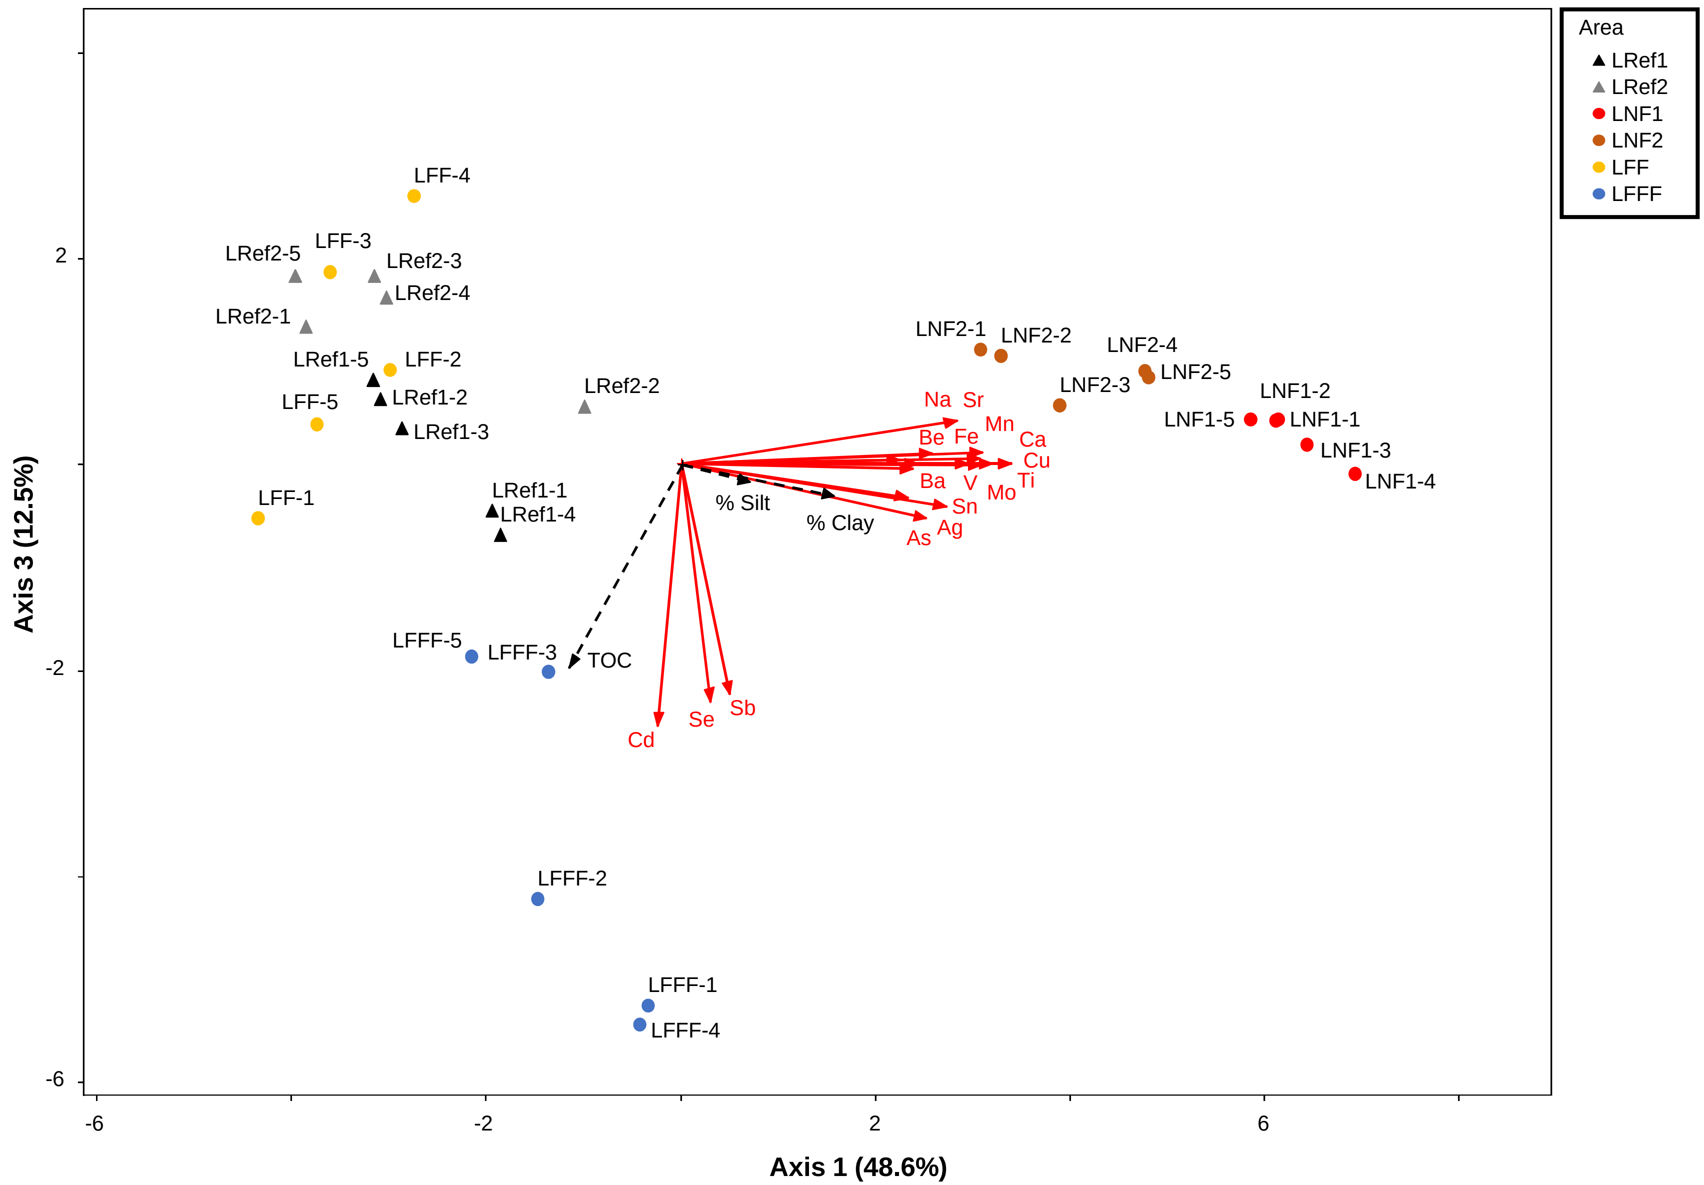

Figure E.24: **Biplot of principal component analysis (PCA) of metal concentrations in sediment (<63 µm fraction) from Quesnel Lake littoral sampling stations, Mount Polley Mine, 2014. Vector length is proportional to the magnitude of direct correlation of metals (solid red vector lines) and indirect correlation of sediment physical characteristics (black dashed vector lines) with PCA values of each axis (Appendix Tables E.49-E.50). Only metals with significant (p-value <0.010) Spearman's correlation and r-values > 0.7 with either axis are displayed, all sediment physical characteristics are displayed [a].**

[a] Boron was excluded from calculations due to a lack of variability in the data (all values were the same).

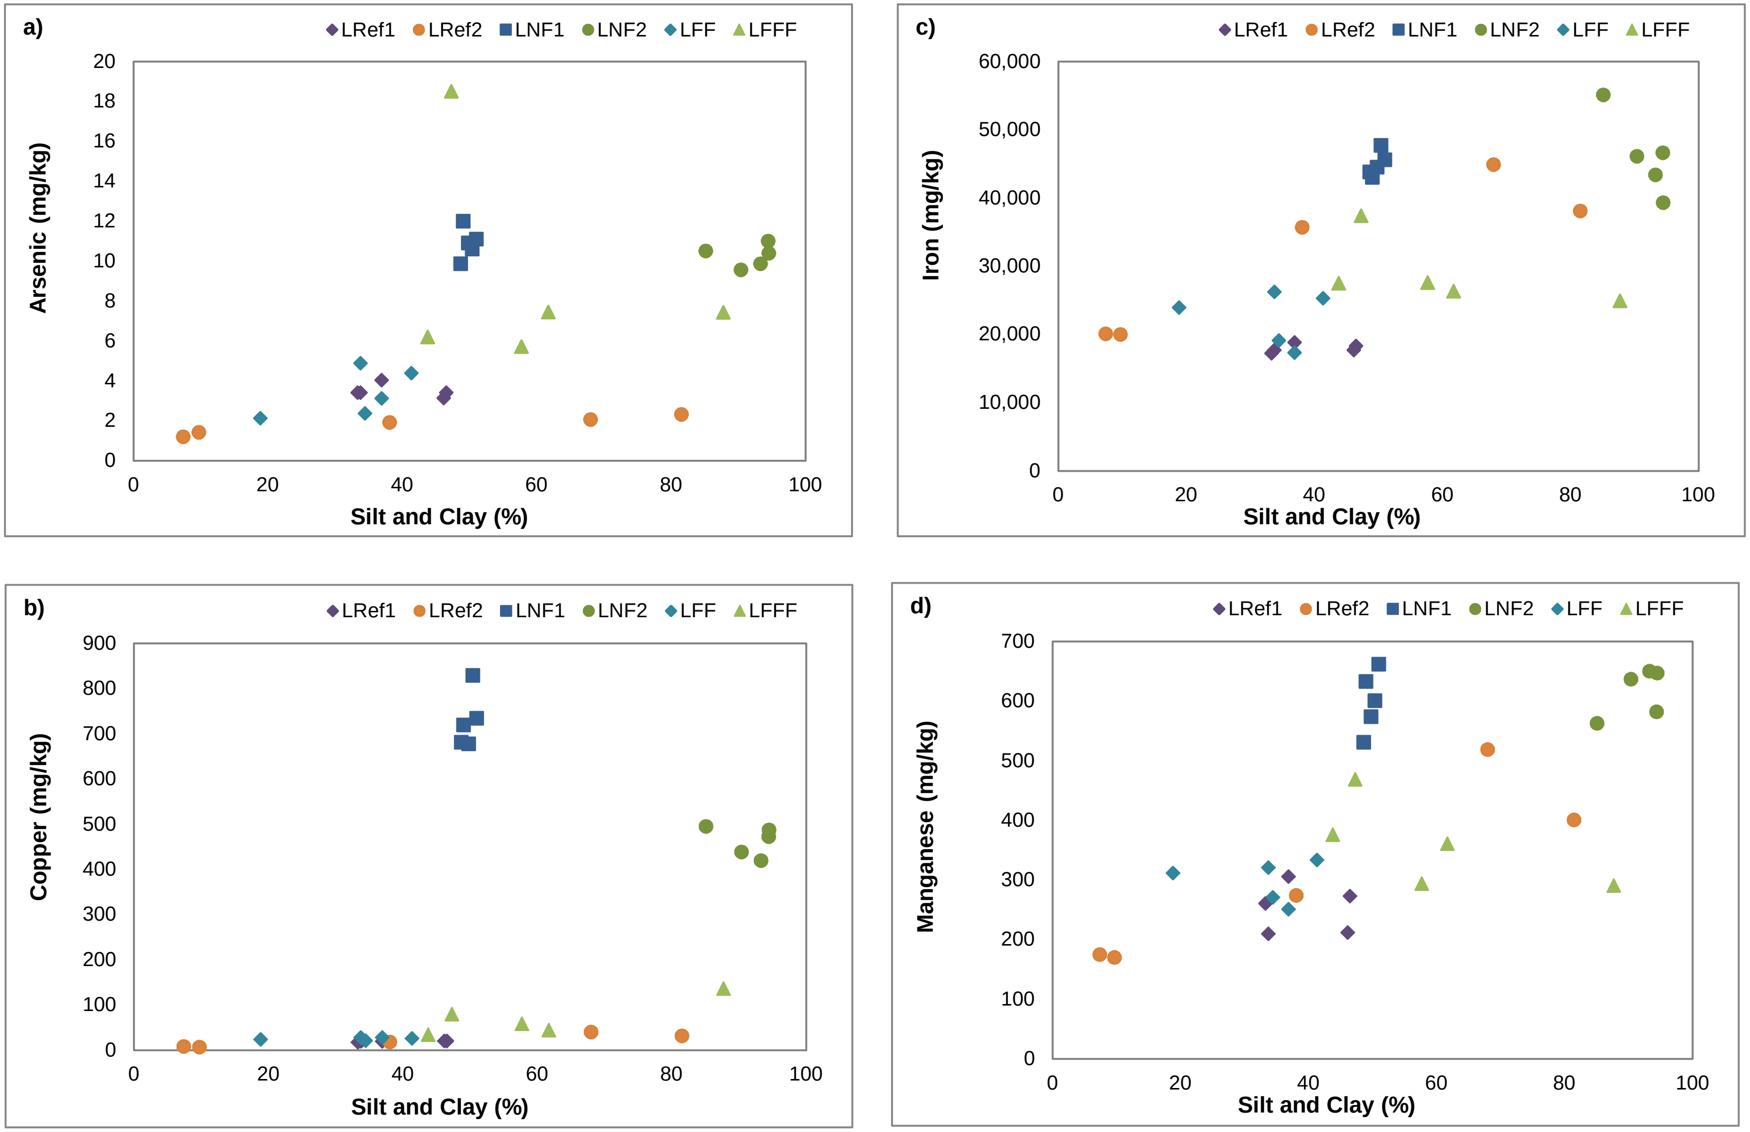

Figure E.25: Scatterplots of significant Spearman correlation relationships (p < 0.002) between silt and clay (%) or total organic carbon (%), and parameters of interest or indicator parameters, Mount Polley Mine 2014. Quesnel Lake Littoral sampling areas. Hollow symbols indicate values < MDL.

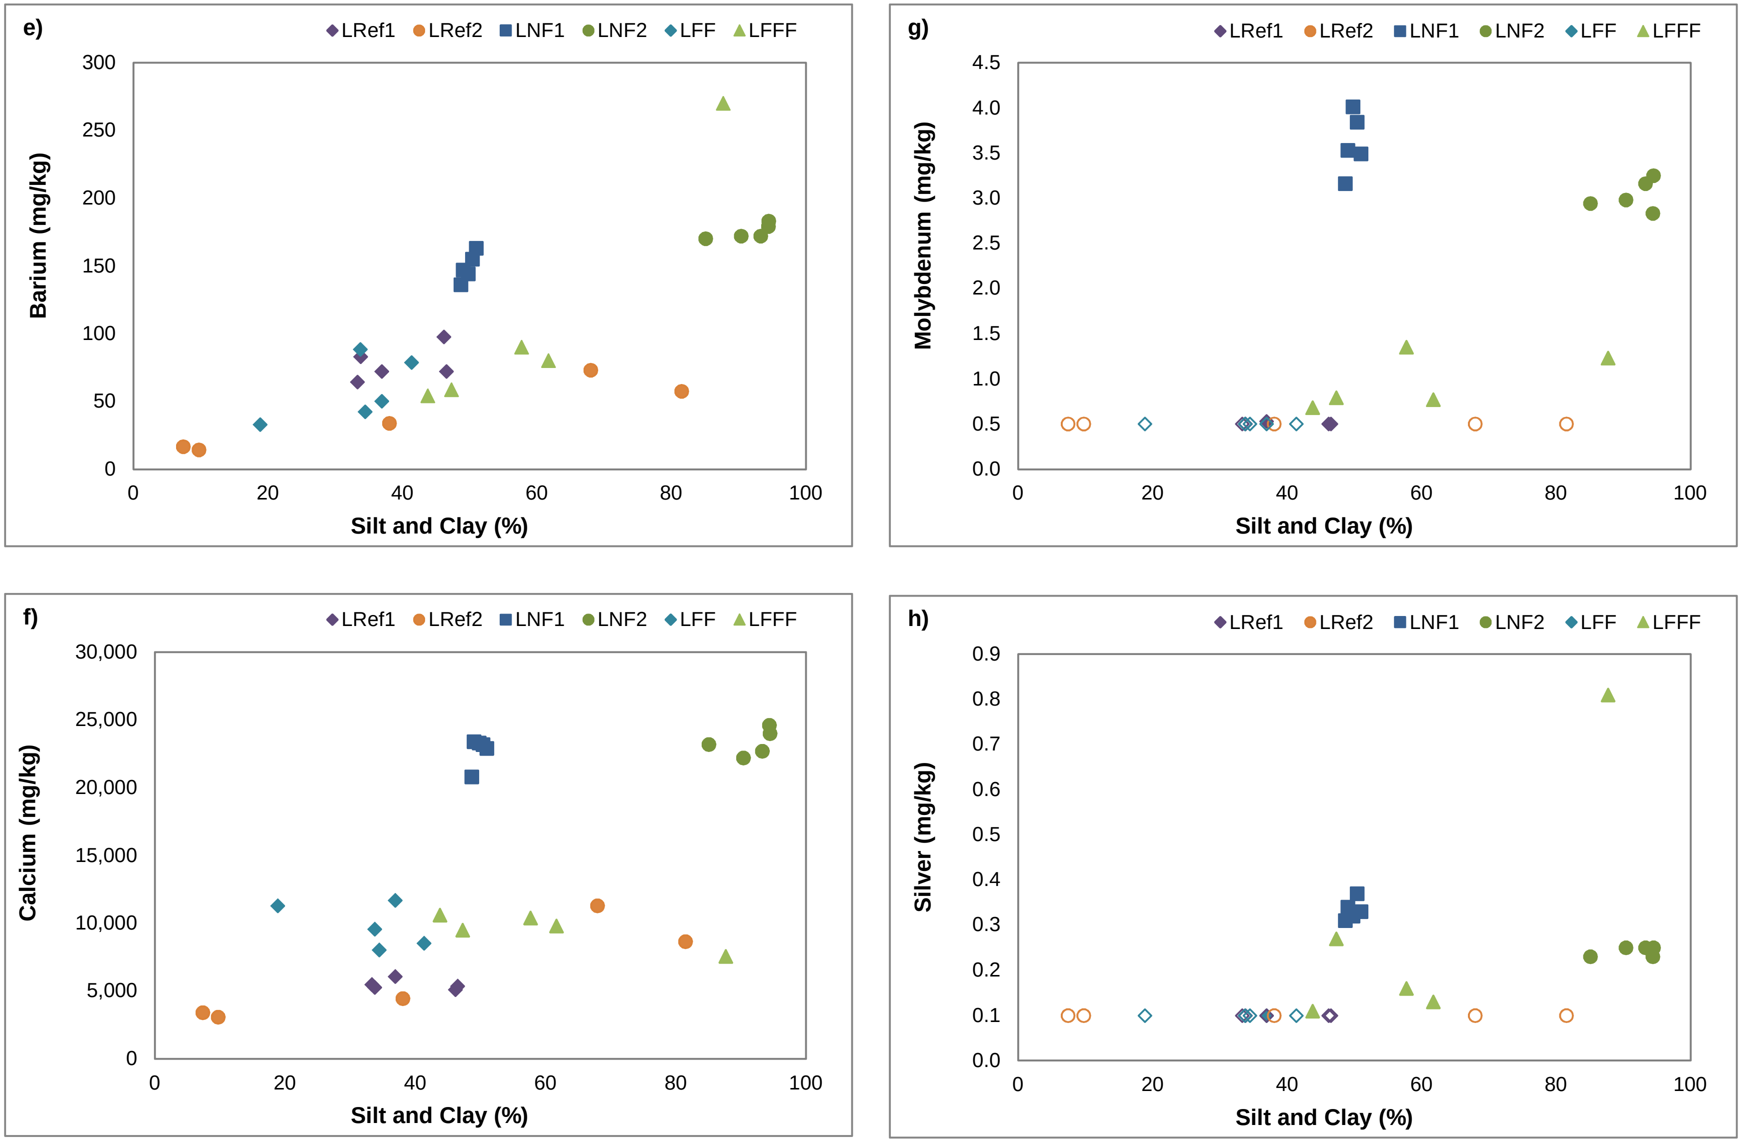

Figure E.25: Scatterplots of significant Spearman correlation relationships ($p < 0.002$) between silt and clay (%) or total organic carbon (%), and parameters of interest or indicator parameters, Mount Polley Mine 2014. Quesnel Lake Littoral sampling areas. Hollow symbols indicate values < MDL.

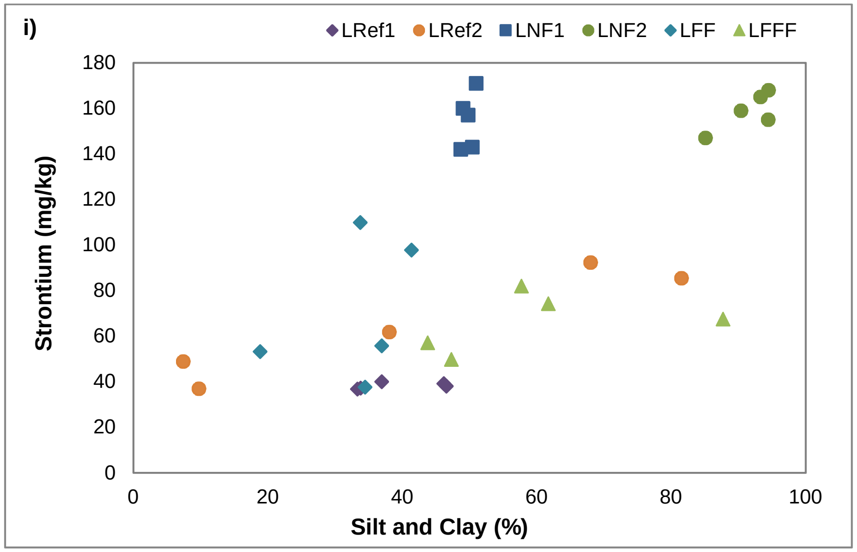

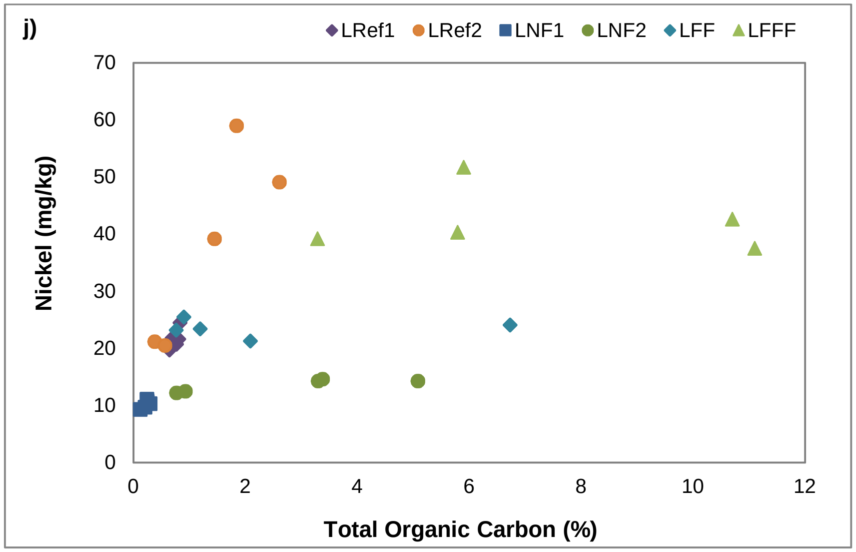

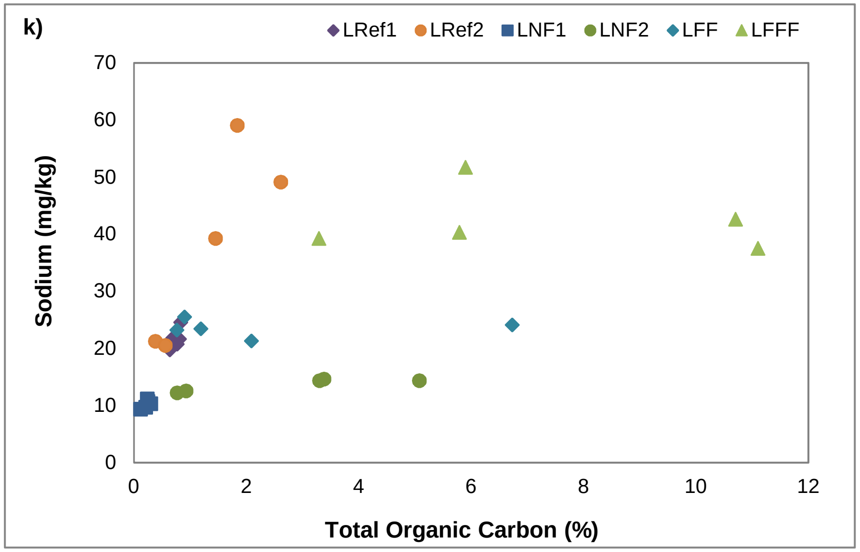

Figure E.25: Scatterplots of significant Spearman correlation relationships ($p < 0.002$) between silt and clay (%) or total organic carbon (%), and parameters of interest or indicator parameters, Mount Polley Mine 2014. Quesnel Lake Littoral sampling areas. Hollow symbols indicate values < MDL.

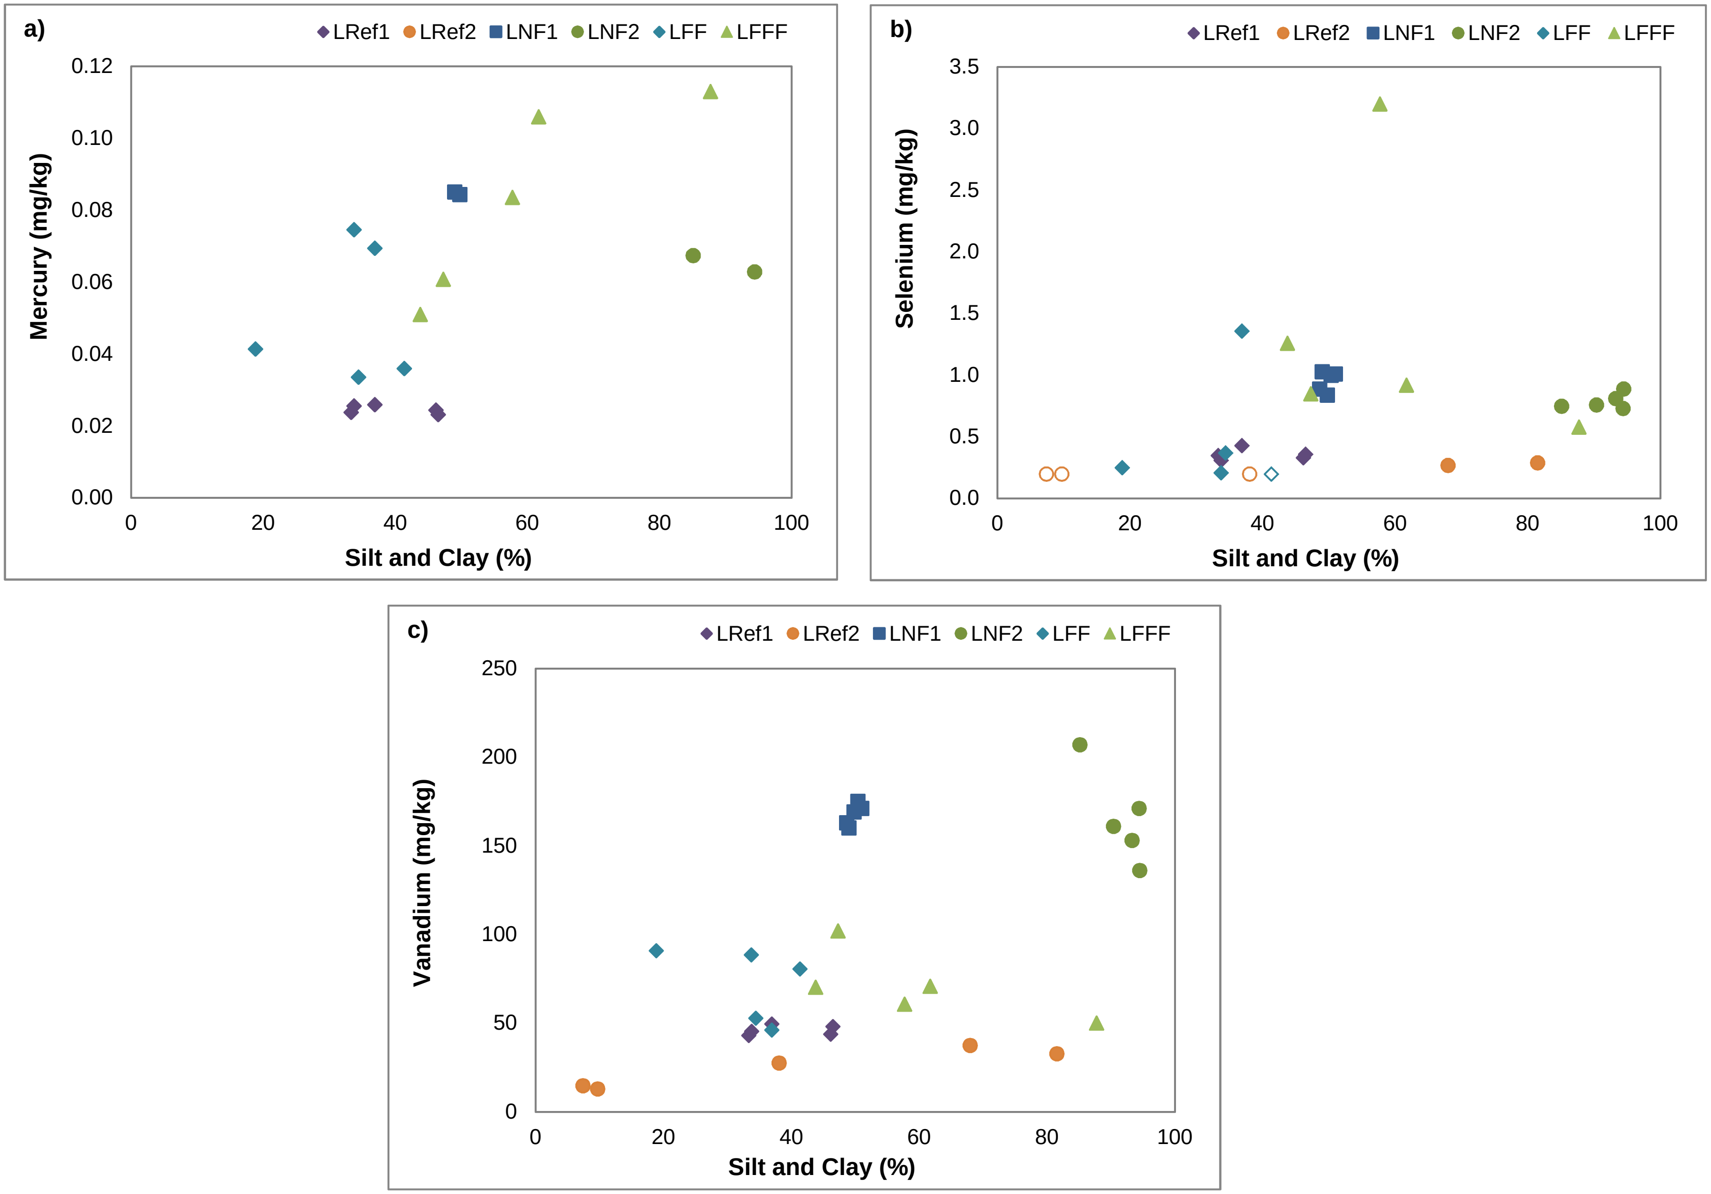

Figure E.26: Scatterplots of Spearman correlation relationships (p < 0.01) between silt and clay (%) and indicator parameters, Mount Polley Mine, 2014. Quesnel Lake Littoral sampling areas. Hollow symbols indicate values < MDL.

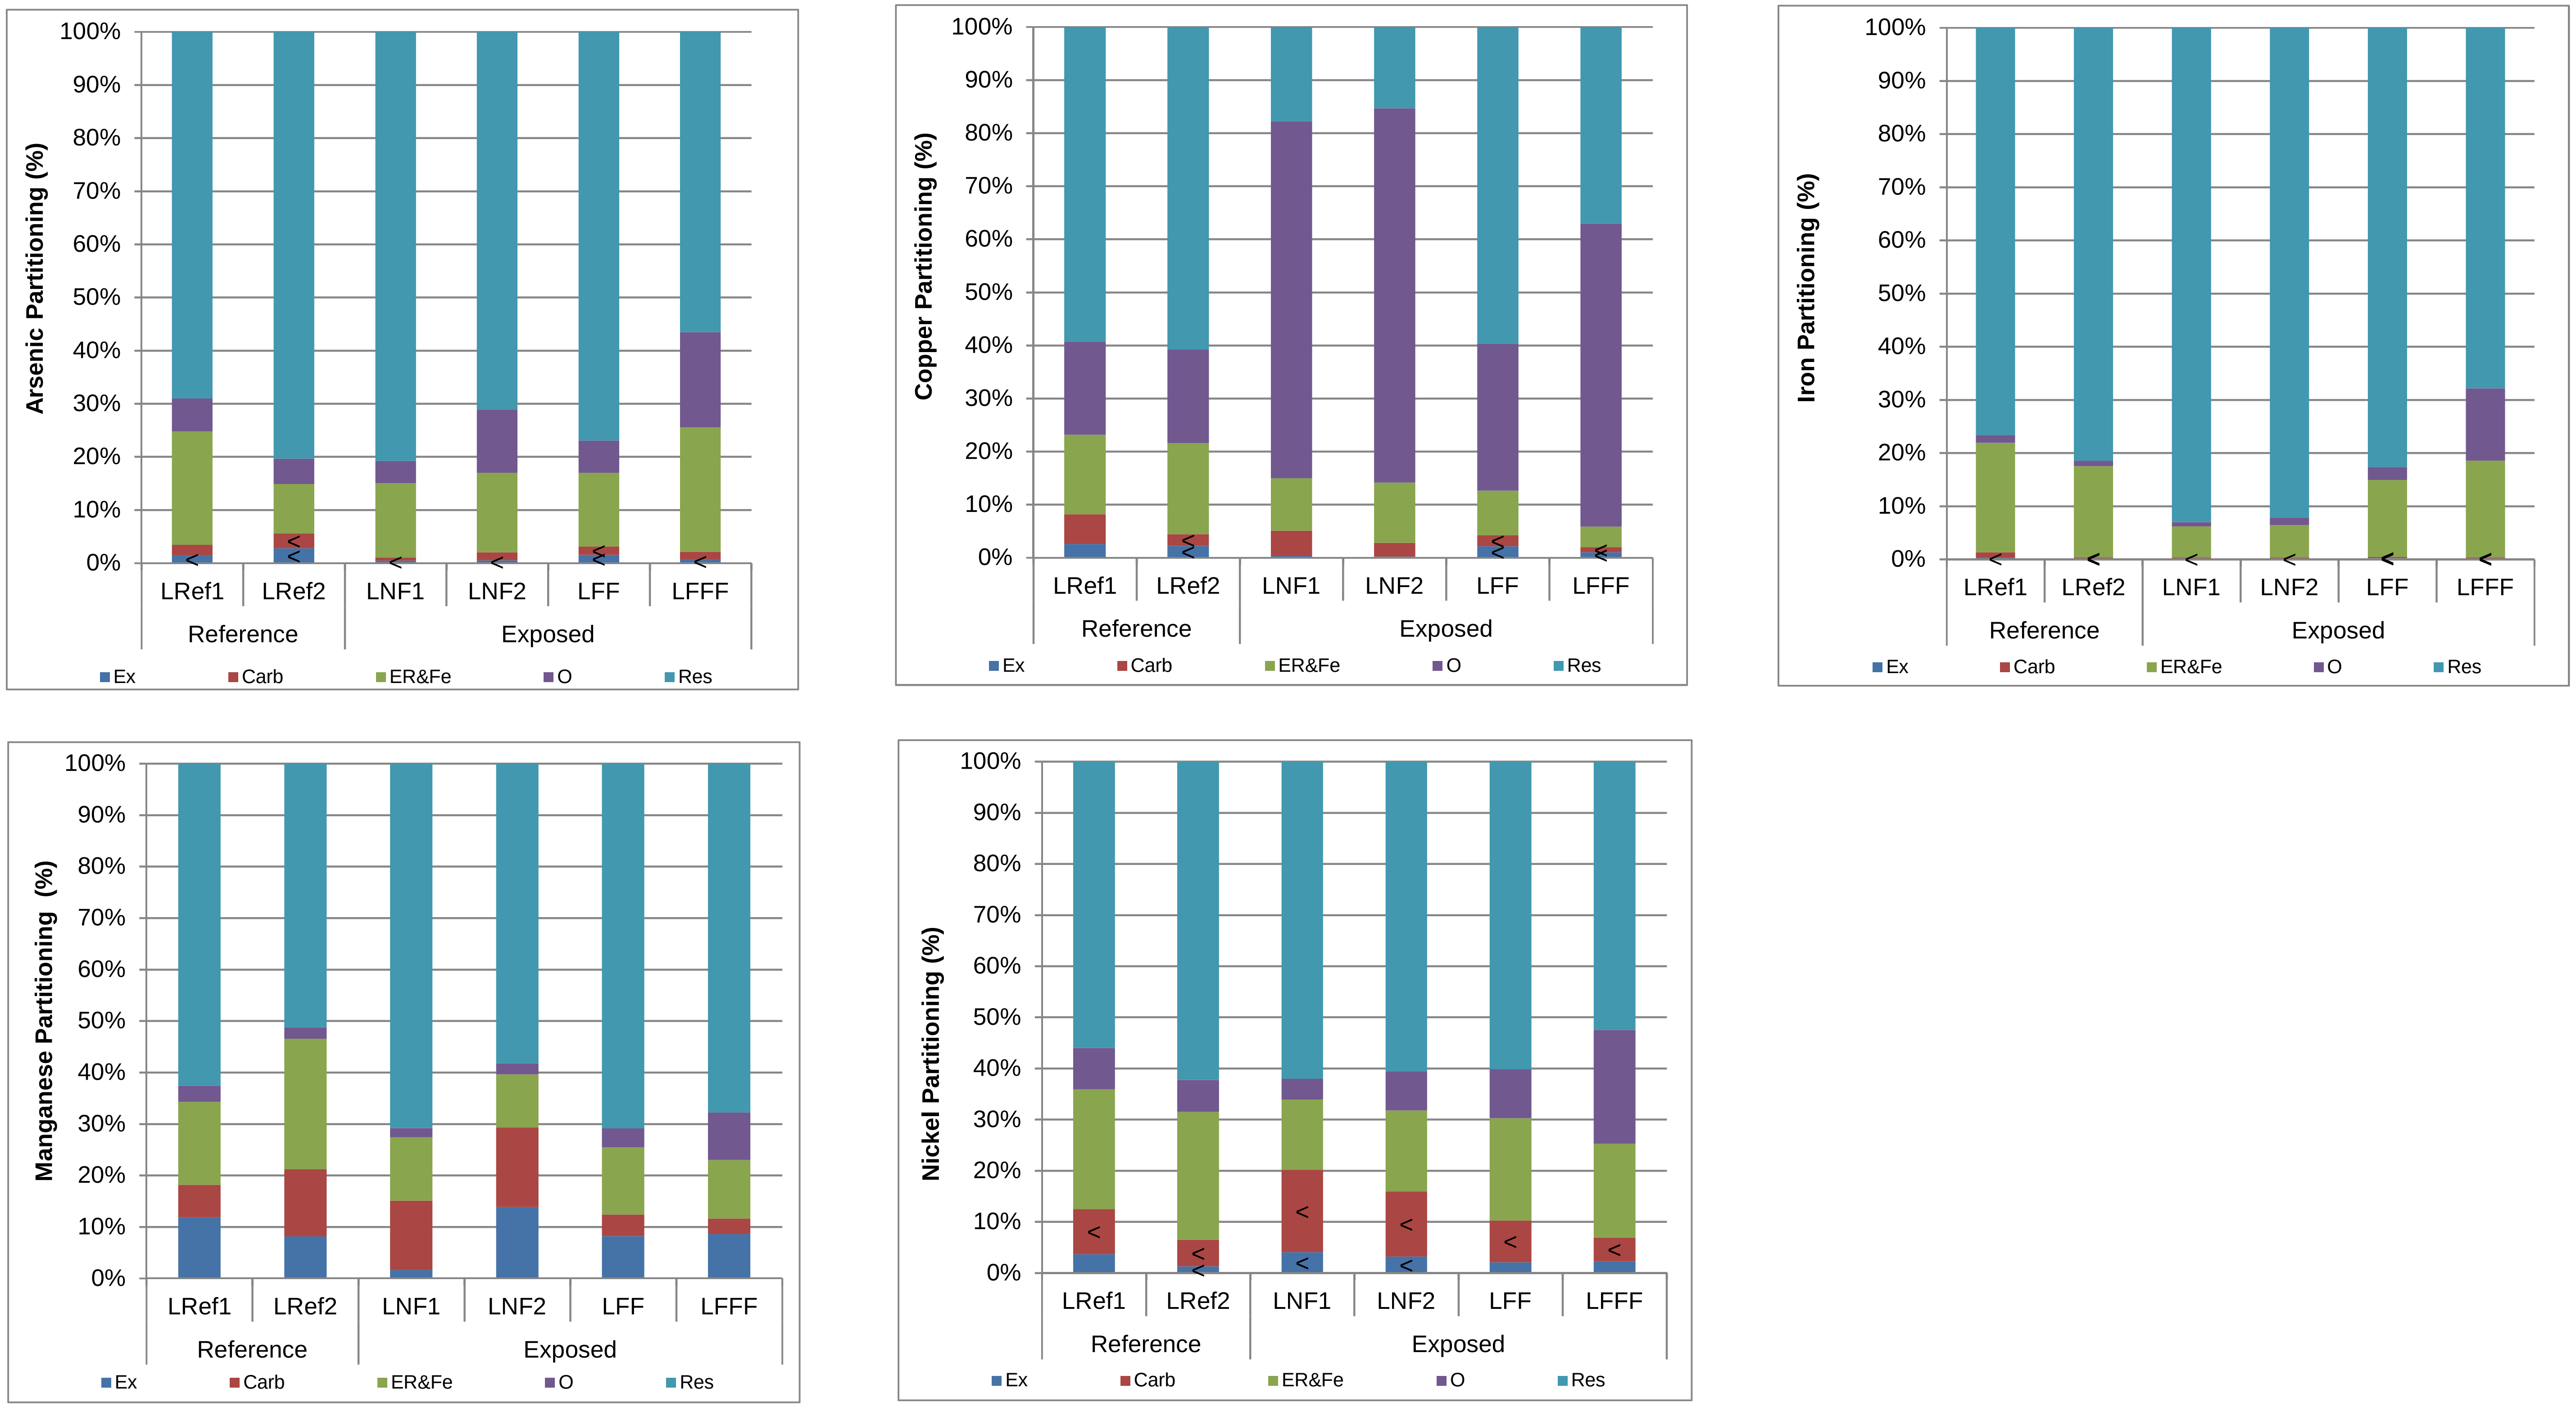

Figure E.27 (a): Partitioning of parameters of interest within selectively extracted fractions of sediment from the littoral sampling areas of Quesnel Lake, Mount Polley Mine, 2014. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic Bound Metals (O), and Residual Metals (Res).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL. Mean values are plotted for areas with replicate samples (LRef1, LNF1, LNF2), single values are plotted for composite samples (LRef2, LFF, LFFF).

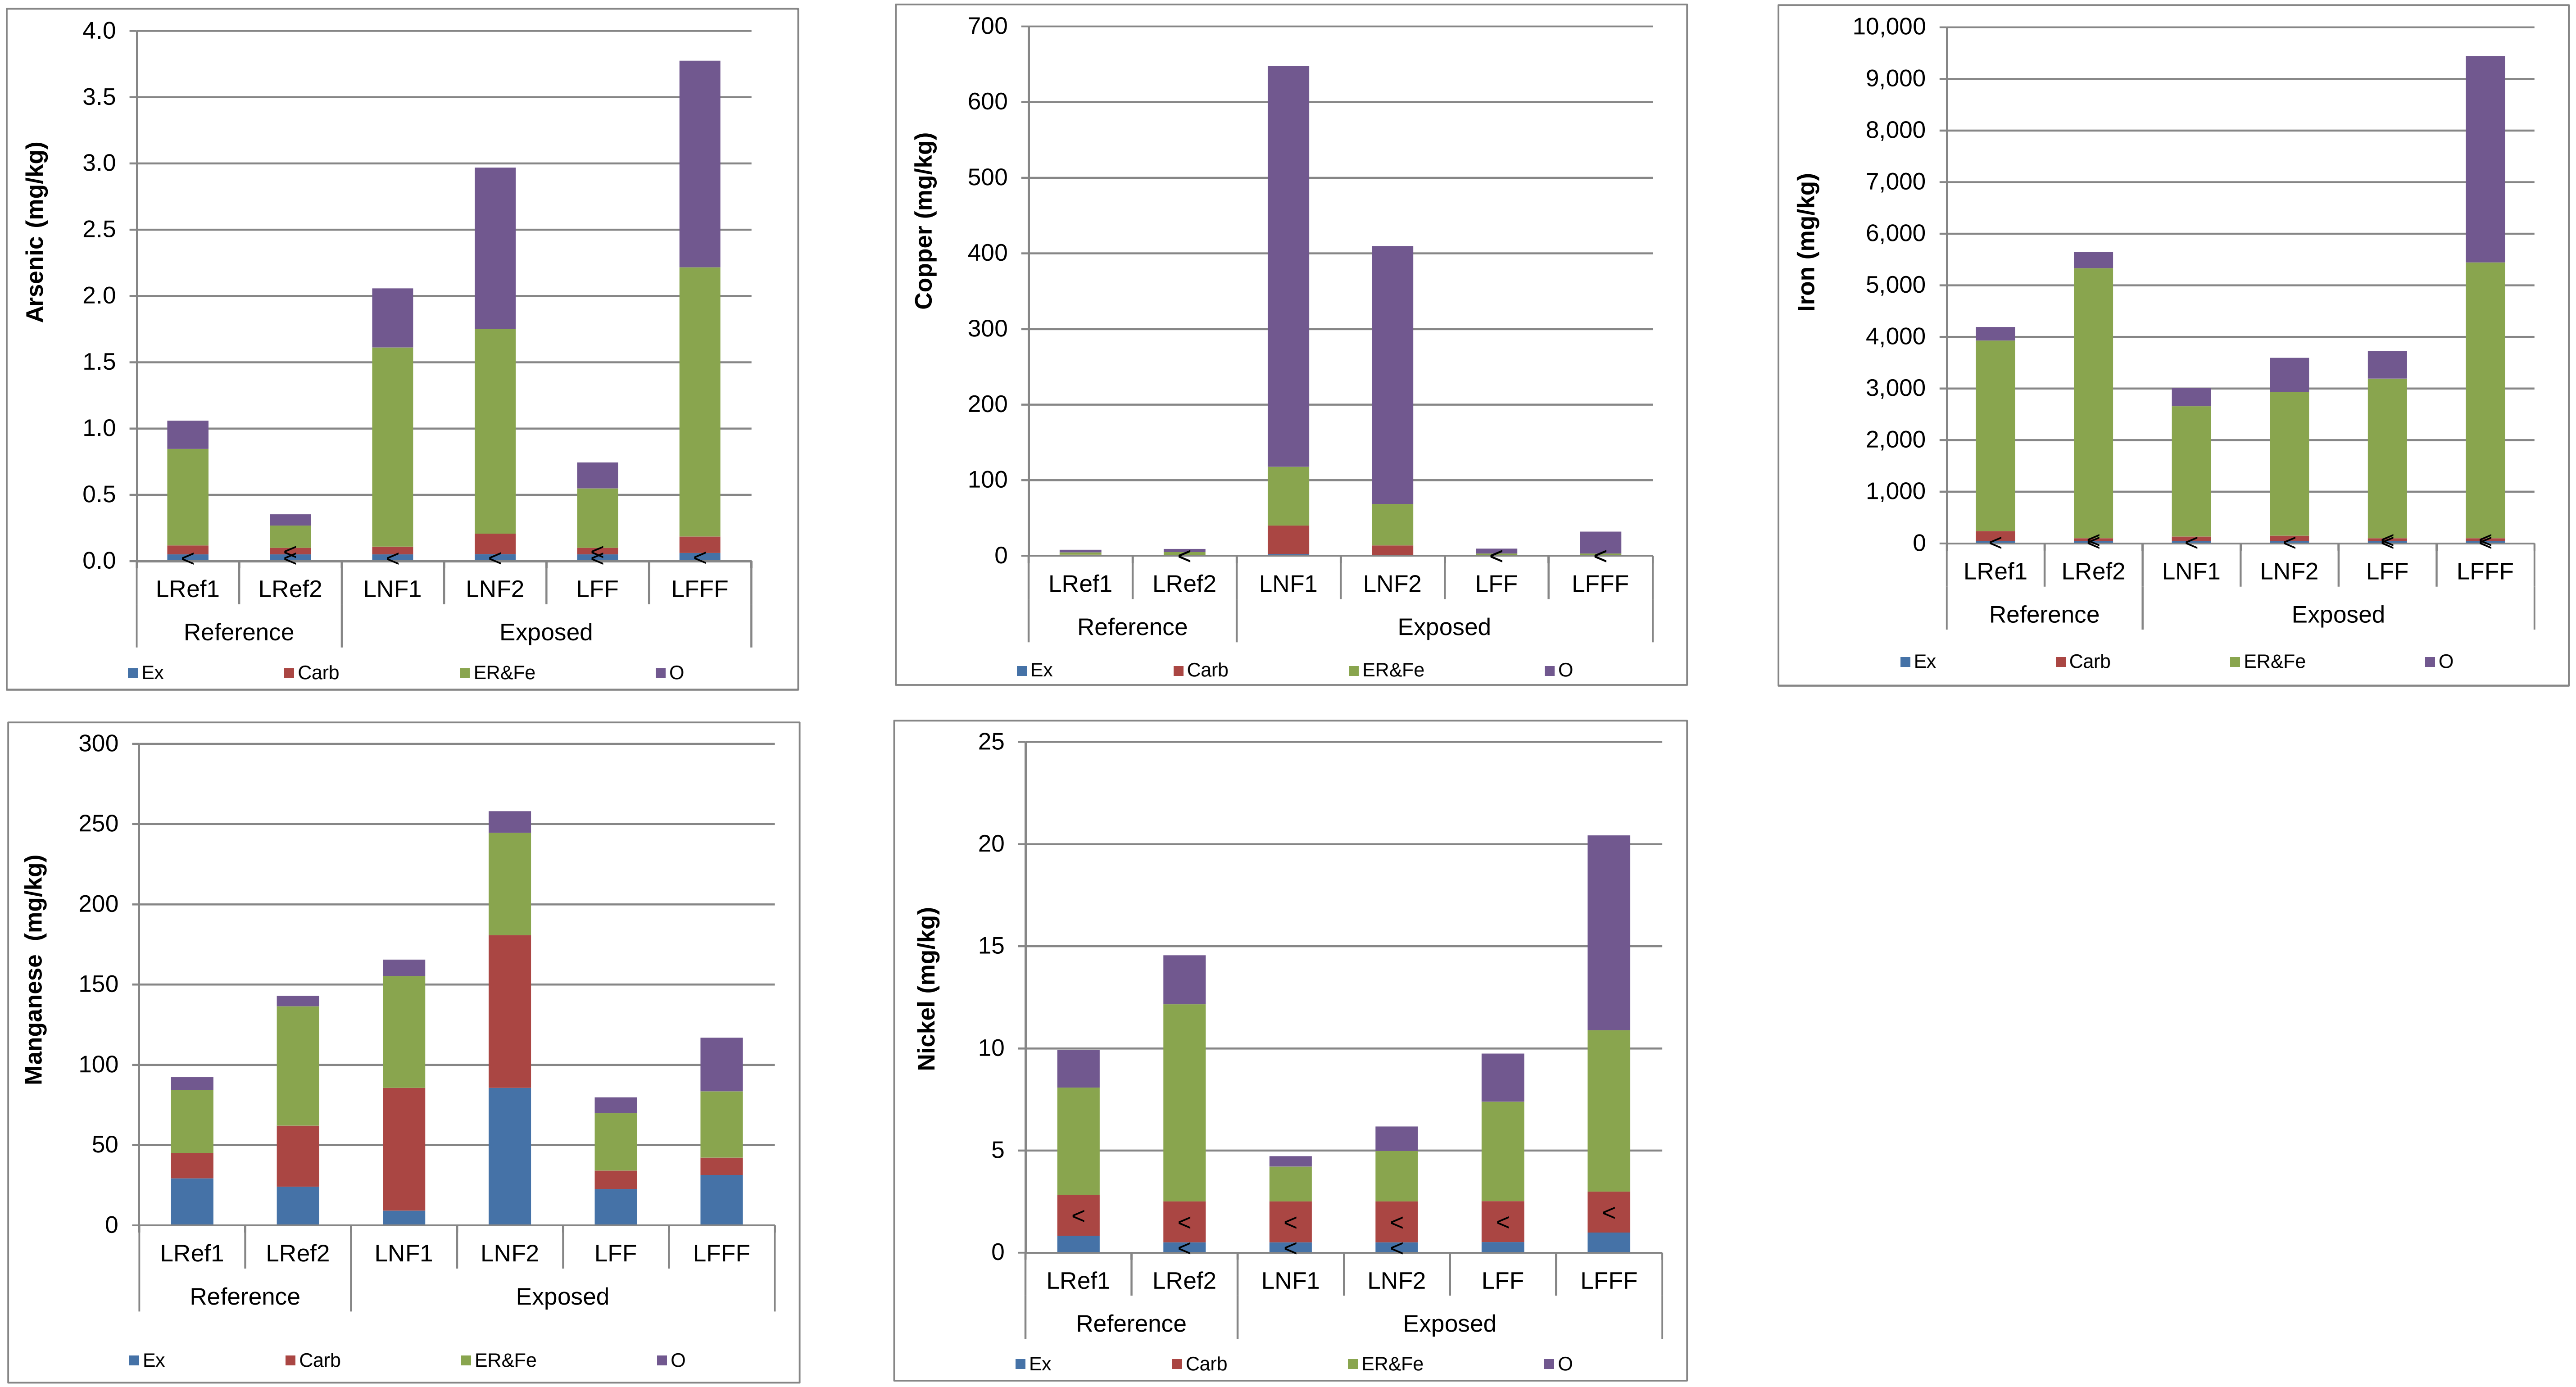

Figure E.27 (b): Mean concentrations of selectively extracted parameters of interest in sediment from the littoral sampling areas of Quesnel Lake, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) and Organic Bound Metals (O) fractions are shown (Residual metals are excluded).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL. Mean values are plotted for areas with replicate samples (LRef1, LNF1, LNF2), single values are plotted for composite samples (LRef2, LFF, LFFF).

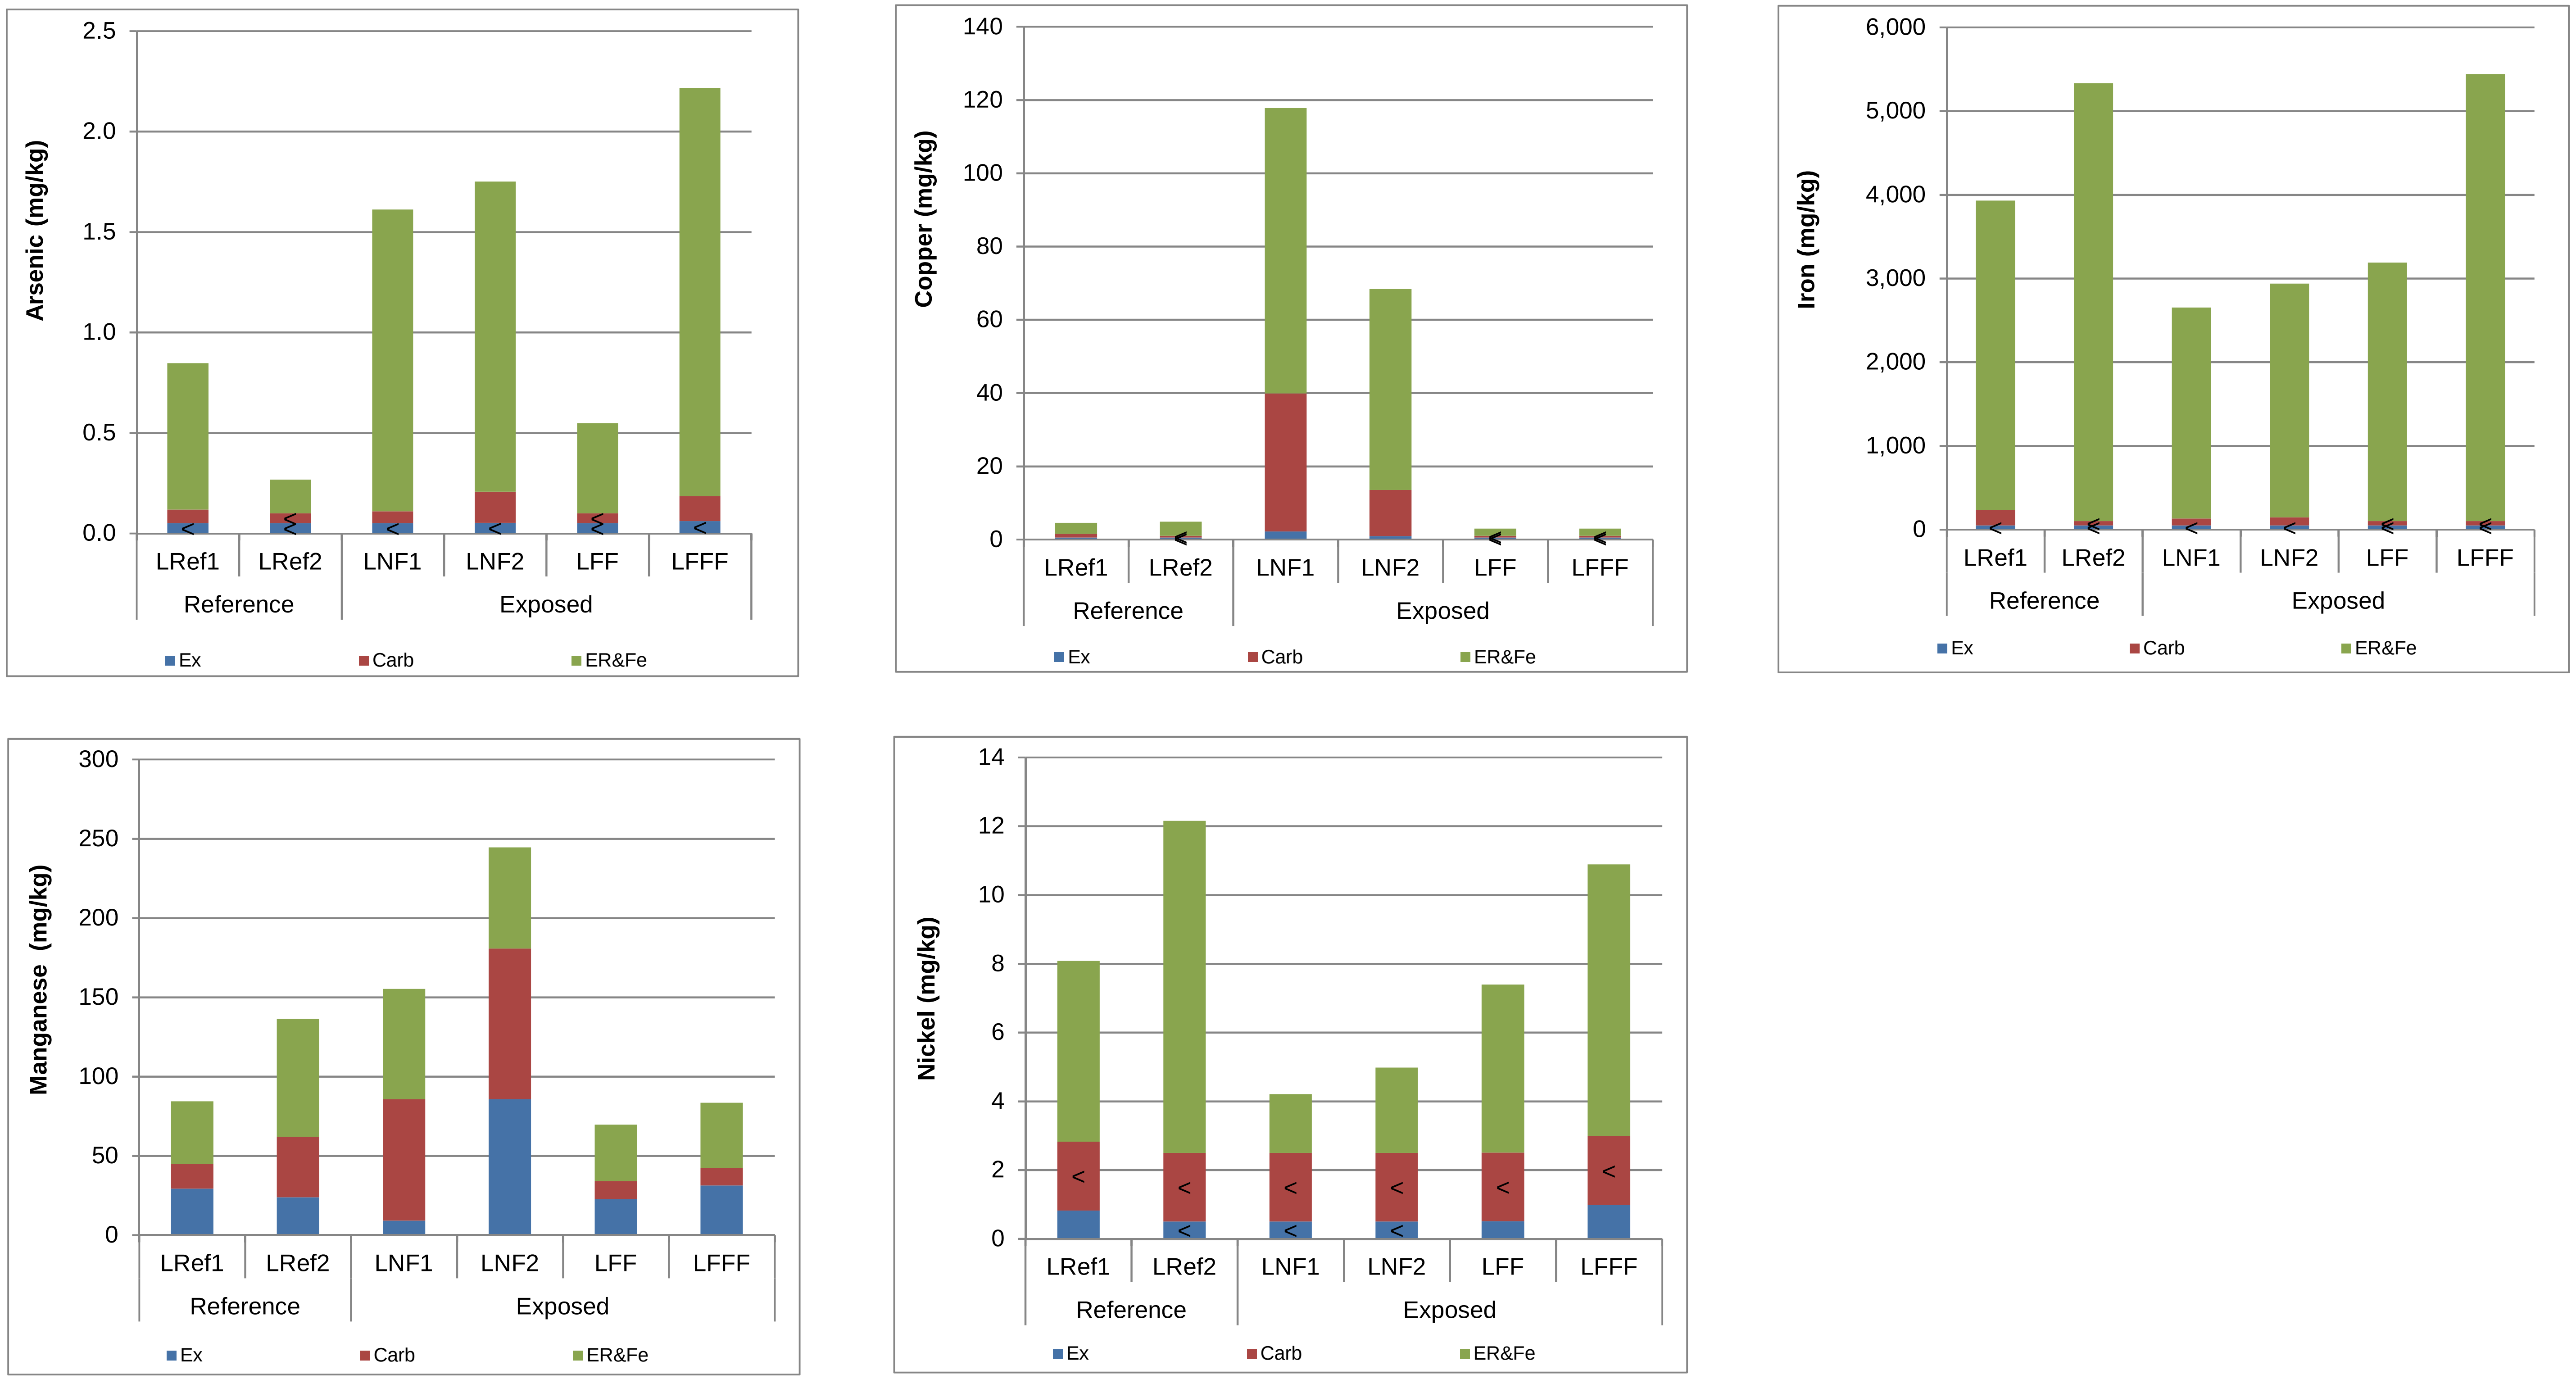

Figure E.27 (c): Mean concentrations of selectively extracted parameters of interest in sediment from the littoral sampling areas of Quesnel Lake, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) fractions are shown (Organic Bound and Residual metals are excluded).

Mean values < MDL are indicated with a < symbol. Means are reported as < MDL if all data used in their calculation were < MDL. Mean values are plotted for areas with replicate samples (LRef1, LNF1, LNF2), single values are plotted for composite samples (LRef2, LFF, LFFF).

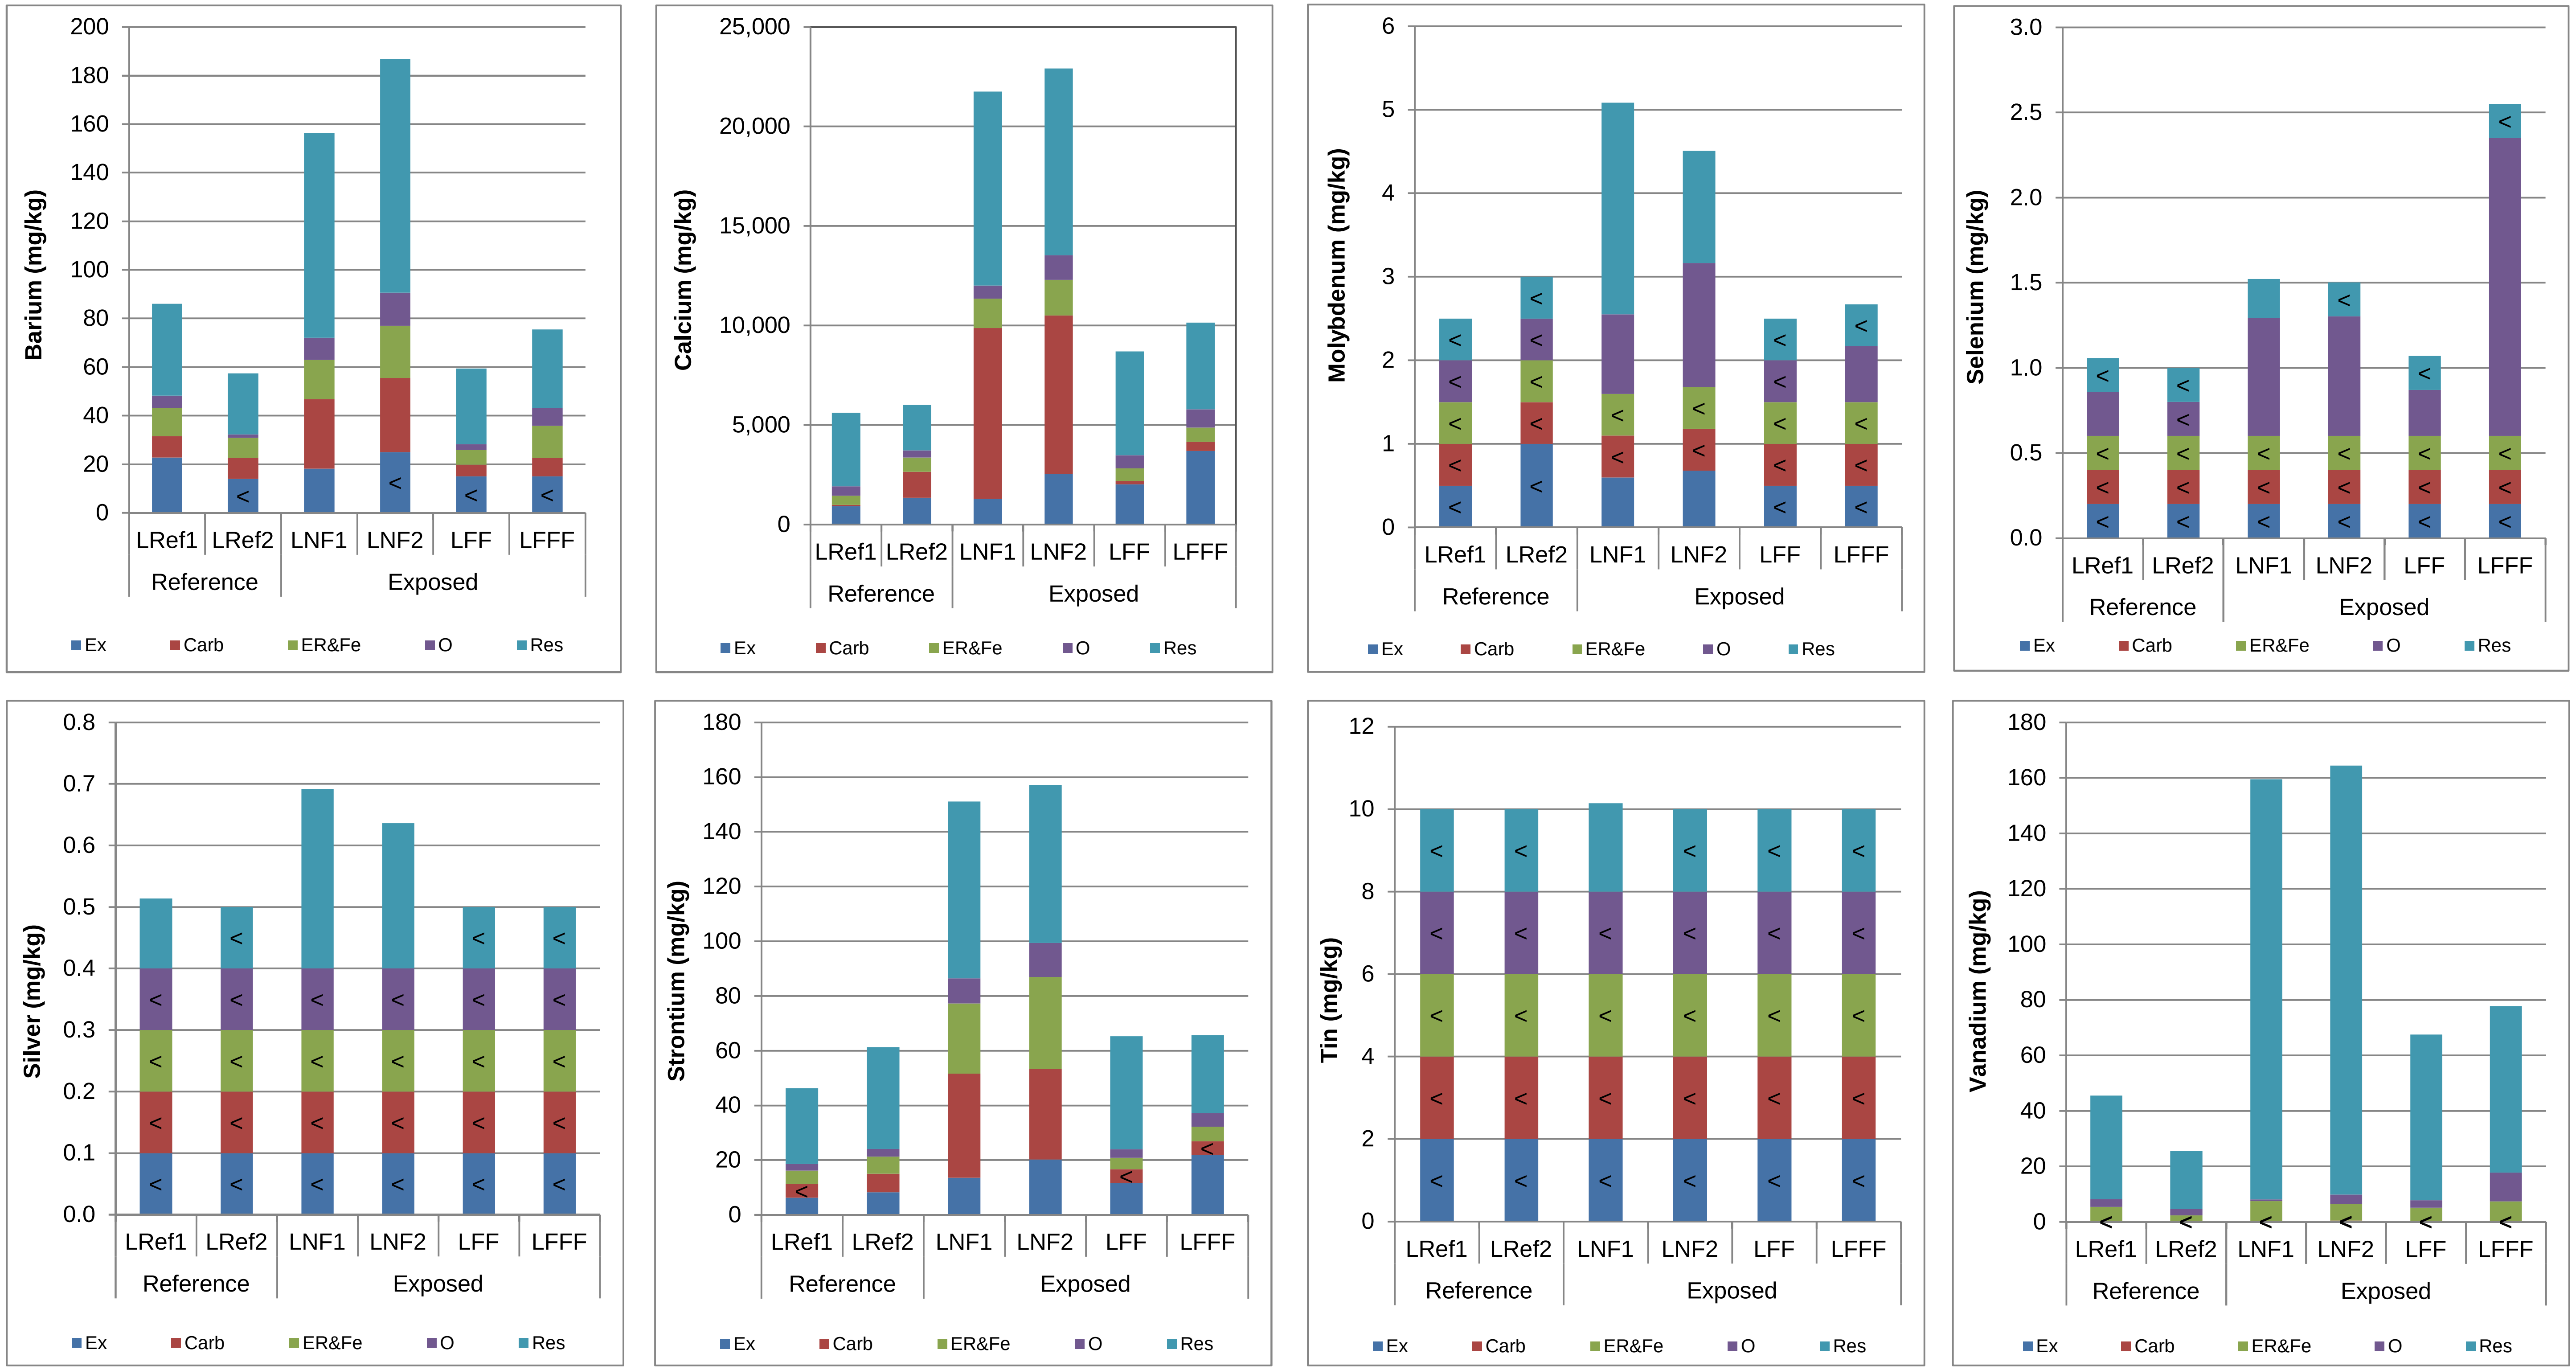

Figure E.28 (a): Mean concentrations of selectively extracted indicator parameters in sediment from the littoral sampling areas of Quesnel Lake, Mount Polley Mine, 2014. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic Bound Metals (O), and Residual Metals (Res).

Values < MDL are indicated with a < symbol. Mean values are plotted for areas with replicate samples (LRef1, LNF1, LNF2), single values are plotted for composite samples (LRef2, LFF, LFFF). Data for mercury were not available, sodium data were available only for the Exchangeable & Adsorbed Metals fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result.

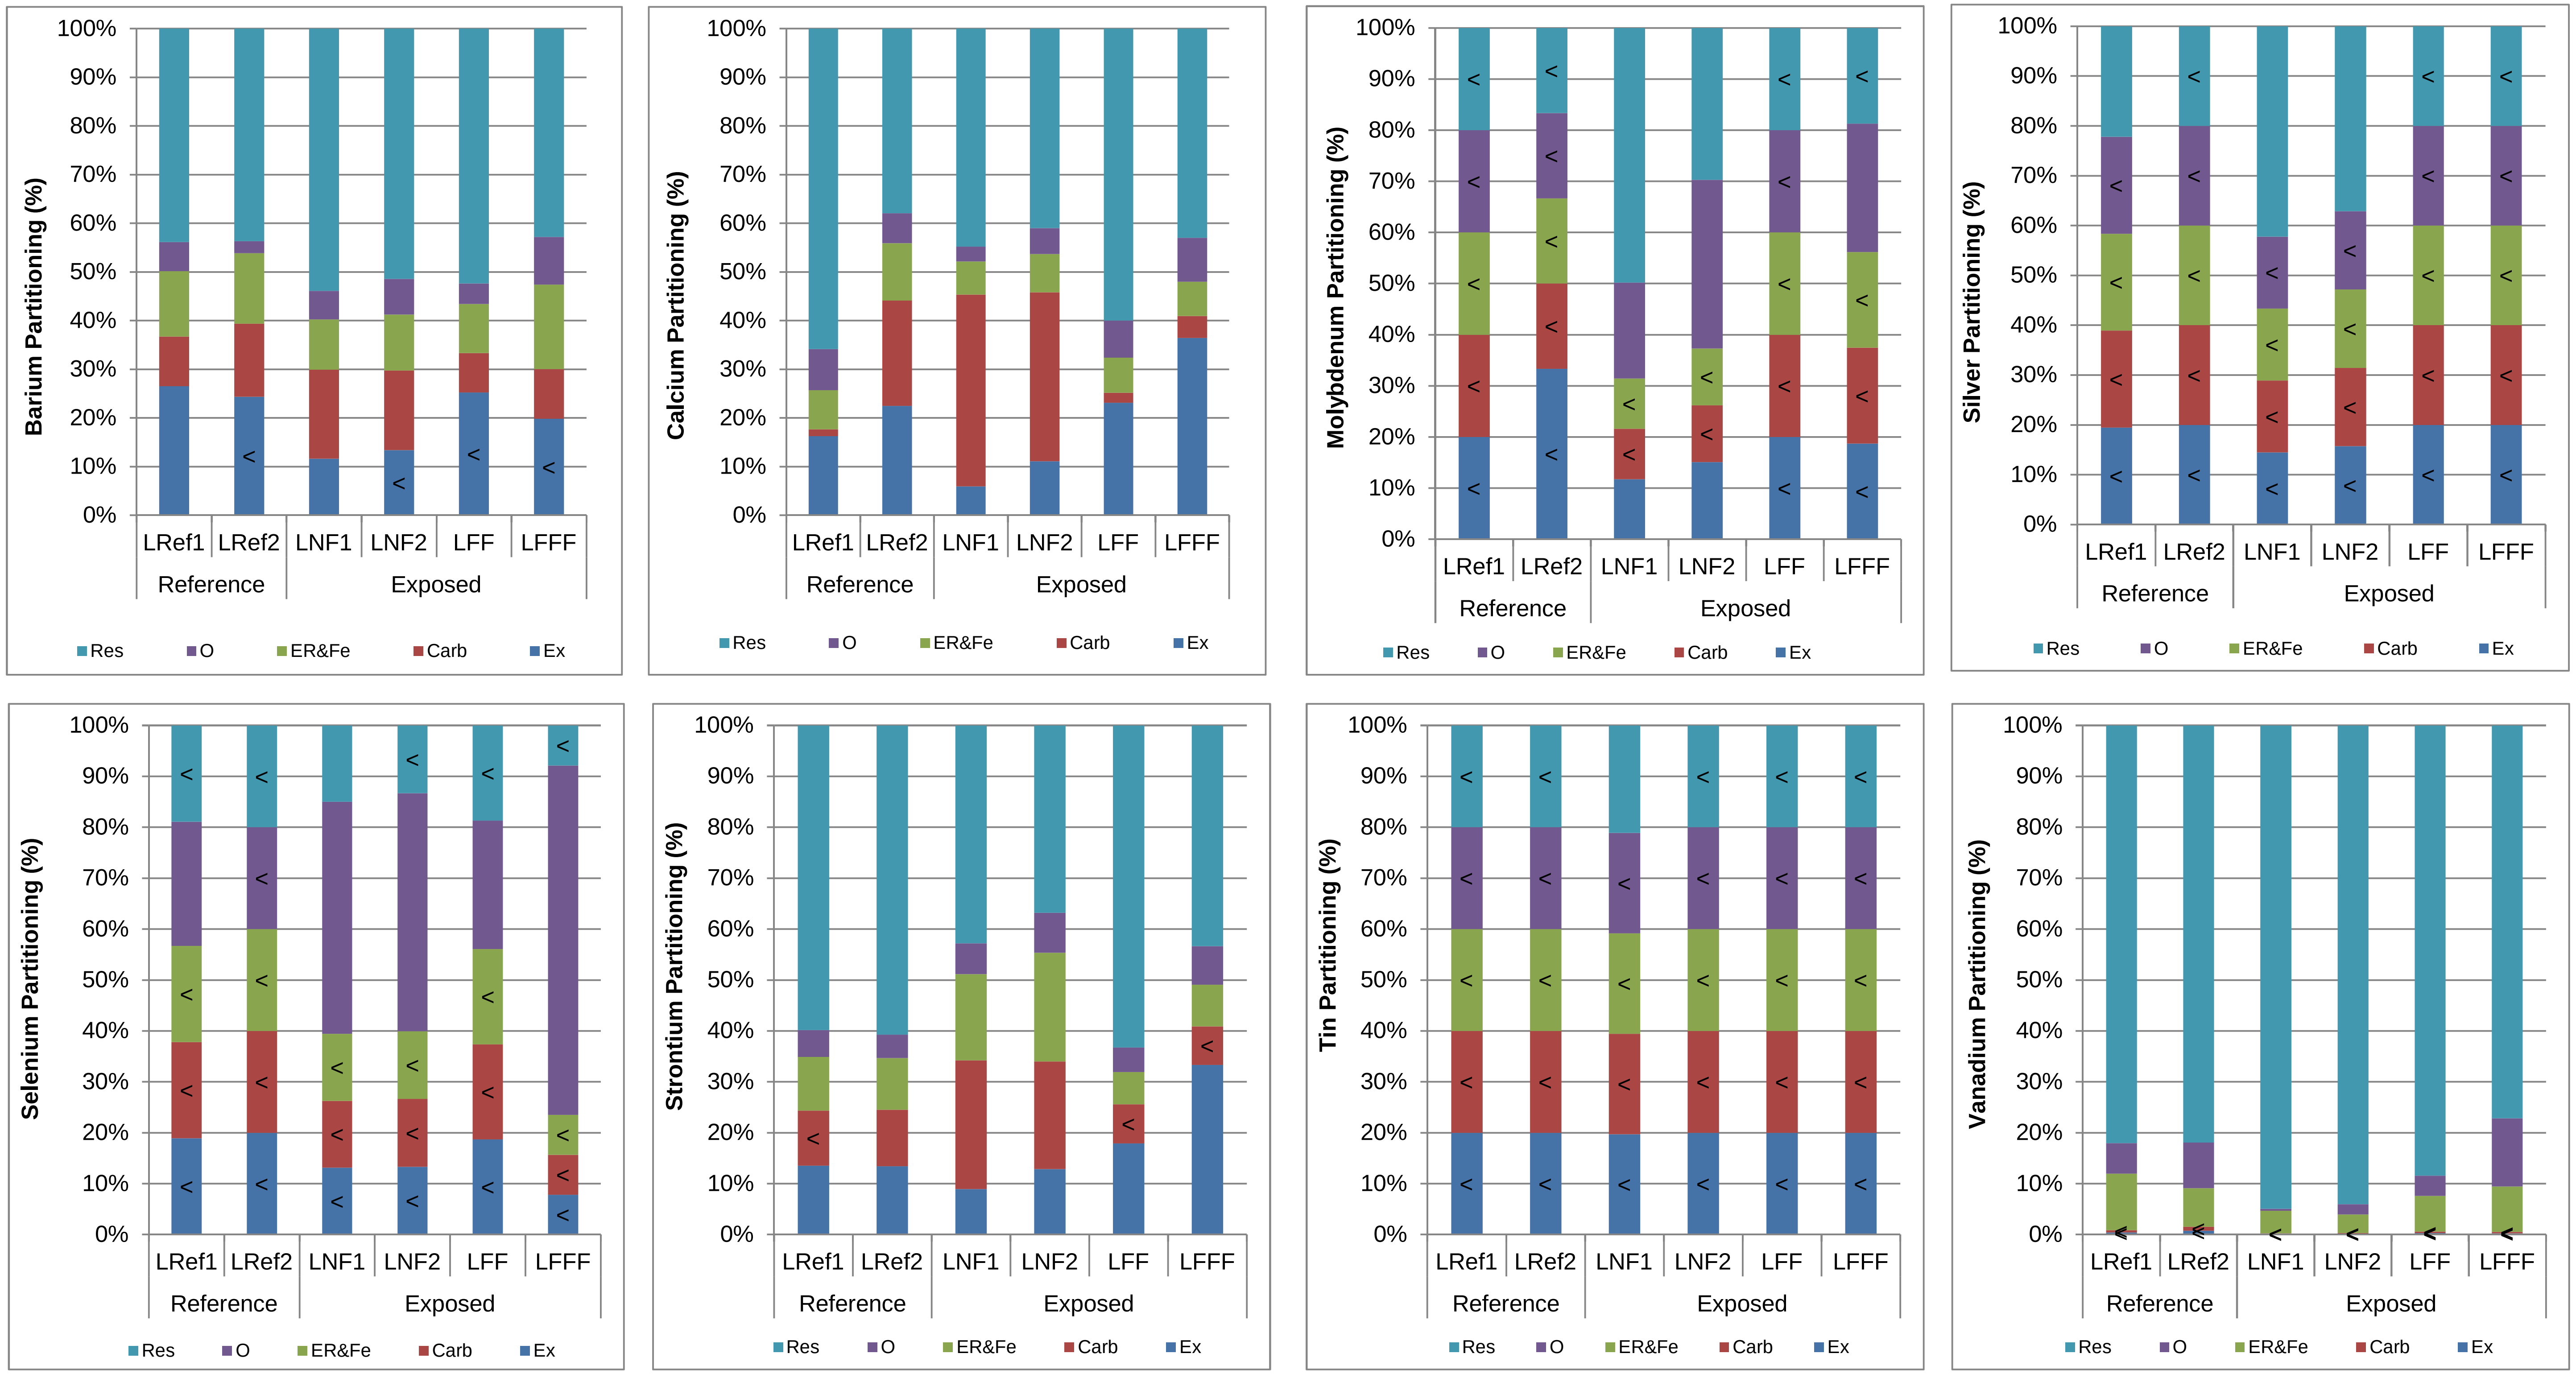

Figure E.28 (b): Partitioning of indicator parameters within selectively extracted fractions of sediment from the littoral sampling areas of Quesnel Lake, Mount Polley Mine, 2014. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic Bound Metals (O), and Residual Metals (Res).

Values < MDL are indicated with a < symbol. Mean values are plotted for areas with replicate samples (LRef1, LNF1, LNF2), single values are plotted for composite samples (LRef2, LFF, LFFF). Data for mercury were not available, sodium data were available only for the Exchangeable & Adsorbed Metals fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result.

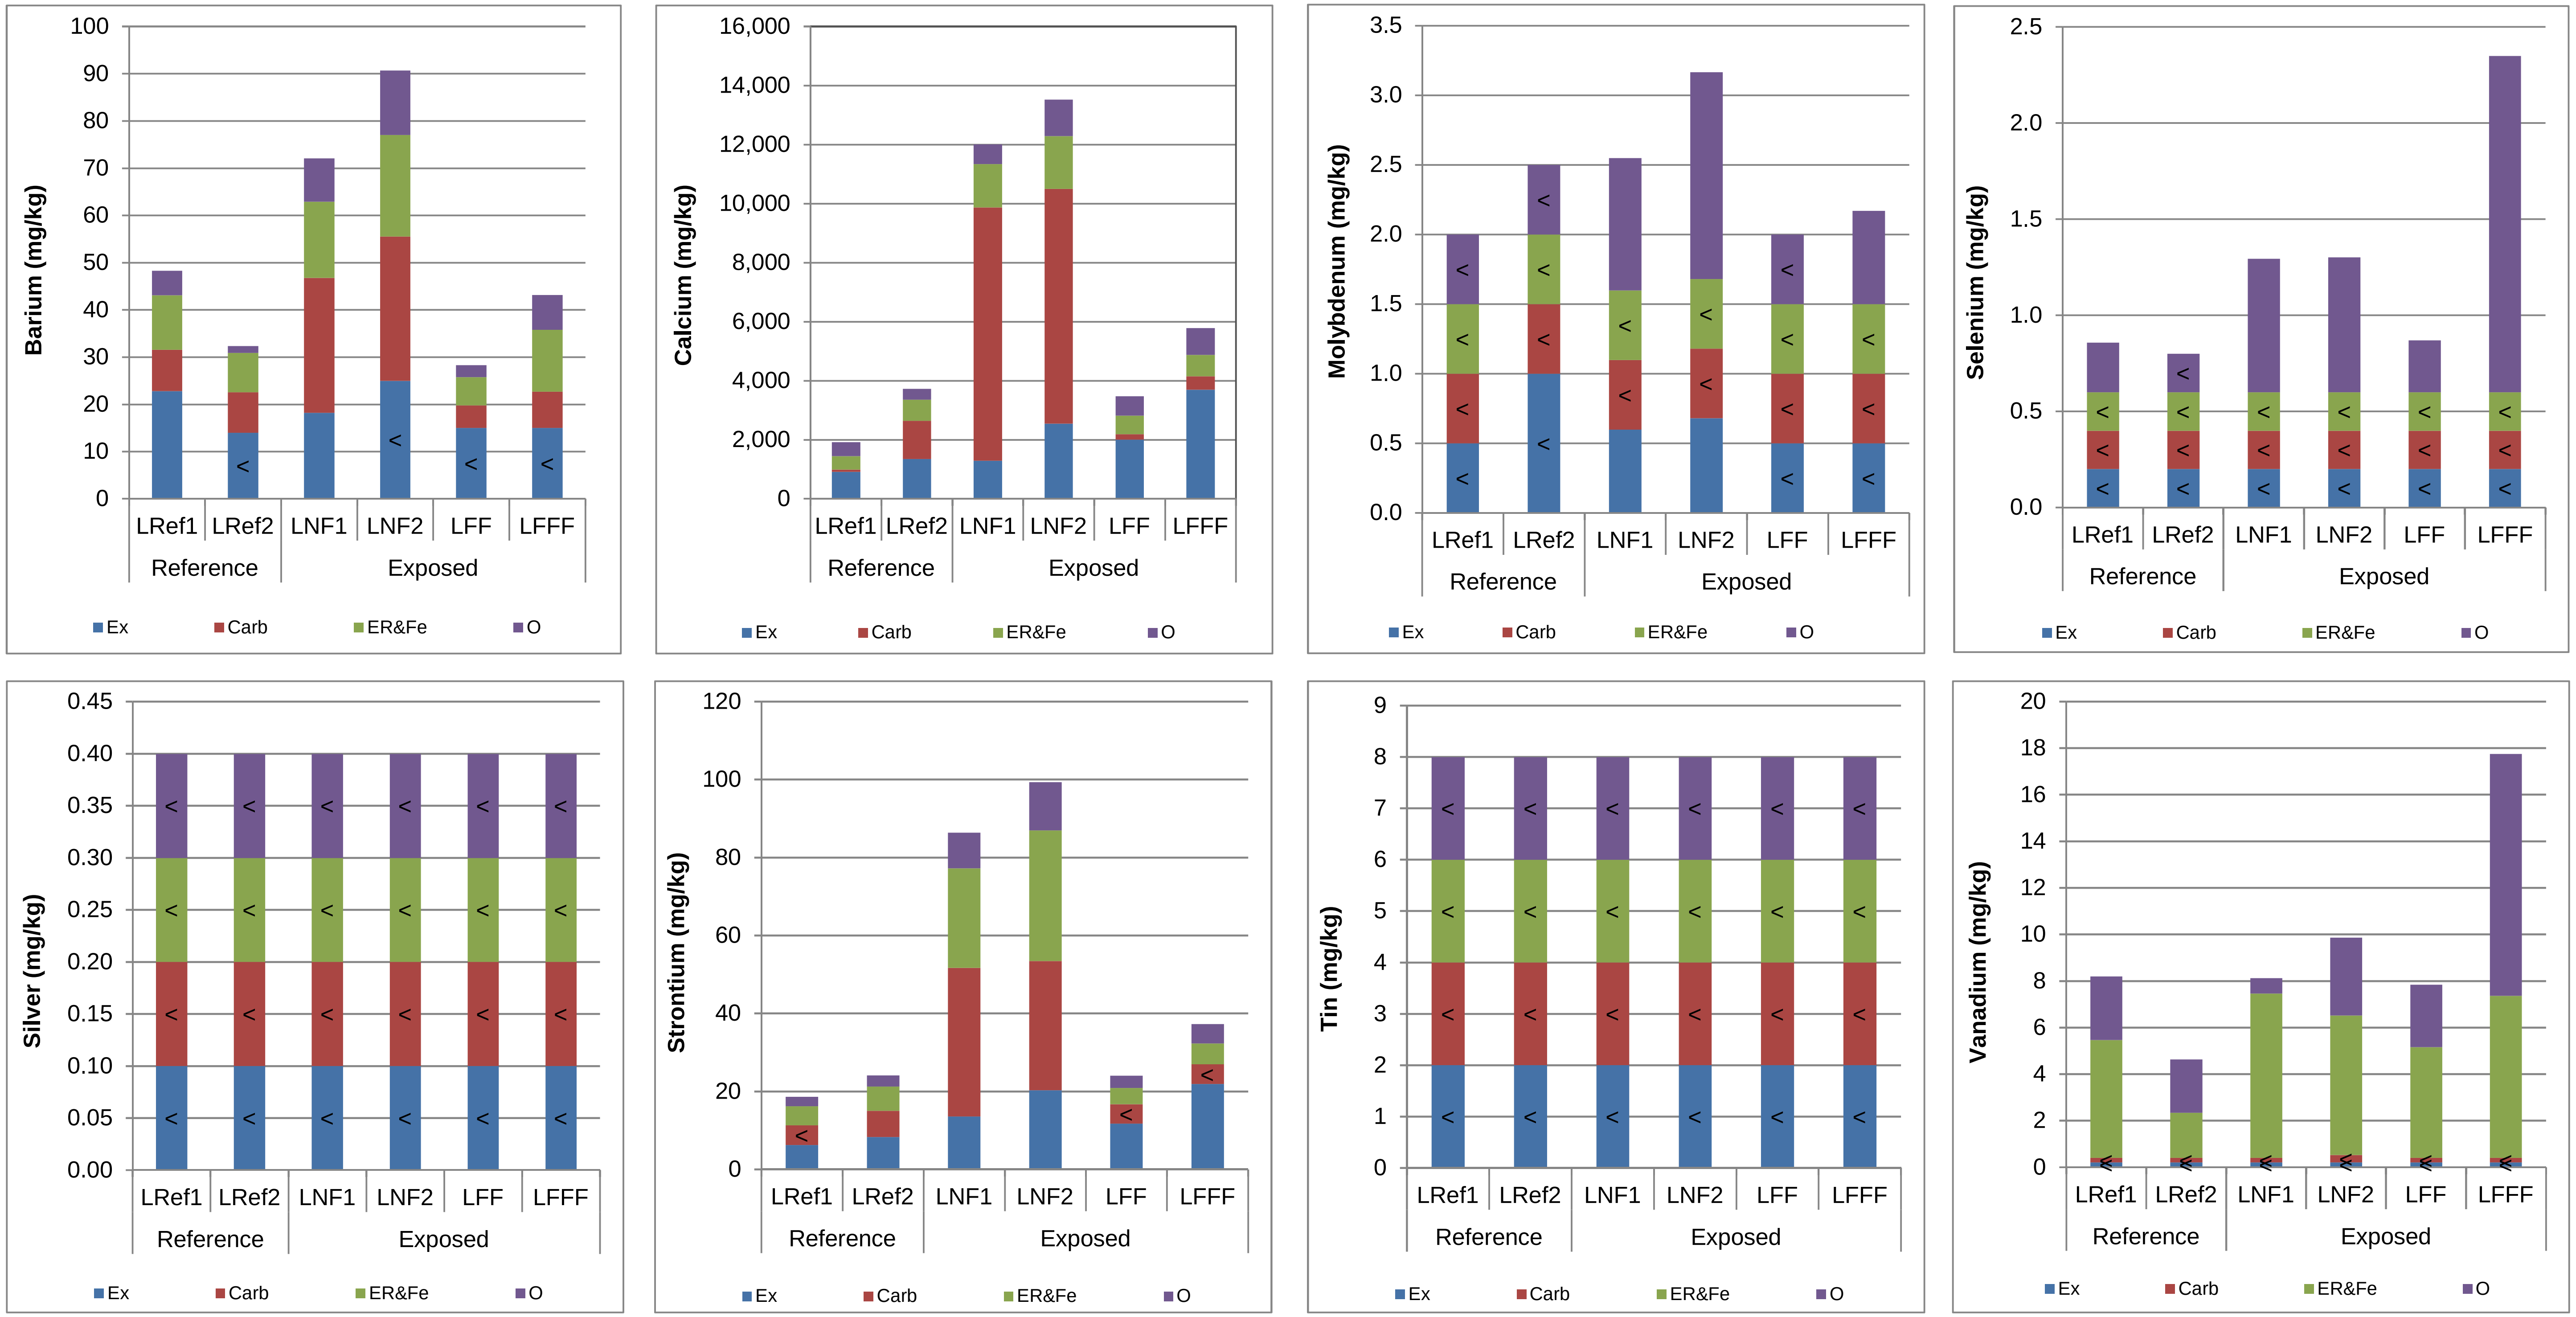

Figure E.28 (c): Mean concentrations of selectively extracted indicator parameters in sediment from the littoral sampling areas of Quesnel Lake, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) and Organic Bound Metals (O) fractions are shown (Residual metals are excluded).

Values < MDL are indicated with a < symbol. Mean values are plotted for areas with replicate samples (LRef1, LNF1, LNF2), single values are plotted for composite samples (LRef2, LFF, LFFF). Data for mercury were not available, sodium data were available only for the Exchangeable & Adsorbed Metals fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result.

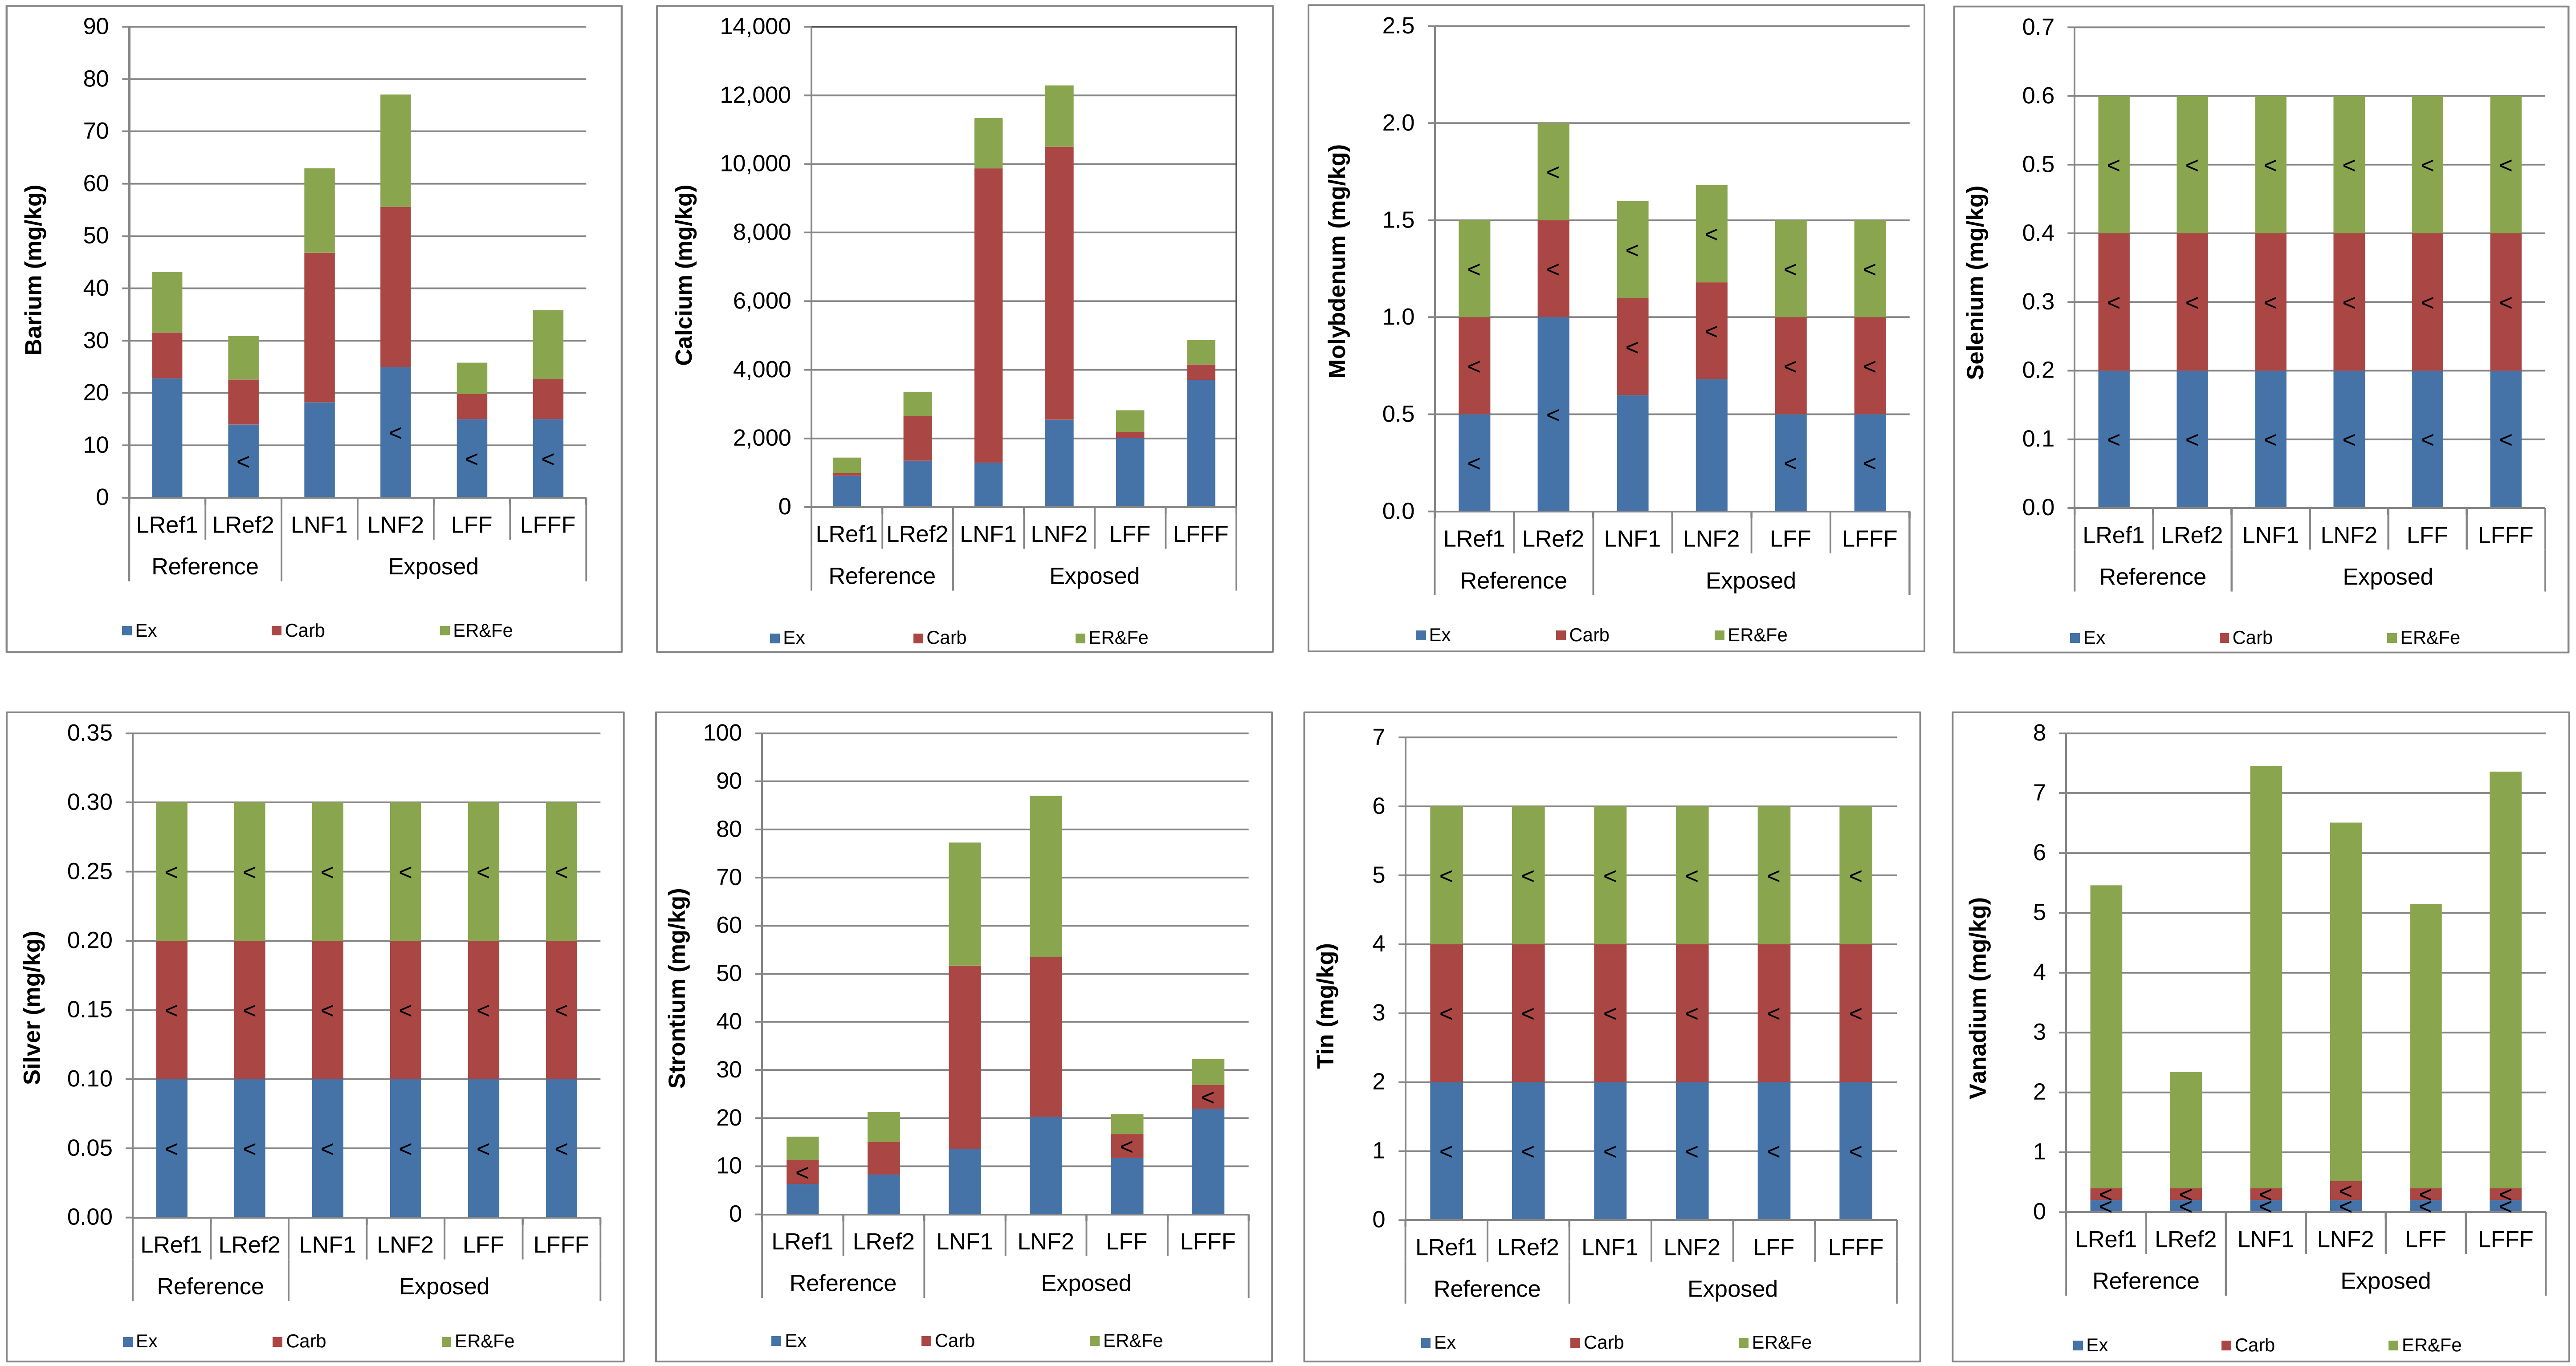

Figure E.28 (d): Mean concentrations of selectively extracted indicator parameters in sediment from the littoral sampling areas of Quesnel Lake, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) fractions are shown (Organic Bound and Residual metals are excluded).

Values < MDL are indicated with a < symbol. Mean values are plotted for areas with replicate samples (LRef1, LNF1, LNF2), single values are plotted for composite samples (LRef2, LFF, LFFF). Data for mercury were not available, sodium data were available only for the Exchangeable & Adsorbed Metals fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result.

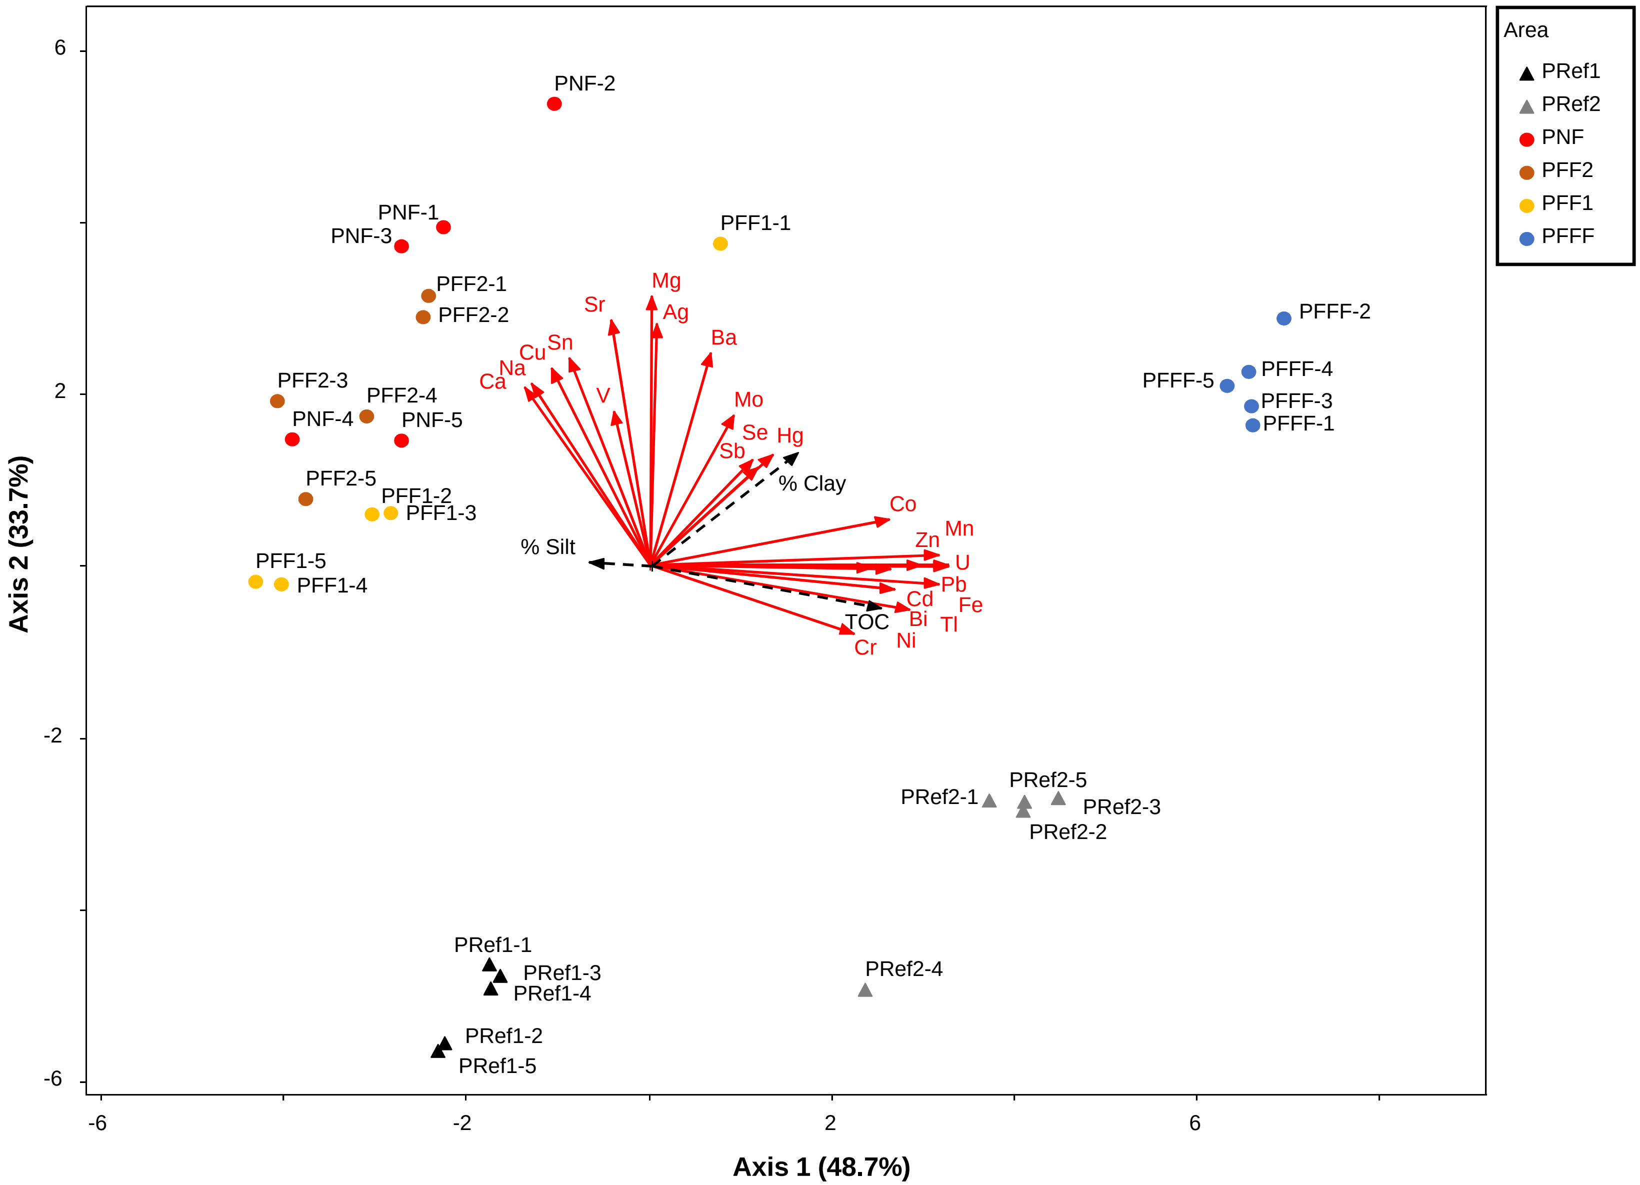

Figure E.29: Biplot of principal component analysis (PCA) of metal concentrations in sediment (<63 µm fraction) from Quesnel Lake profundal sampling stations, Mount Polley Mine, 2014. Vector length is proportional to the magnitude of direct correlation of metals (solid red vector lines) and indirect correlation of sediment physical characteristics (black dashed vector lines) with PCA values of each axis (Appendix Tables E.58-E.59). Only metals with significant (p-value <0.010) Spearman's correlation and r-values > 0.7 with either axis are displayed, all sediment physical characteristics are displayed.

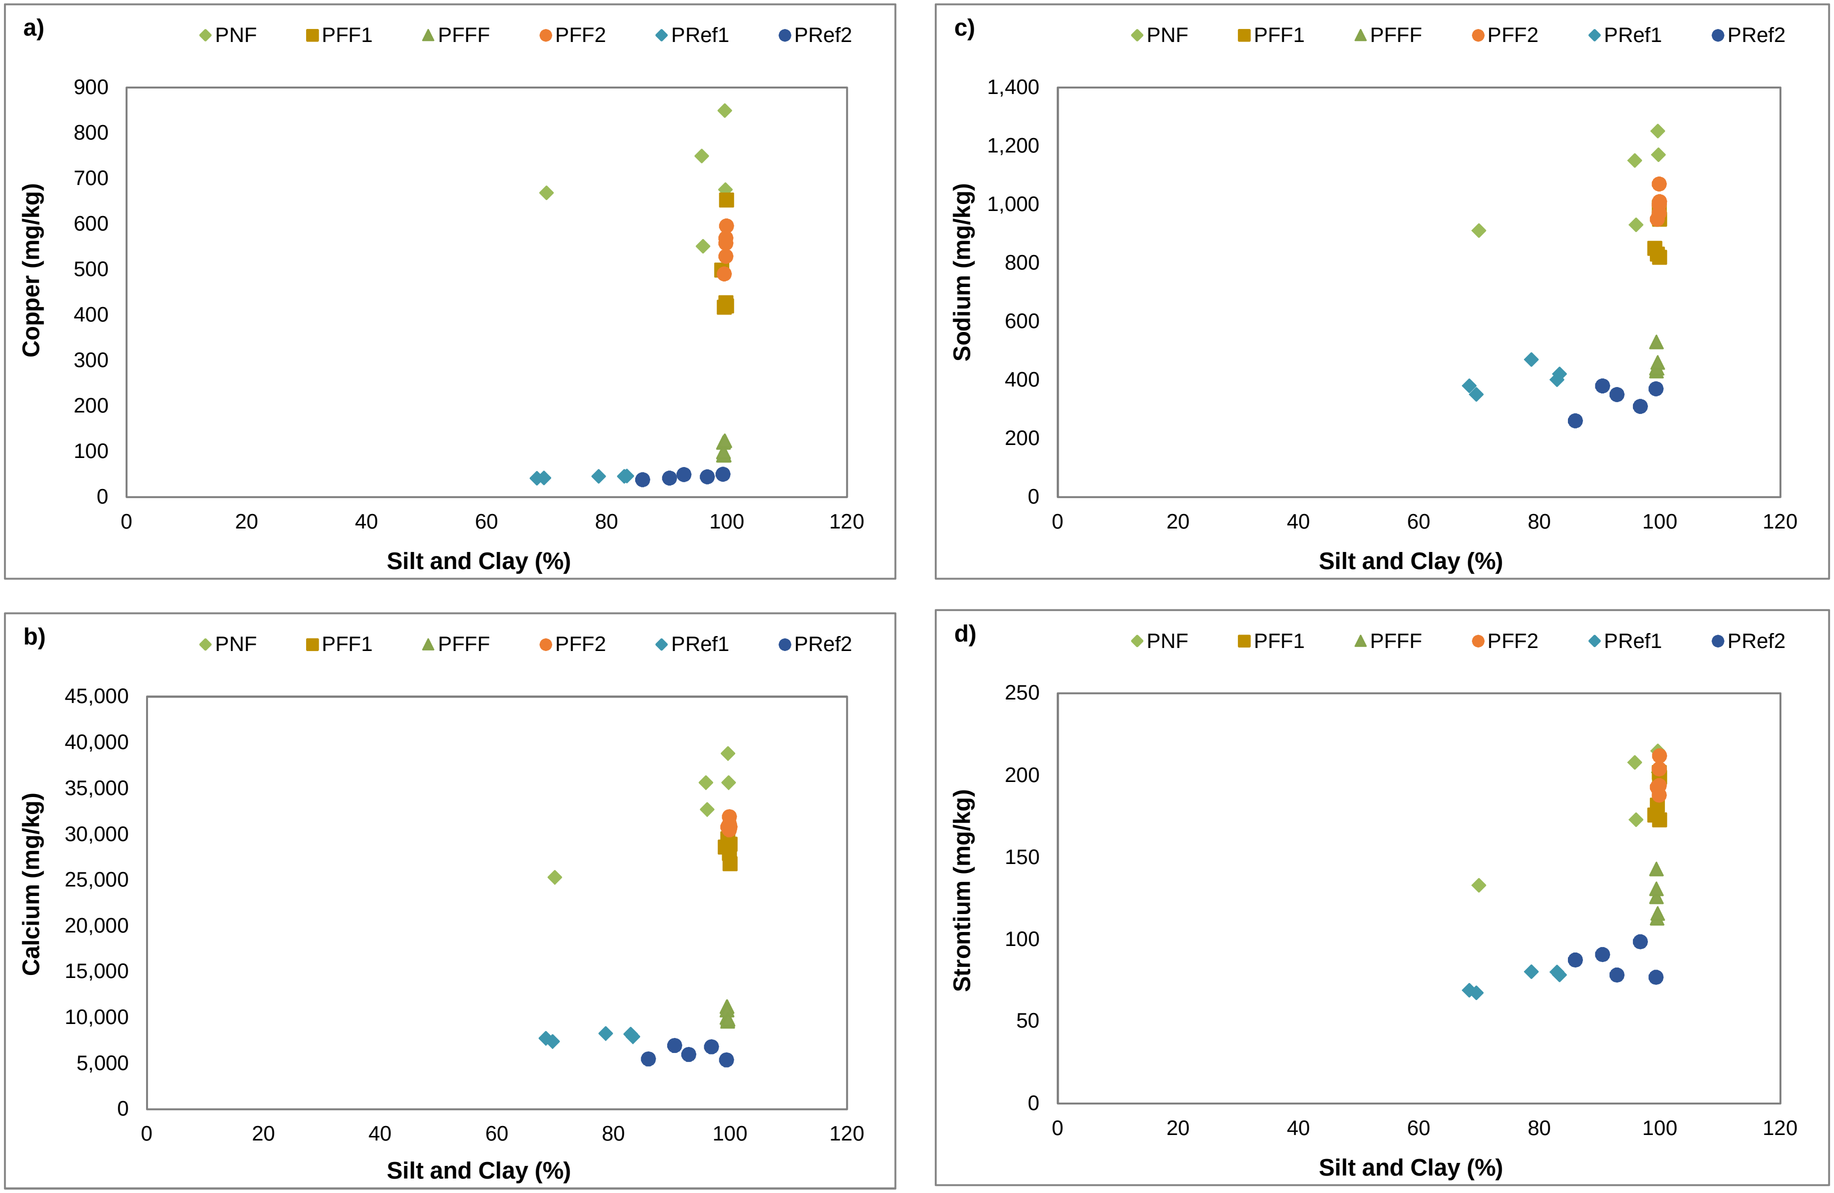

Figure E.30: Scatterplots of significant Spearman's correlation relationships ($p < 0.003$) between silt and clay (%) or total organic carbon (%), and parameters of interest or indicator parameters, Mount Polley Mine, 2014. Quesnel Lake profundal sampling areas. Hollow symbols indicate values < MDL.

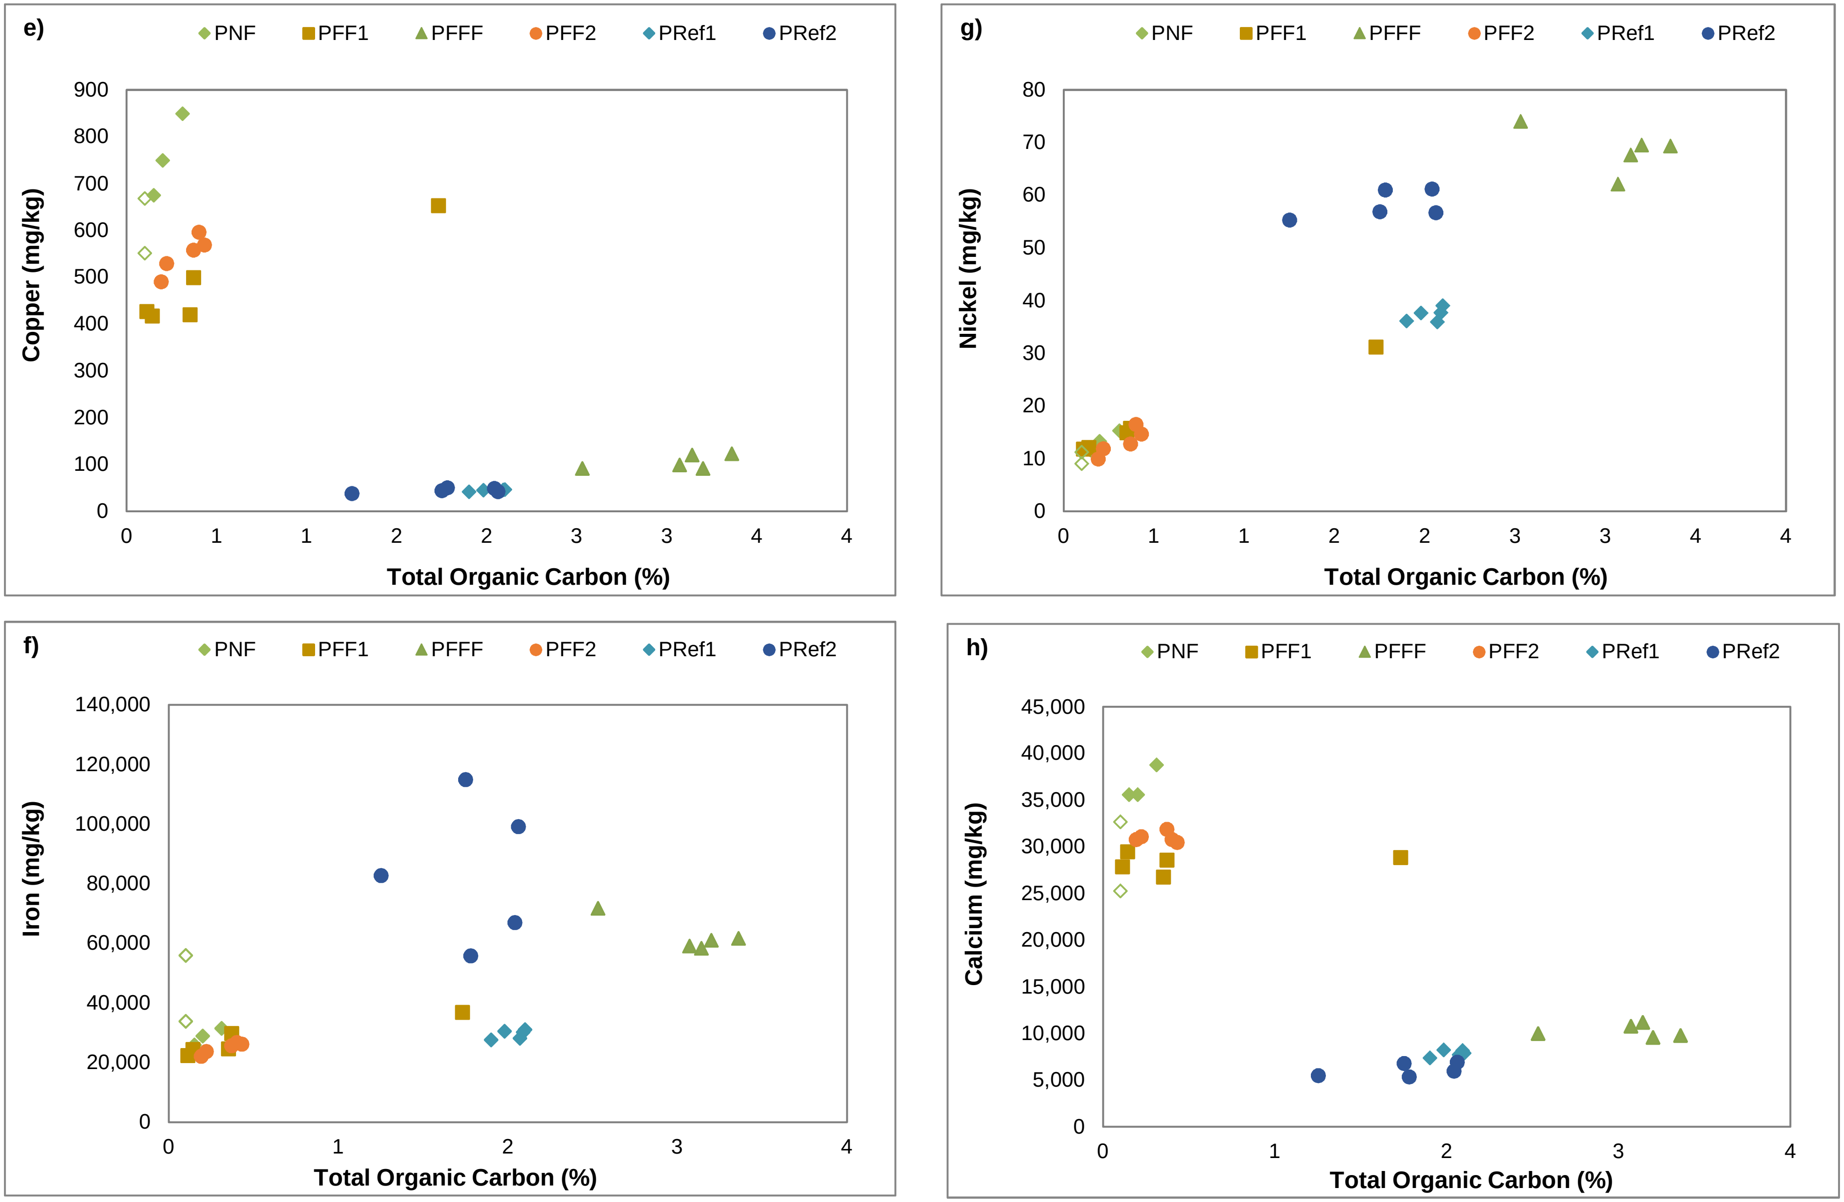

Figure E.30: Scatterplots of significant Spearman's correlation relationships (p < 0.003) between silt and clay (%) or total organic carbon (%), and parameters of interest or indicator parameters, Mount Polley Mine, 2014. Quesnel Lake profundal sampling areas. Hollow symbols indicate values < MDL.

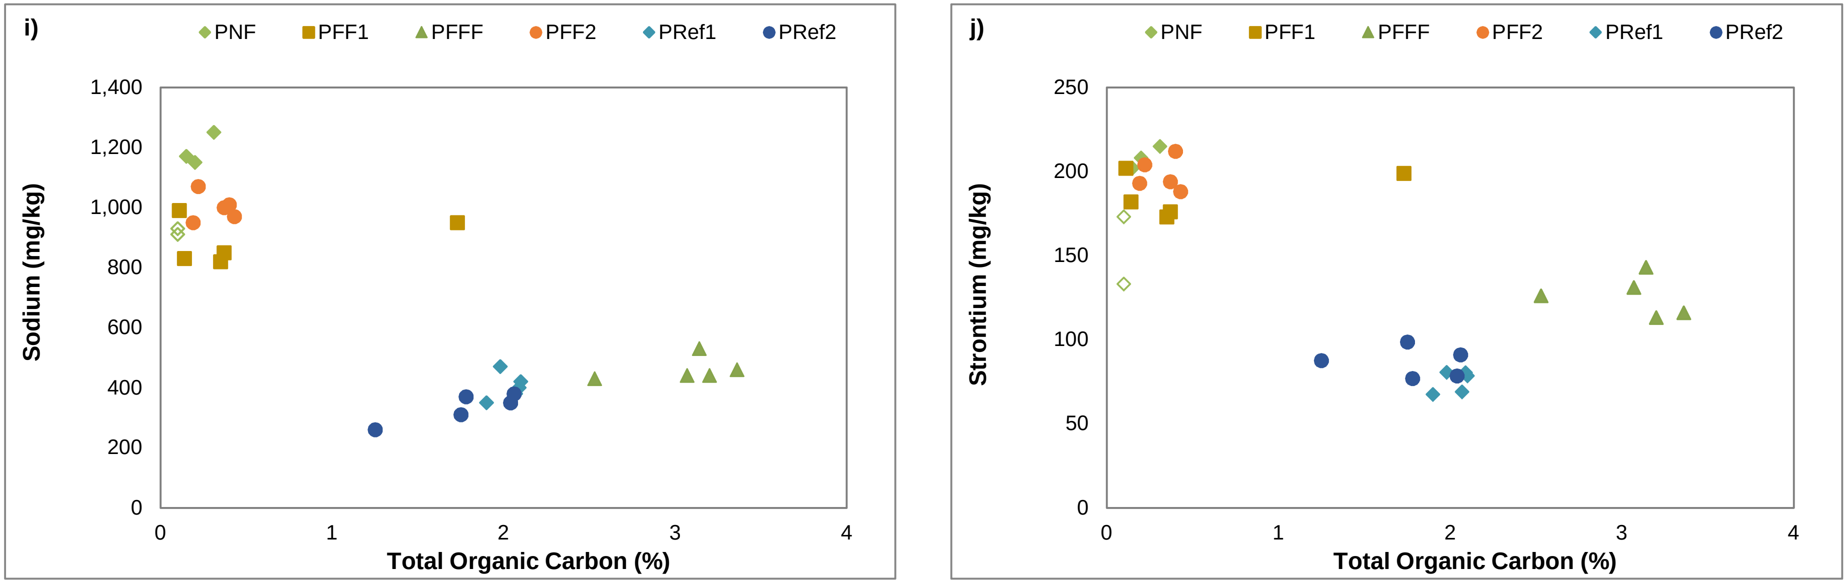

Figure E.30: Scatterplots of significant Spearman's correlation relationships ($p < 0.003$) between silt and clay (%) or total organic carbon (%), and parameters of interest or indicator parameters, Mount Polley Mine, 2014. Quesnel Lake profundal sampling areas. Hollow symbols indicate values < MDL.

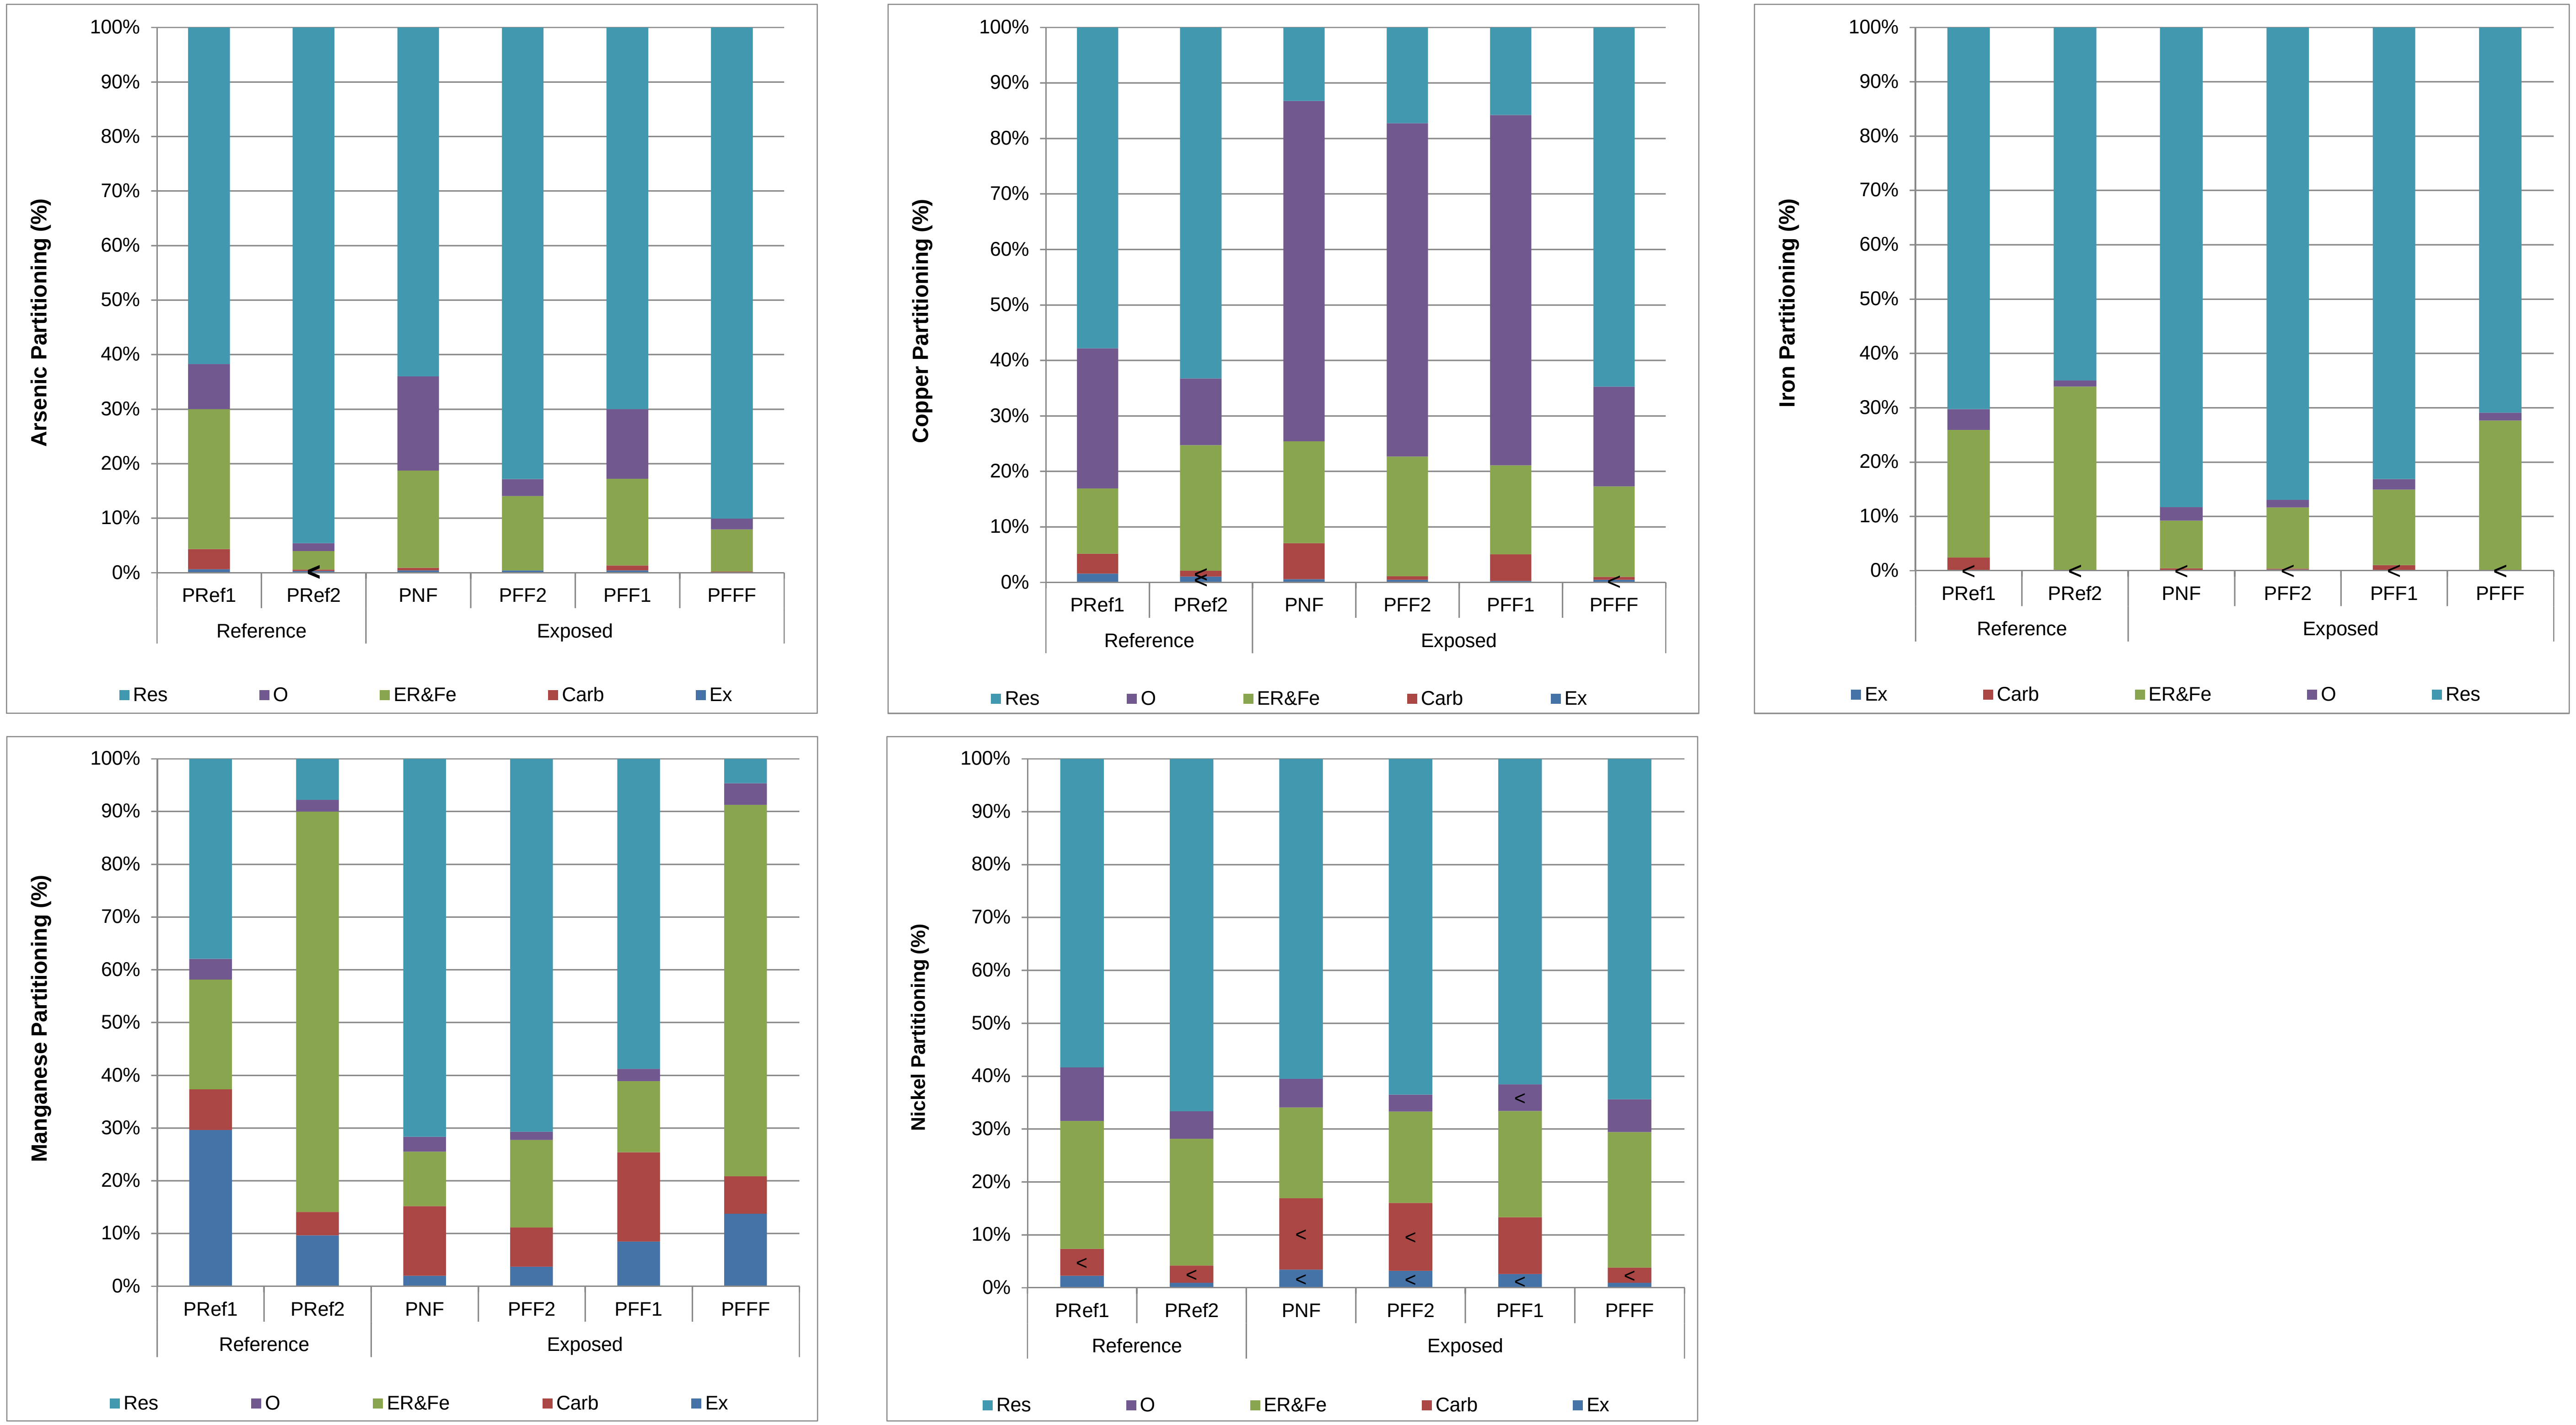

Figure E.31 (a): Partitioning of parameters of interest within selectively extracted fractions of sediment from the profundal sampling areas of Quesnel Lake, Mount Polley Mine, 2014. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic Bound Metals (O), and Residual Metals (Res).

Values < MDL are indicated with a < symbol. Mean values are plotted for areas with replicate samples (PRef1, PNF, PFF1), single values are plotted for composite samples (PRef2, PFF2, PFFF).

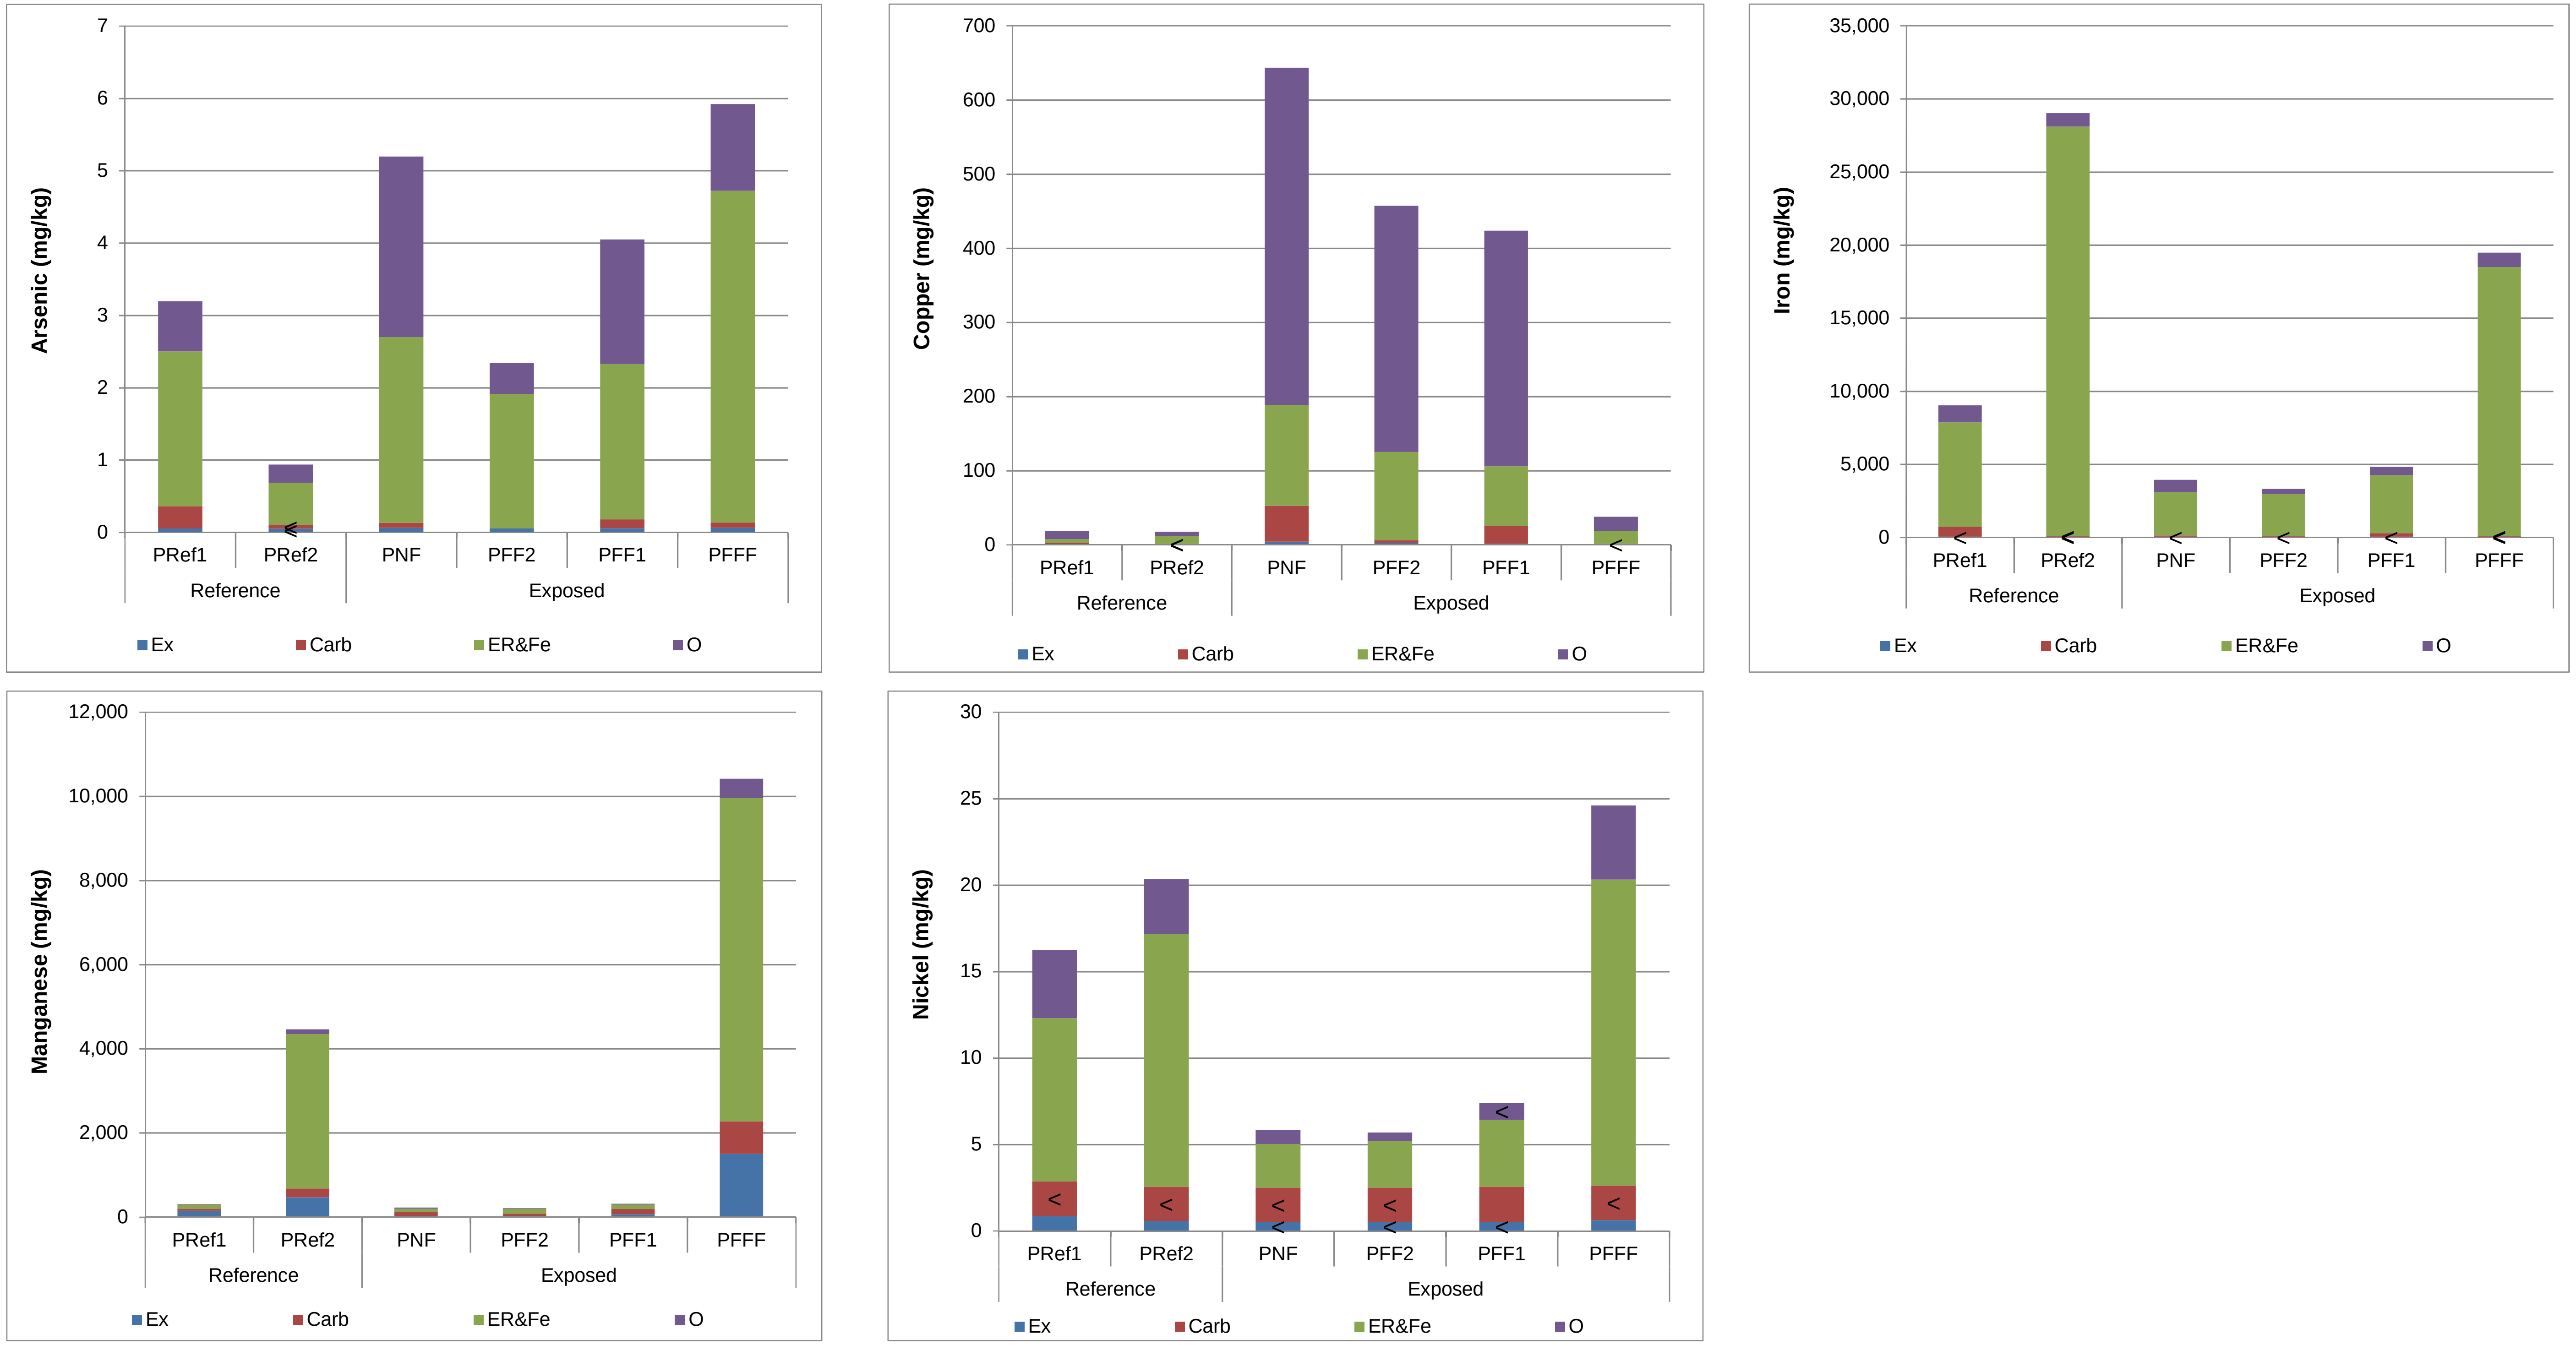

Figure E.31 (b): Mean concentrations of selectively extracted parameters of interest in sediment from the profundal sampling areas of Quesnel Lake, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) and Organic Bound Metals (O) fractions are shown (Residual metals are excluded).

Values < MDL are indicated with a < symbol. Mean values are plotted for areas with replicate samples (PRef1, PNF, PFF1), single values are plotted for composite samples (PRef2, PFF2, PFFF).

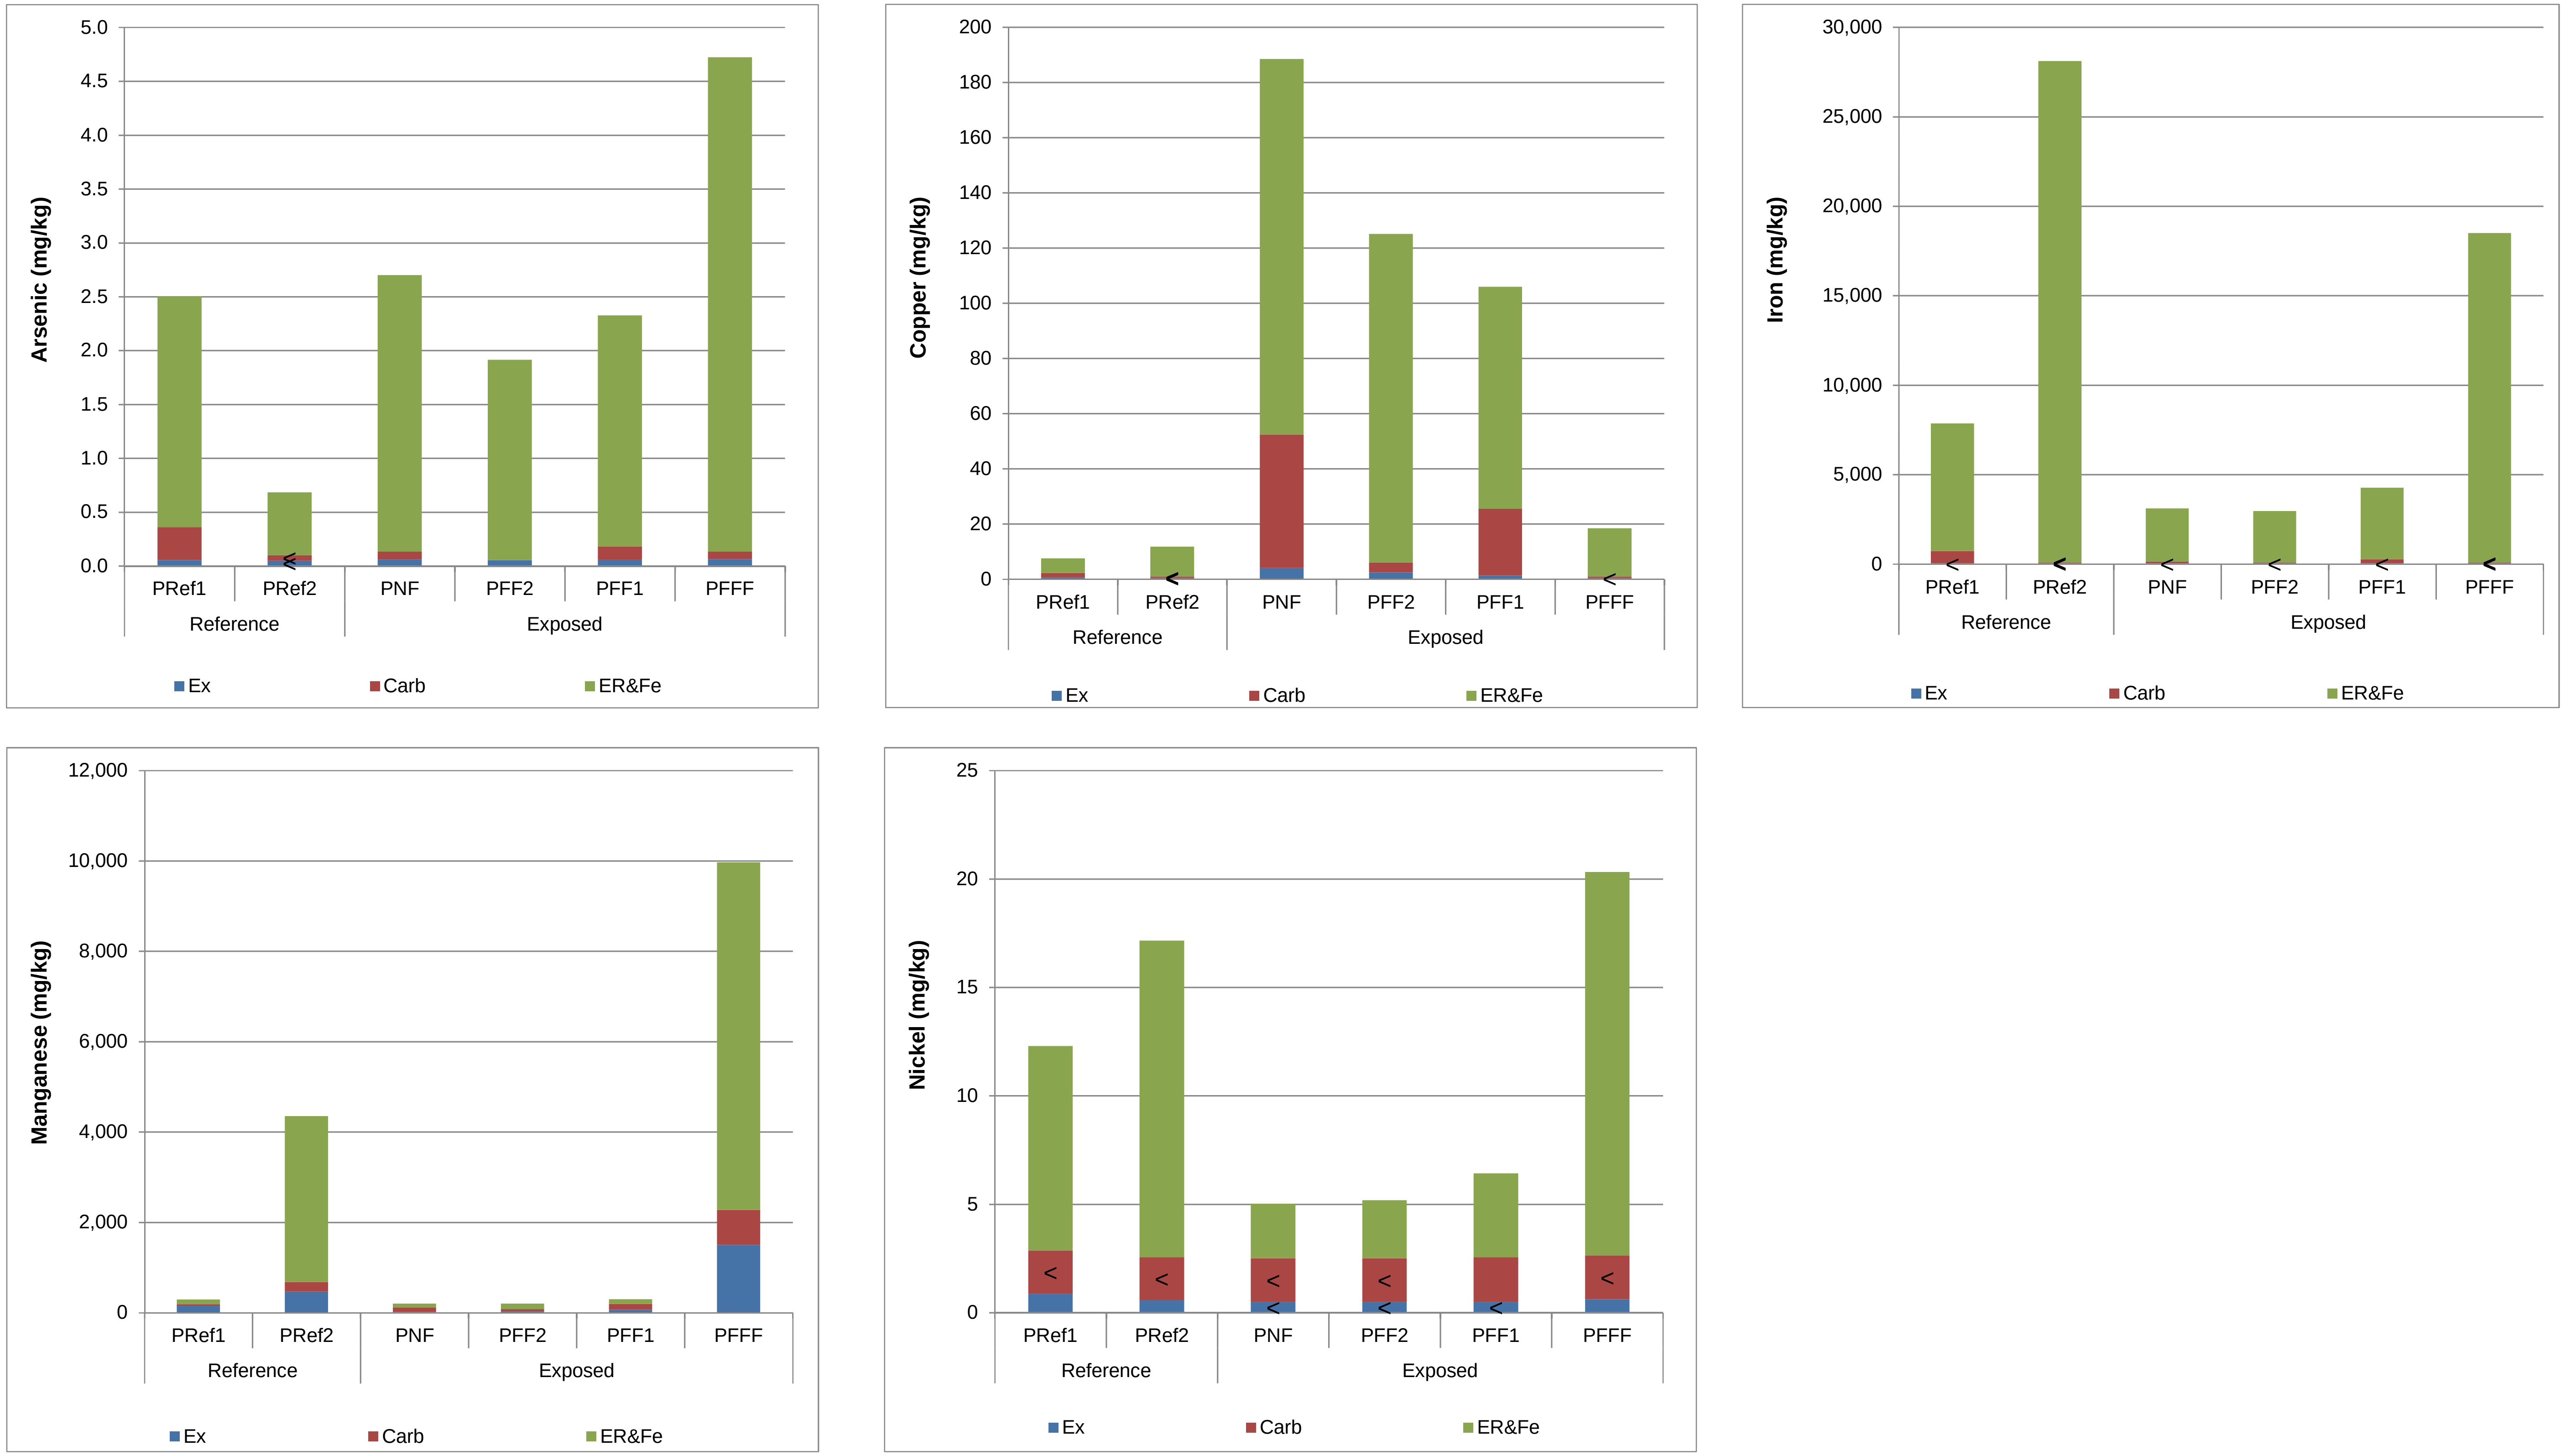

Figure E.31 (c): Mean concentrations of selectively extracted parameters of interest in sediment from the profundal sampling areas of Quesnel Lake, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) fractions are shown (Organic Bound and Residual metals are excluded).

Values < MDL are indicated with a < symbol. Mean values are plotted for areas with replicate samples (PRef1, PNF, PFF1), single values are plotted for composite samples (PRef2, PFF2, PFFF).

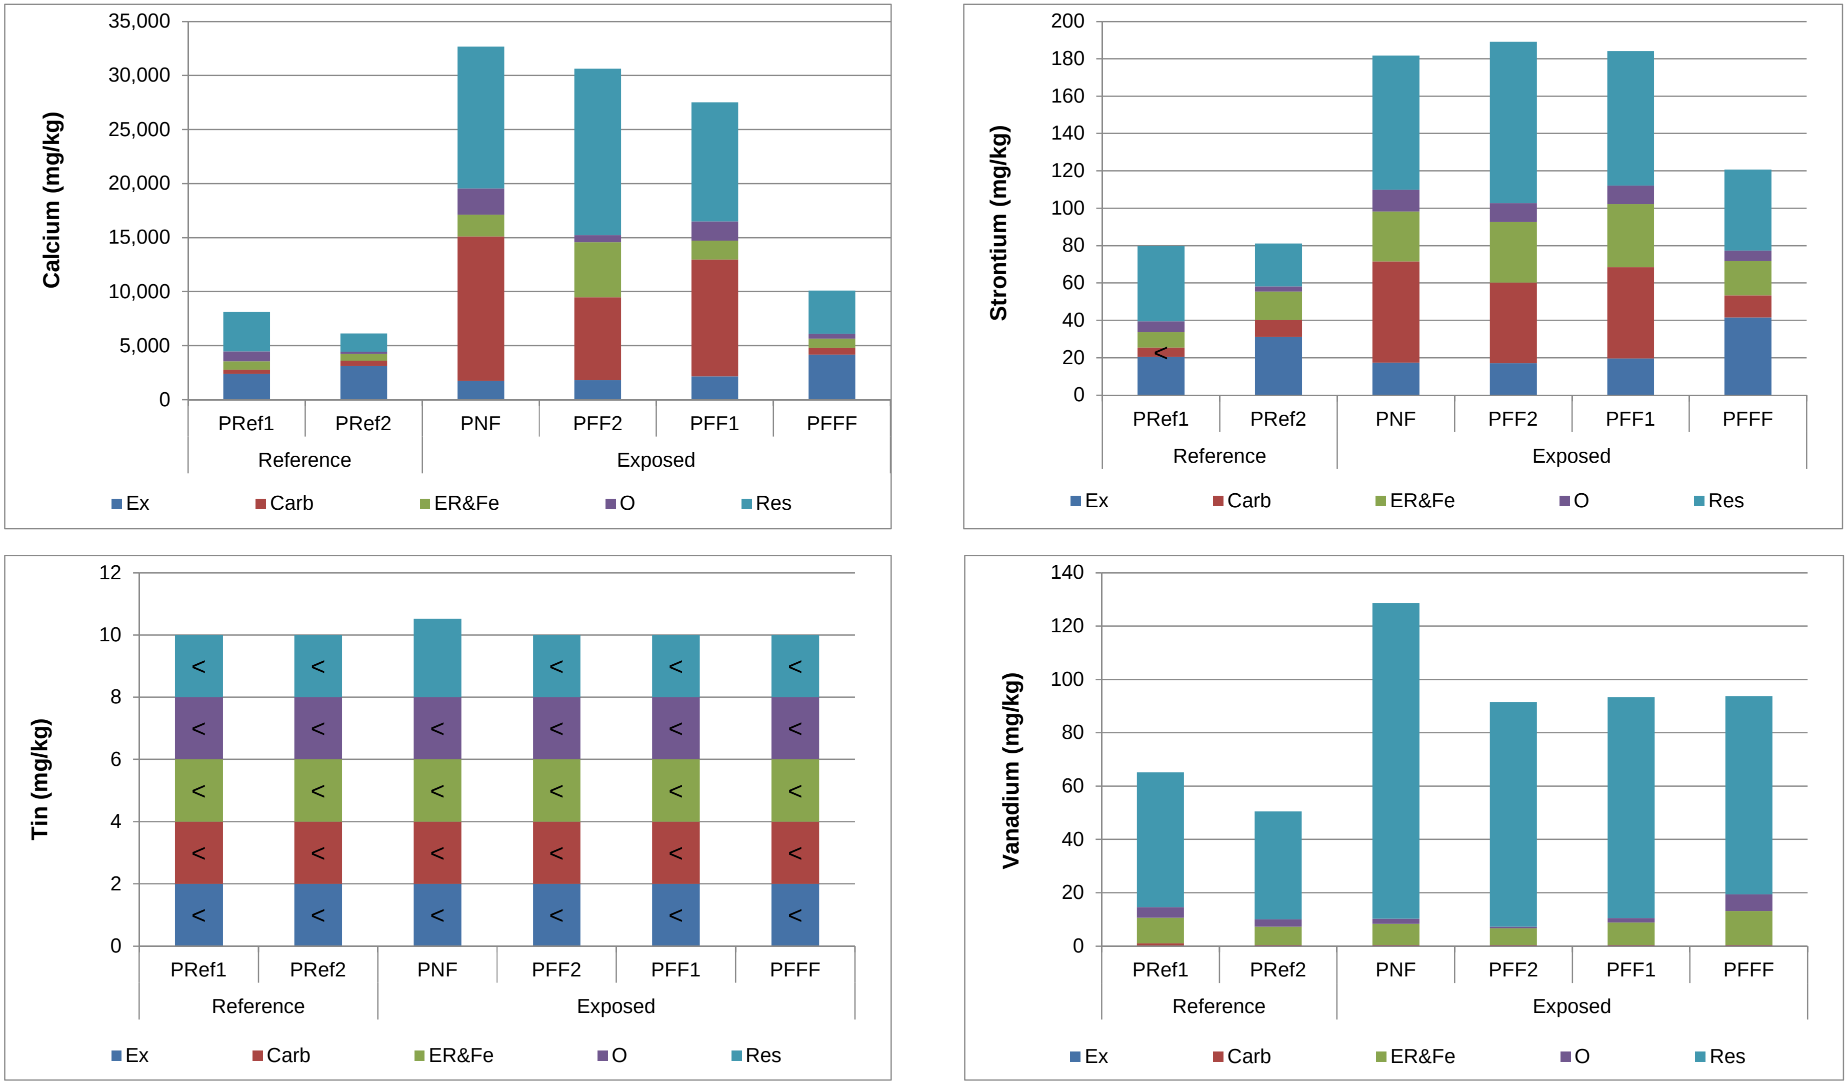

Figure E.32 (a): Mean concentrations of selectively extracted indicator parameters in sediment from the profundal sampling areas of Quesnel Lake, Mount Polley Mine, 2014. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic Bound Metals (O), and Residual Metals (Res).

Values < MDL are indicated with a < symbol. Mean values are plotted for areas with replicate samples (PRef1, PNF, PFF1), single values are plotted for composite samples (PRef2, PFF2, PFFF). Sodium data were available only for the Exchangeable & Adsorbed Metals fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result.

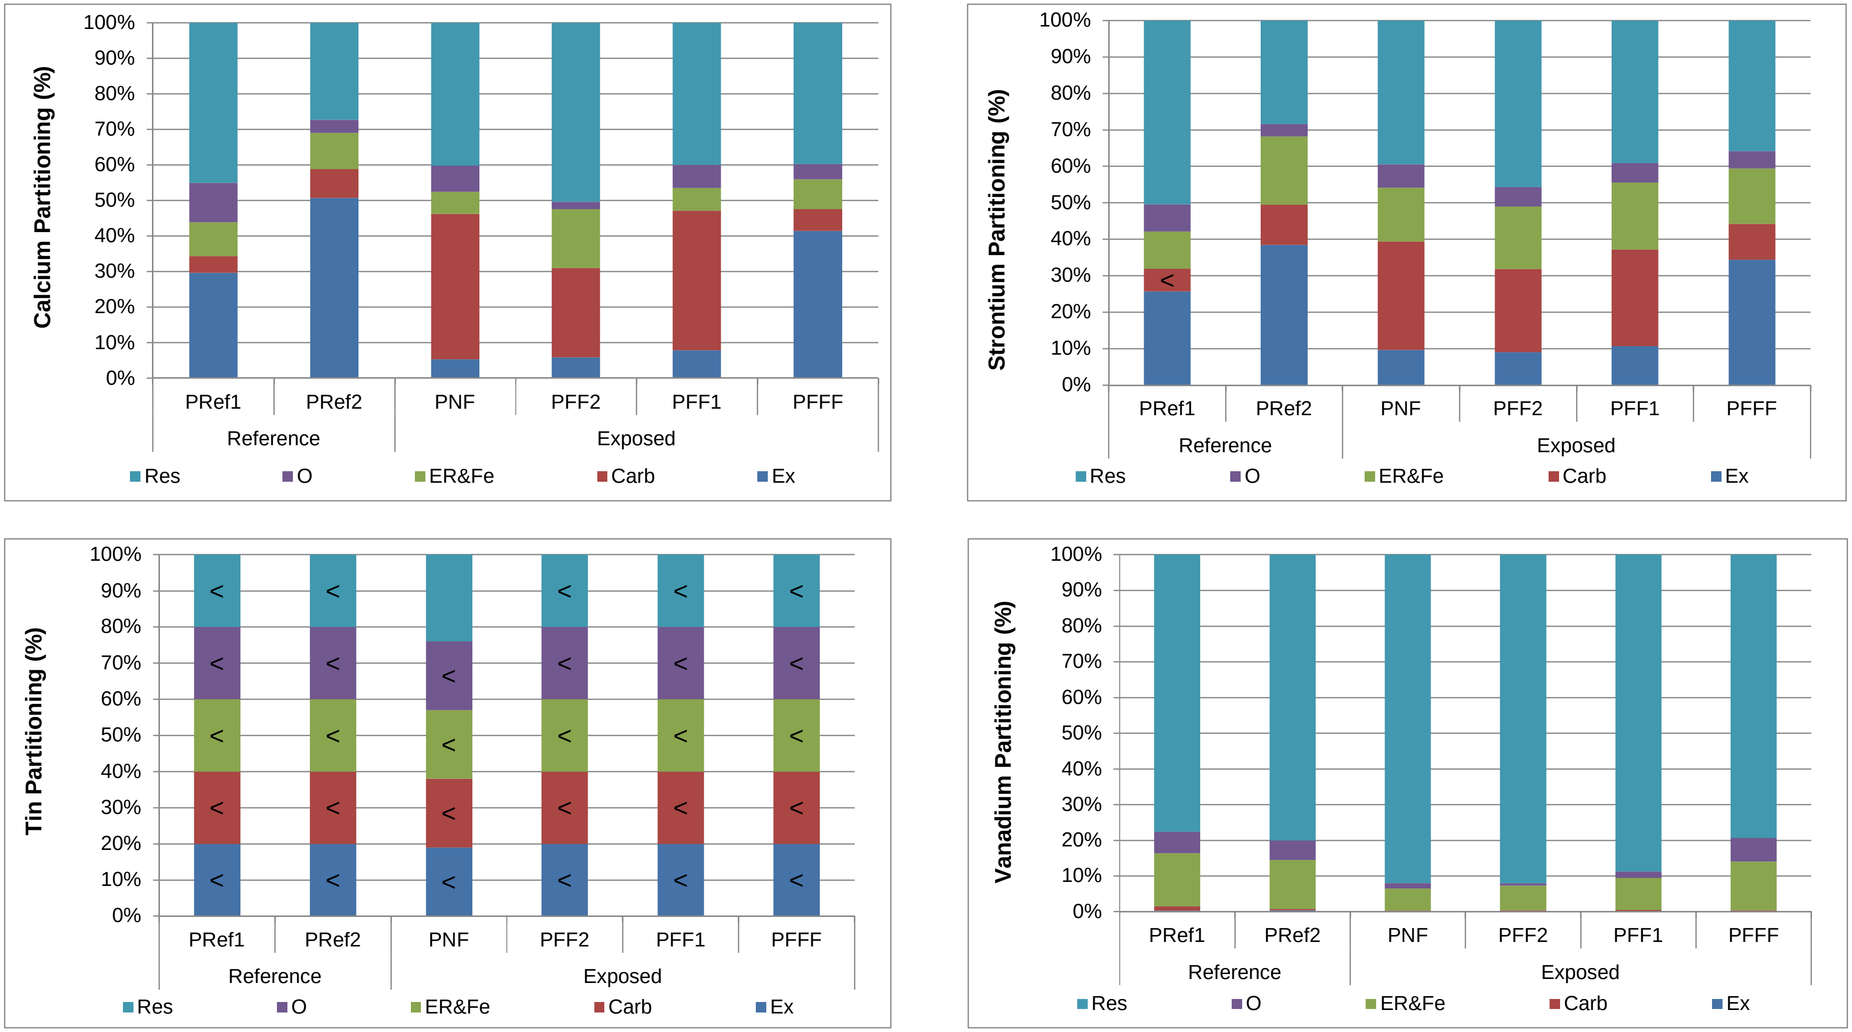

Figure E.32 (b): Partitioning of indicator parameters within selectively extracted fractions of sediment from the profundal sampling areas of Quesnel Lake, Mount Polley Mine, 2014. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic Bound Metals (O), and Residual Metals (Res).

Values < MDL are indicated with a < symbol. Mean values are plotted for areas with replicate samples (PRef1, PNF, PFF1), single values are plotted for composite samples (PRef2, PFF2, PFFF). Sodium data were available only for the Exchangeable & Adsorbed Metals fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result.

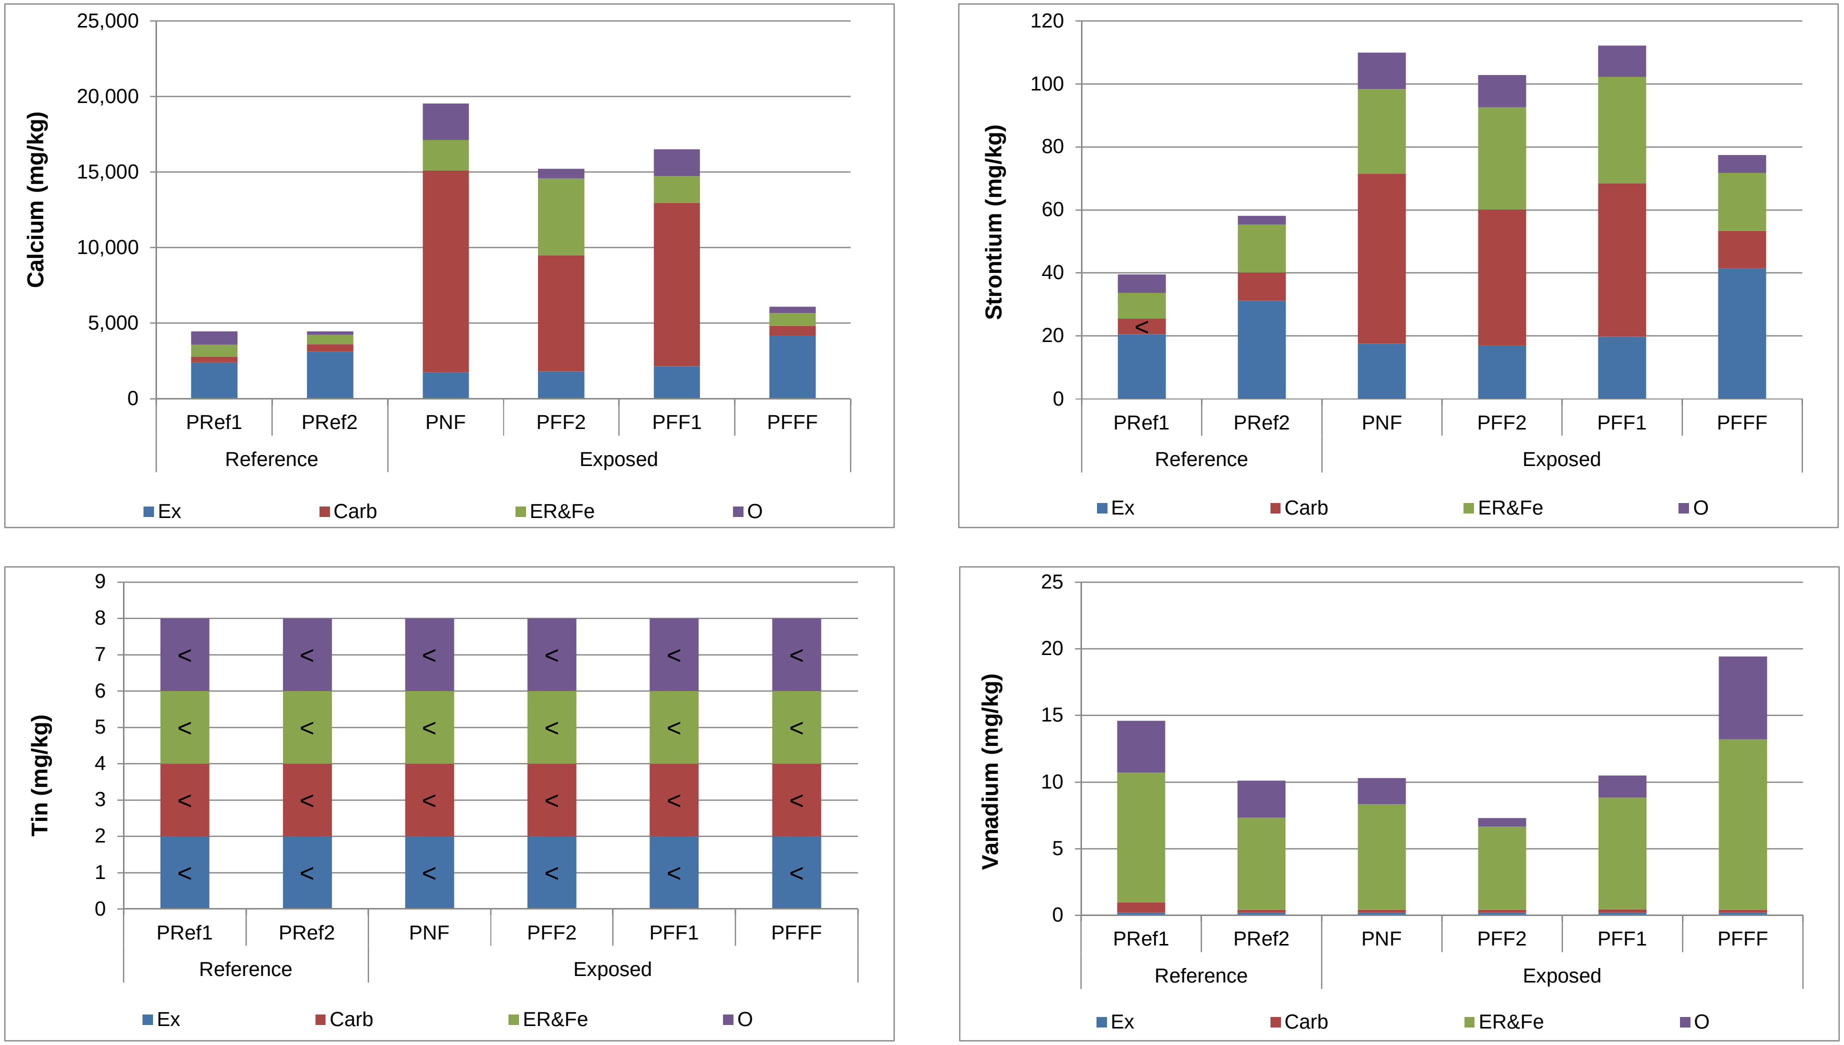

Figure E.32 (c): Mean concentrations of selectively extracted indicator parameters in sediment from the profundal sampling areas of Quesnel Lake, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) and Organic Bound Metals (O) fractions are shown (Residual metals are excluded).

Values < MDL are indicated with a < symbol. Mean values are plotted for areas with replicate samples (PRef1, PNF, PFF1), single values are plotted for composite samples (PRef2, PFF2, PFFF). Sodium data were available only for the Exchangeable & Adsorbed Metals fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result.

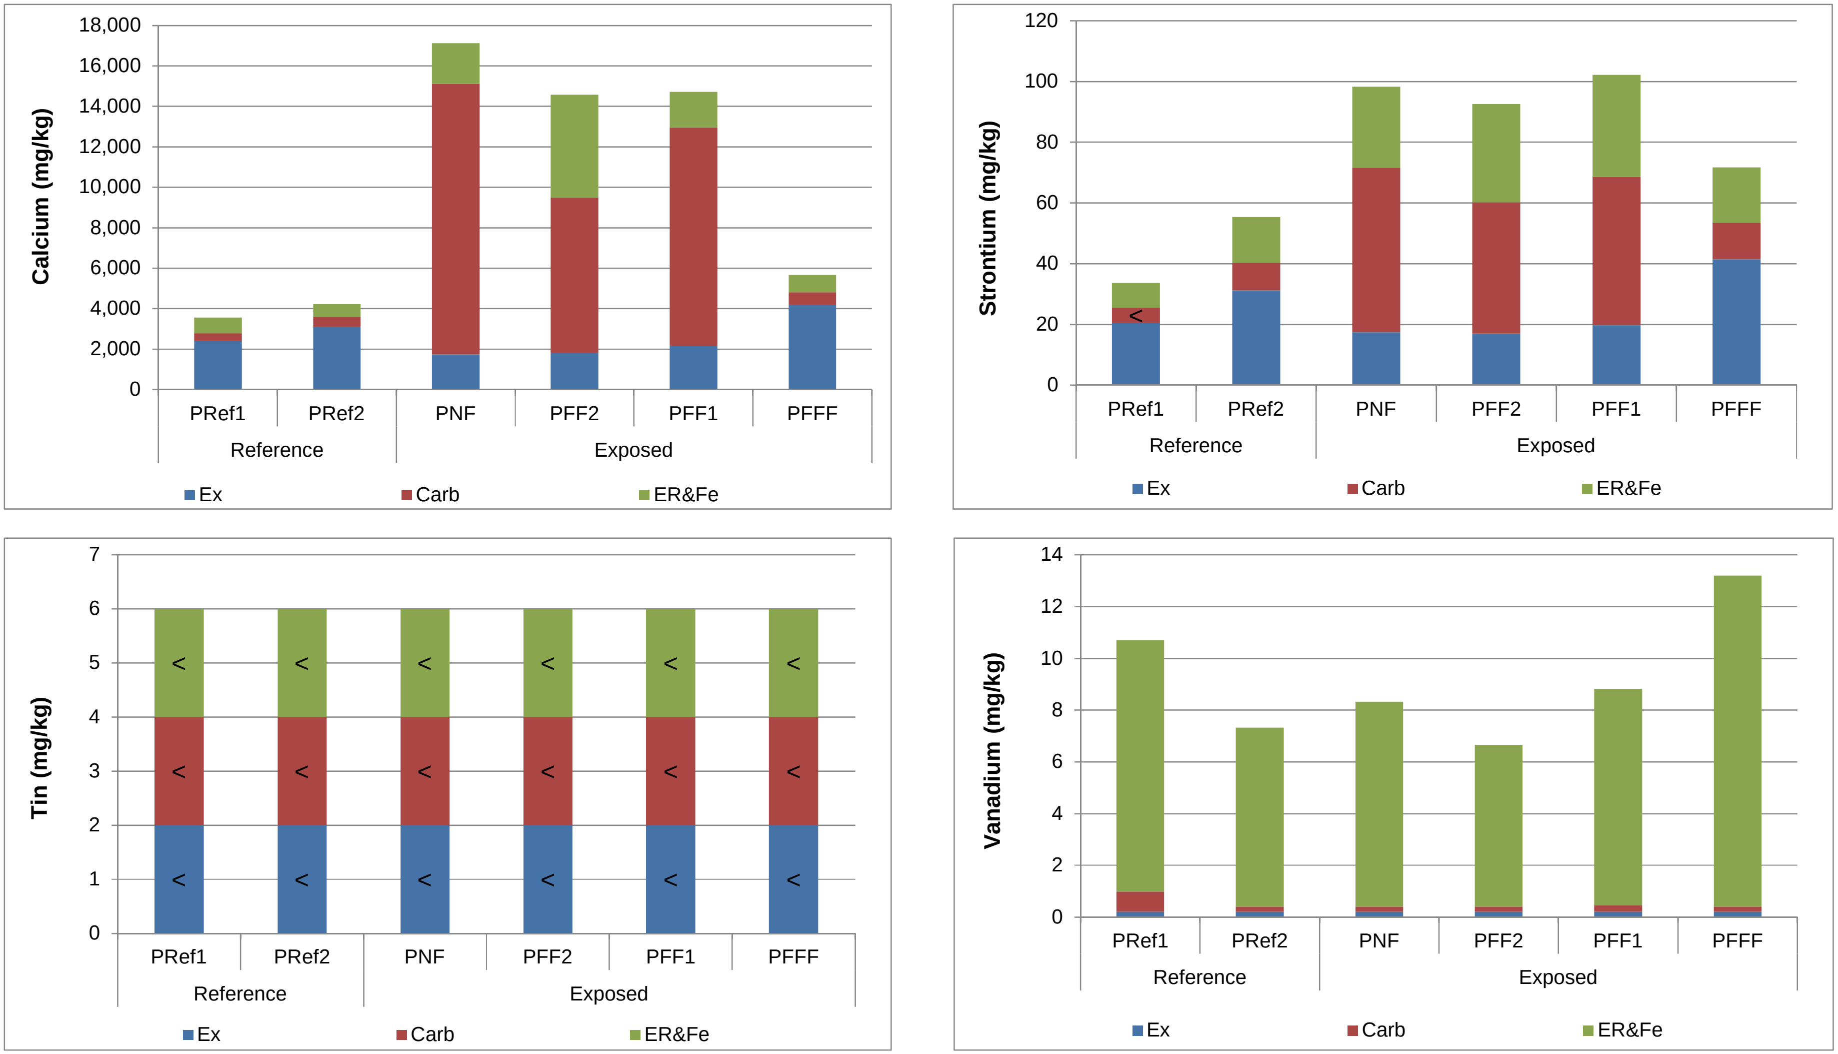

Figure E.32 (d): Mean concentrations of selectively extracted indicator parameters in sediment from the profundal sampling areas of Quesnel Lake, Mount Polley Mine, 2014. Only metals within the Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe) fractions are shown (Organic Bound and Residual metals are excluded).

Values < MDL are indicated with a < symbol. Mean values are plotted for areas with replicate samples (PRef1, PNF, PFF1), single values are plotted for composite samples (PRef2, PFF2, PFFF). Sodium data were available only for the Exchangeable & Adsorbed Metals fraction due to the use of sodium in the second extraction step; sodium was not plotted as a result.

Figure E.33: Sediment cores collected from Quesnel Lake near field (QUL-PW-1) for profiles of pore-water (left core) and sediment chemistry (right core).

Highlighted values indicate significance at the $p < 0.05$ level.

Figure F.1: Toxicity tests of Polley and Bootjack Mid-depth Sediment on *Hyalella azteca*, Mount Polley Mine, 2014. Results for a) Survival (%), b) Normalized Survival (%), c) Dry Weight (mg), d) Normalized Dry Weight (%). Error bars represent standard deviation and differing colours indicate different laboratory batches. Letters represent significant differences (Y) or no differences (N) between samples and the Control (Black) and Reference (Orange) ($p<0.05$).

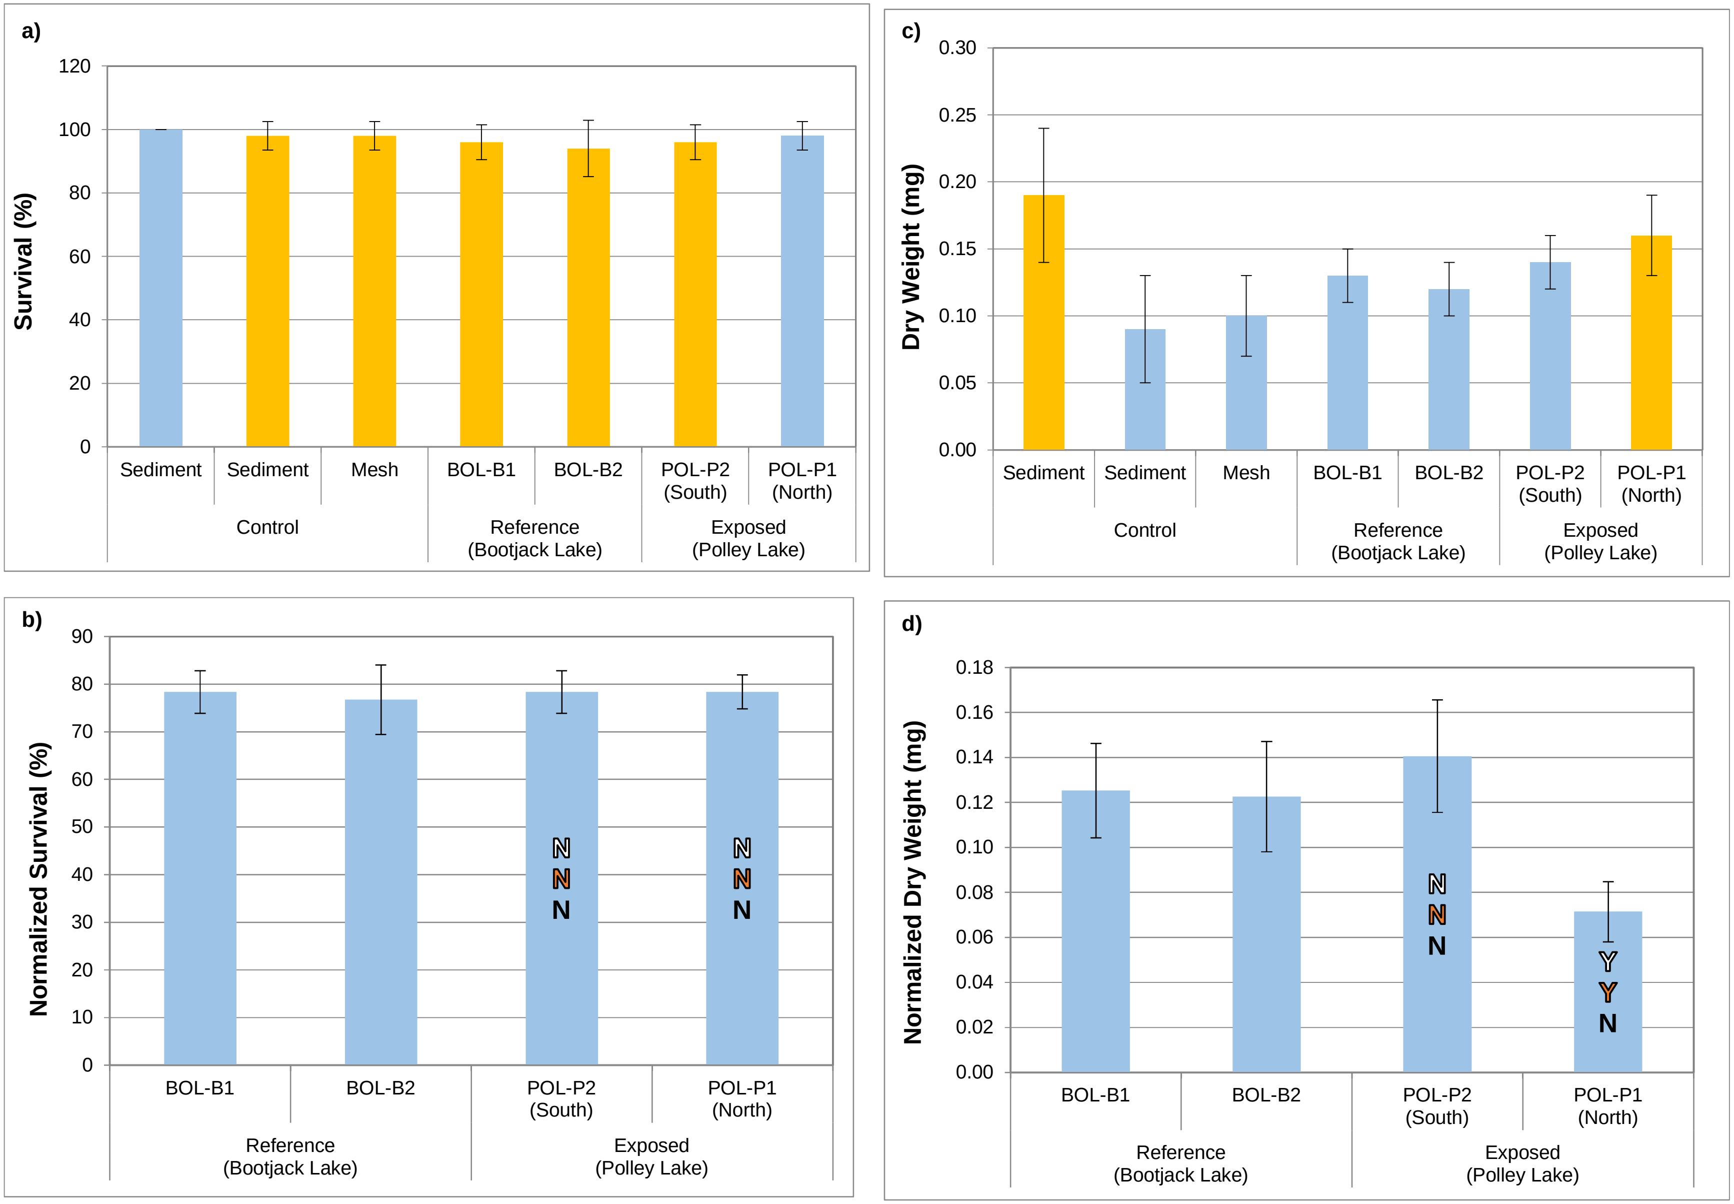

Figure F.2: Toxicity tests of Polley and Bootjack Deep Sediment on *Hyalella azteca* , Mount Polley Mine, 2014. Results for a) Survival (%), b) Normalized Survival (%), c) Dry Weight (mg), d) Normalized Dry Weight (%). Error bars represent standard deviation and differing colours indicate different laboratory batches. Letters represent significant differences (Y) or no differences (N) between samples and the Control (Black), Reference 1 (Orange) and Reference 2 (White) ($p < 0.05$).

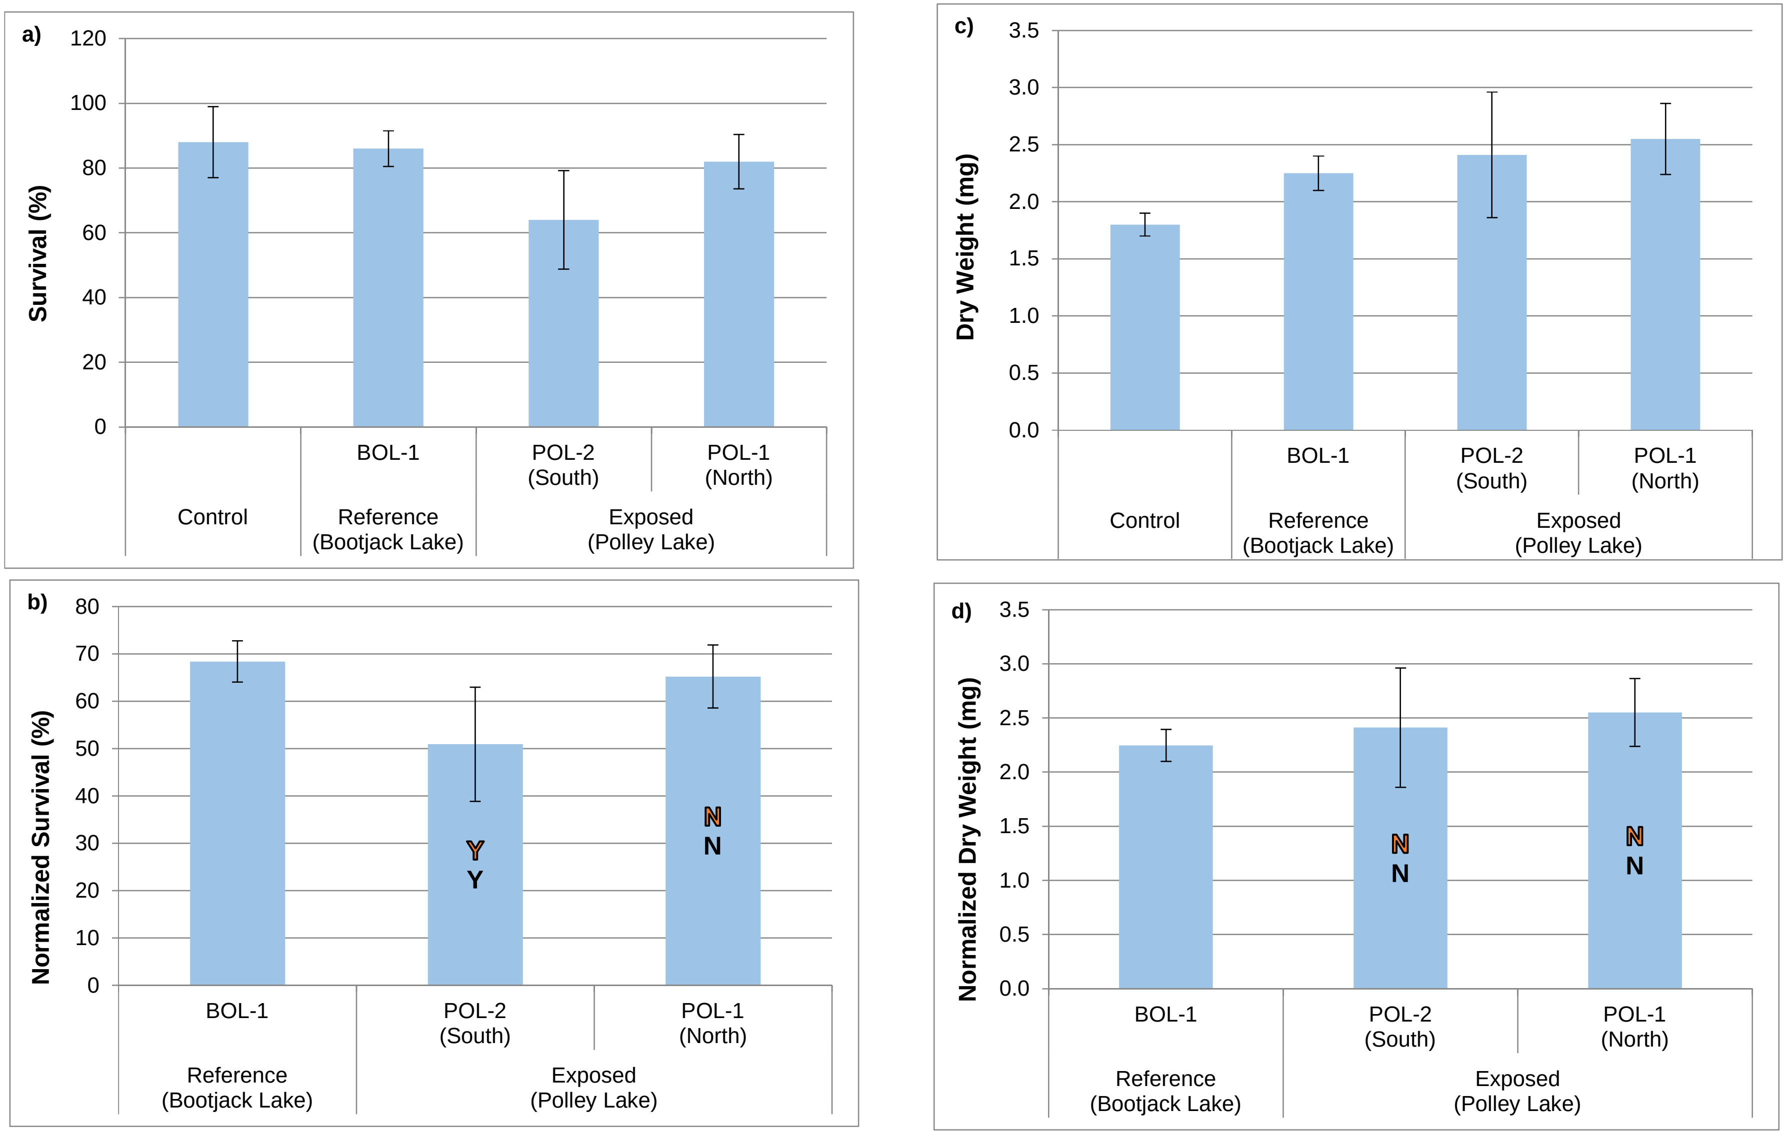

Figure F.3: Toxicity tests of Polley and Bootjack Mid-depth Sediment on *Chironomus dilutus* , Mount Polley Mine, 2014. Results for a) Survival (%), b) Normalized Survival (%), c) Dry Weight (mg), d) Normalized Dry Weight (%). Error bars represent standard deviation and differing colours indicate different laboratory batches. Letters represent significant differences (Y) or no differences (N) between samples and the Control (Black) and Reference (Orange) ($p < 0.05$).

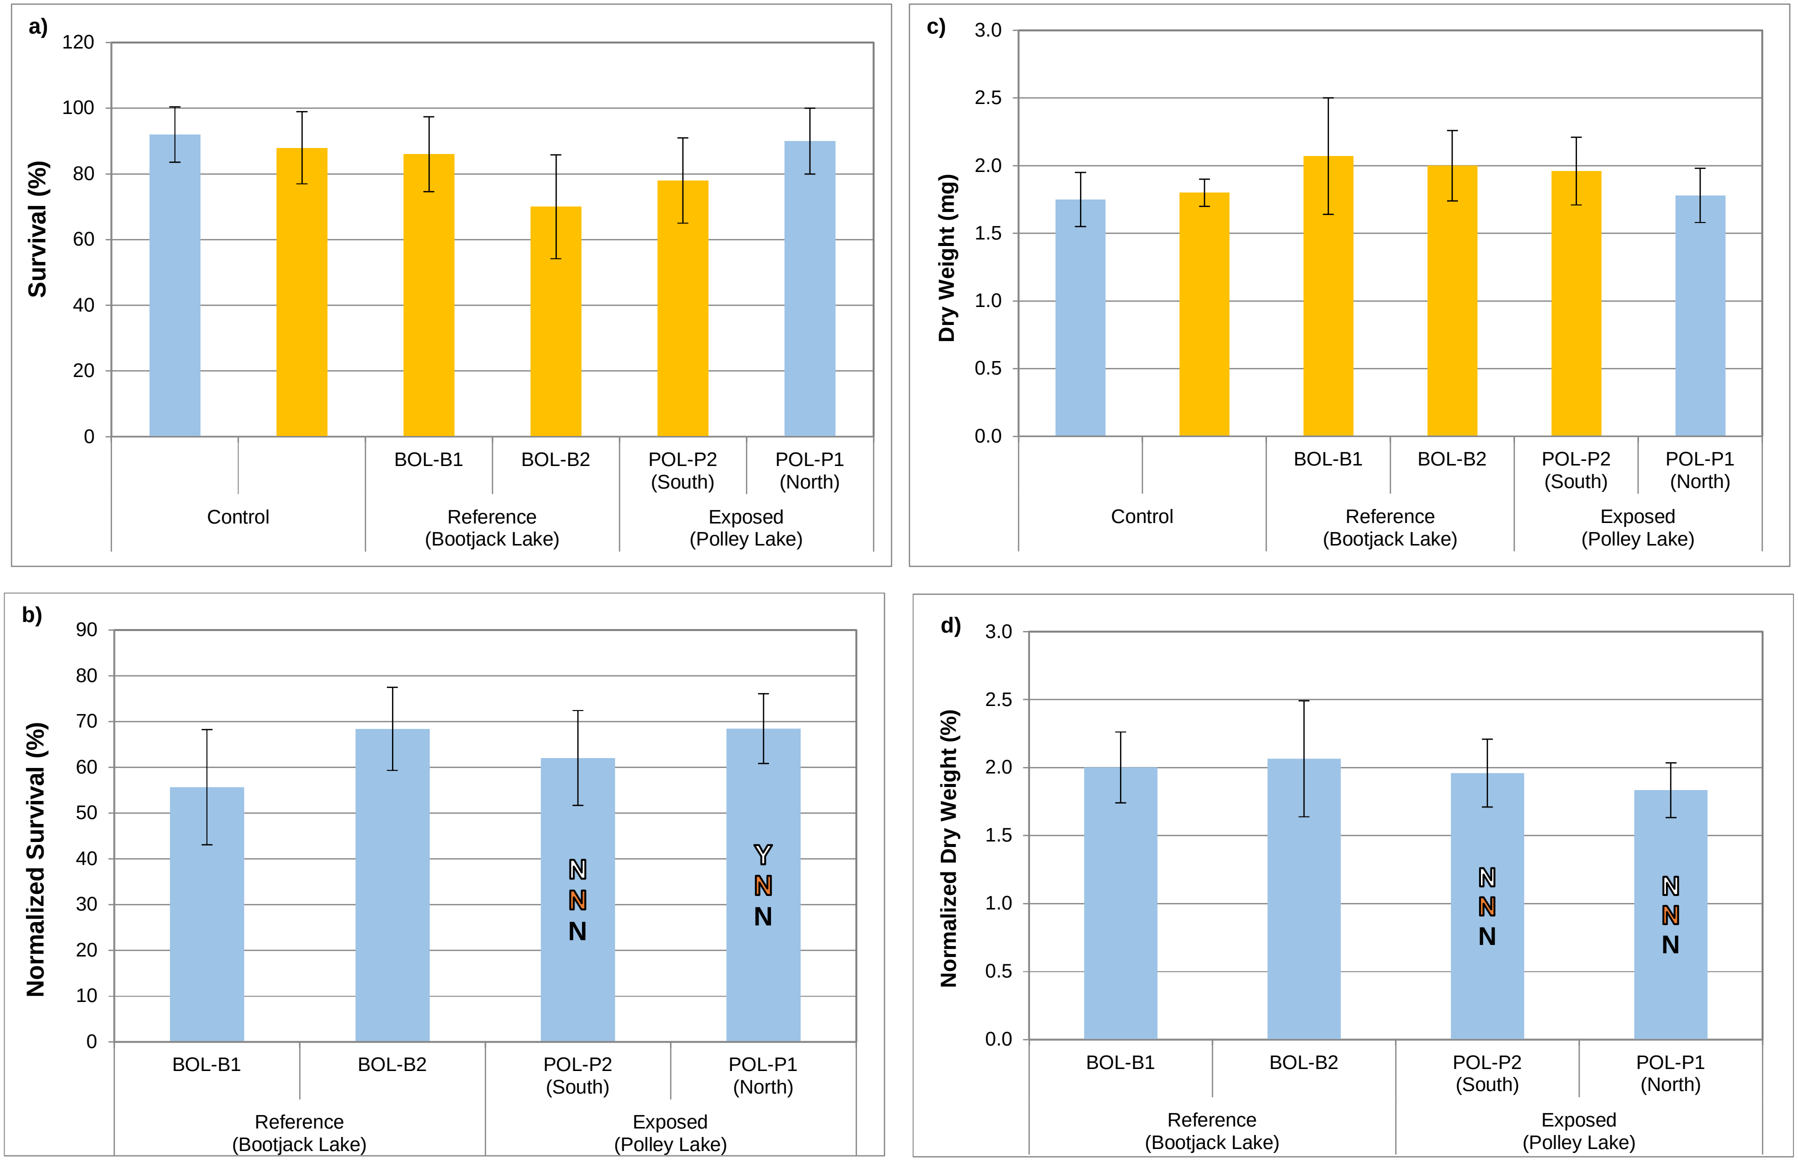

Figure F.4: Toxicity tests of Polley and Bootjack Deep Sediment on *Chironomus dilutus* , Mount Polley Mine, 2014. Results for a) Survival (%), b) Normalized Survival (%), c) Dry Weight (mg), d) Normalized Dry Weight (%). Error bars represent standard deviation and differing colours indicate different laboratory batches. Letters represent significant differences (Y) or no differences (N) between samples and the Control (Black), Reference 1 (Orange) and Reference 2 (White) ($p < 0.05$).

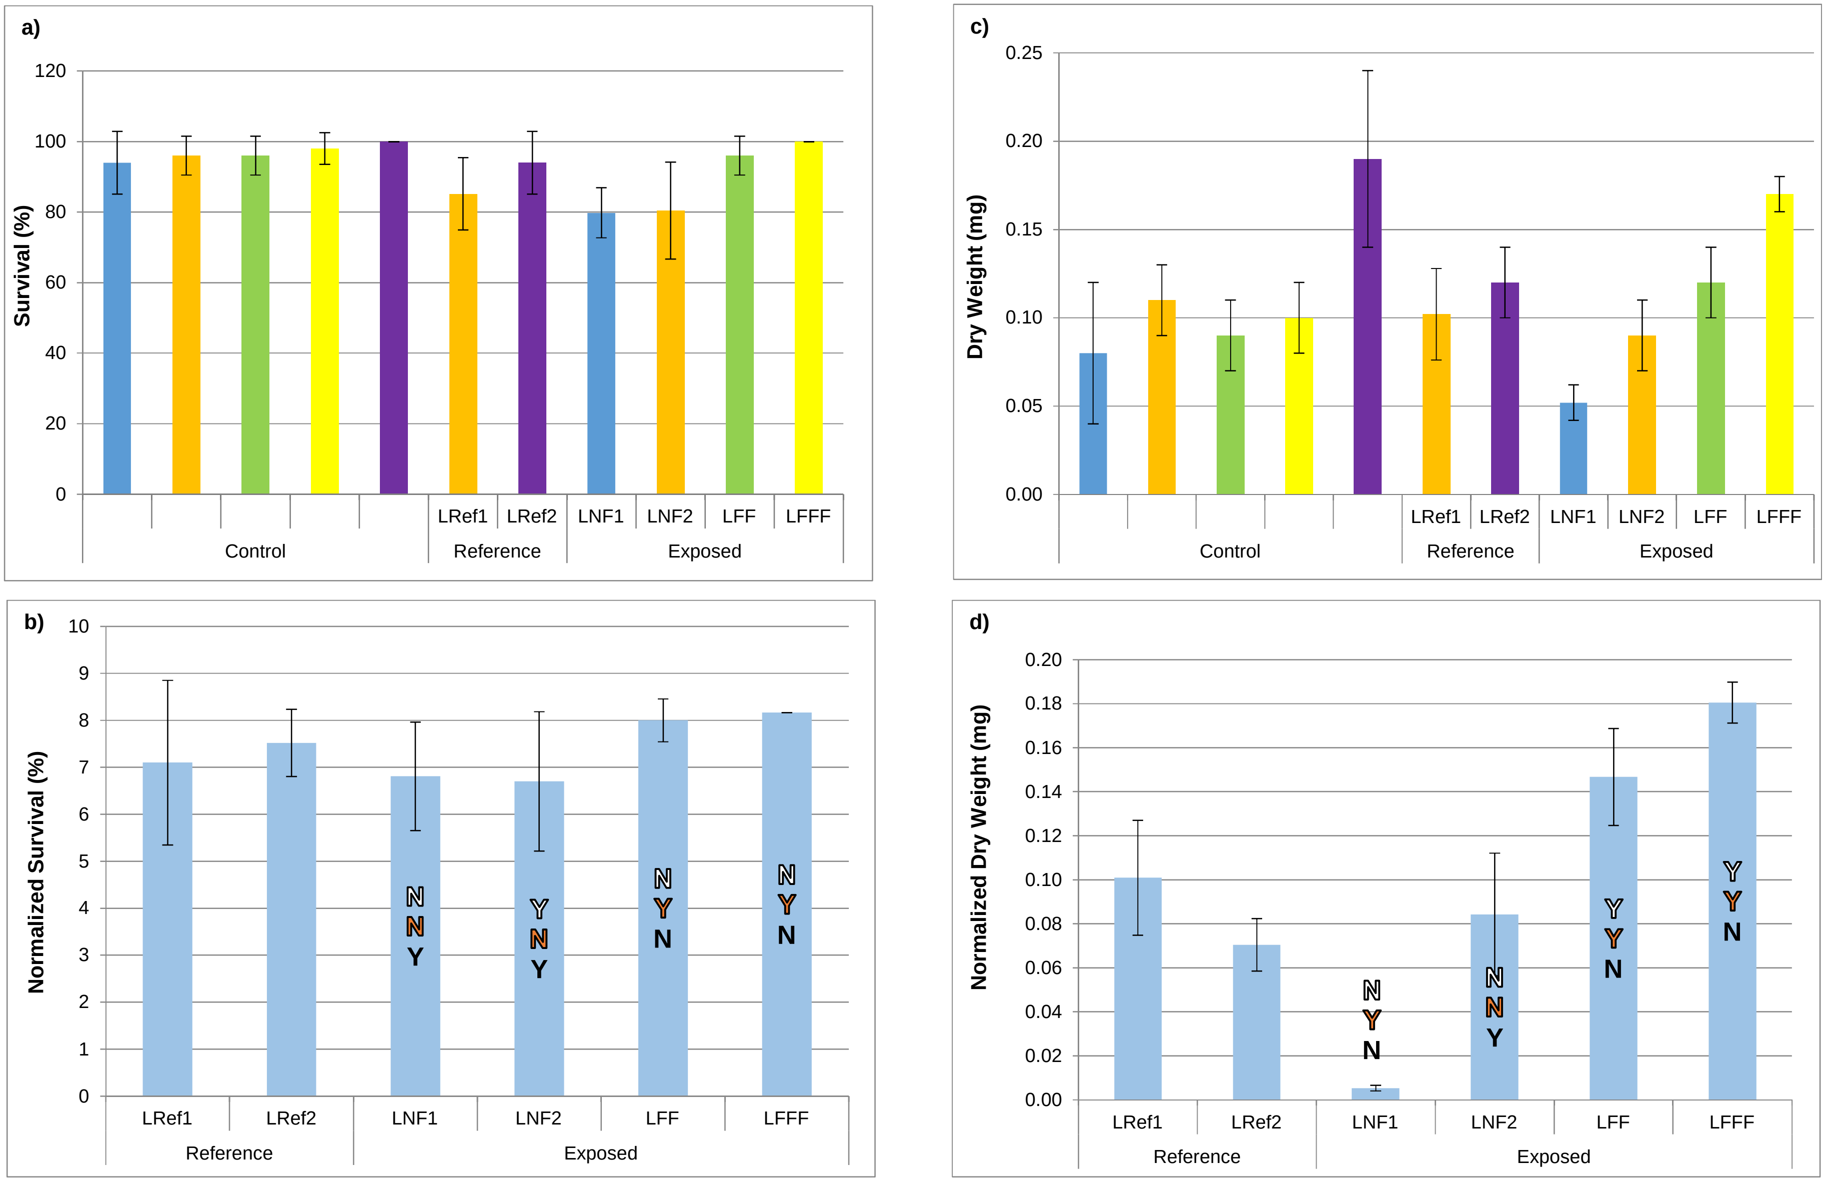

Figure F.5: Toxicity tests of Quesnel Lake littoral sediment on *Hyalella azteca*, Mount Polley Mine, 2014. Results for a) Survival (%), b) Normalized Survival (%), c) Dry Weight (mg), d) Nornalized Dry Weight (mg). Error bars represent standard deviation and differing colours indicate different laboratory batches. Letters represent significant differences (Y) or no differences and the Control (Black), Reference 1 (Orange) and Reference 2 (White) ($p < 0.05$).

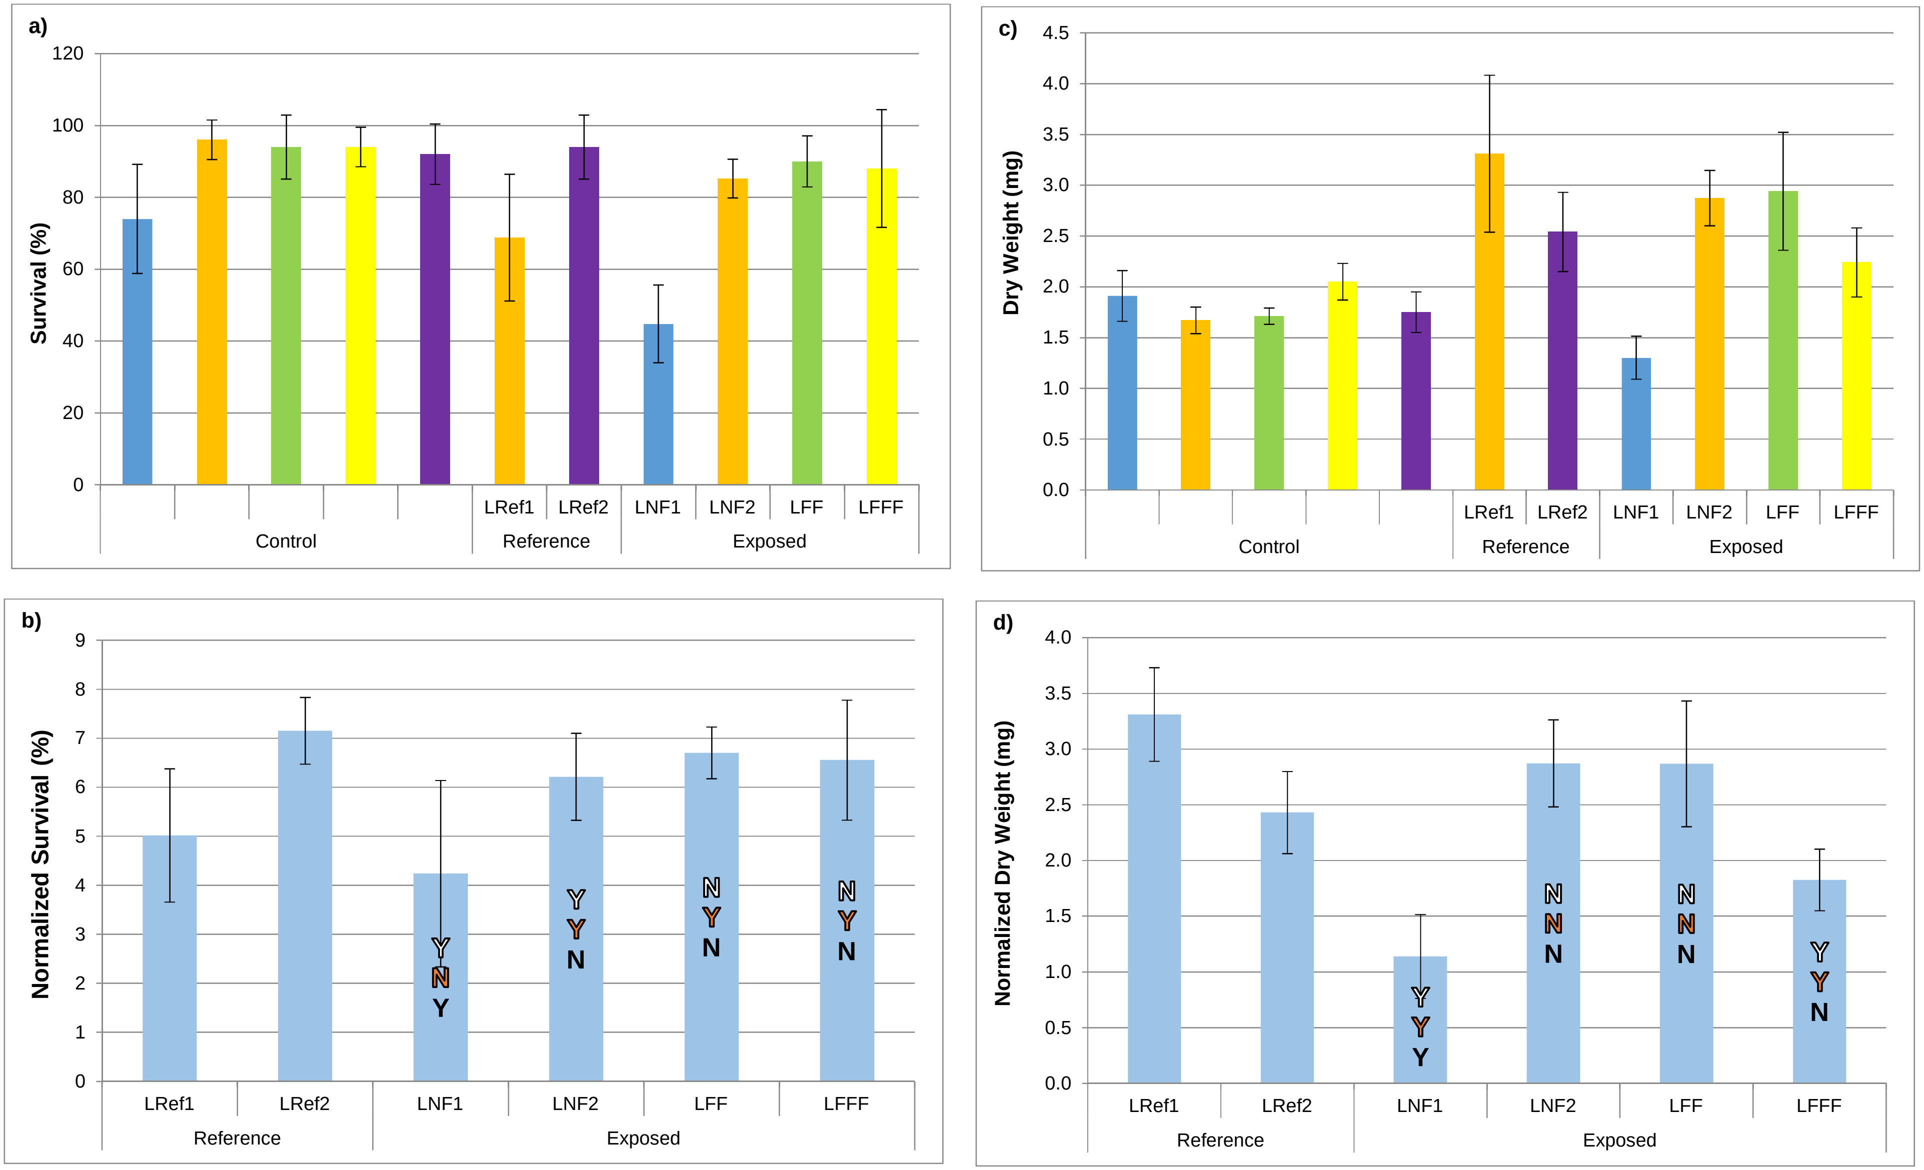

Figure F.6: Toxicity tests of Quesnel Lake littoral sediment on *Chironomus dilutus*, Mount Polley Mine, 2014. Results for a) Survival (%), b) Normalized Survival (%), c) Dry Weight (mg), d) Normalized Dry Weight (mg). Error bars represent standard deviation and differing colours indicate different laboratory batches. Letters represent significant differences (Y) or no differences (N) between samples and the Control (Black), Reference 1 (Orange) and Reference 2 (White) ($p < 0.05$).

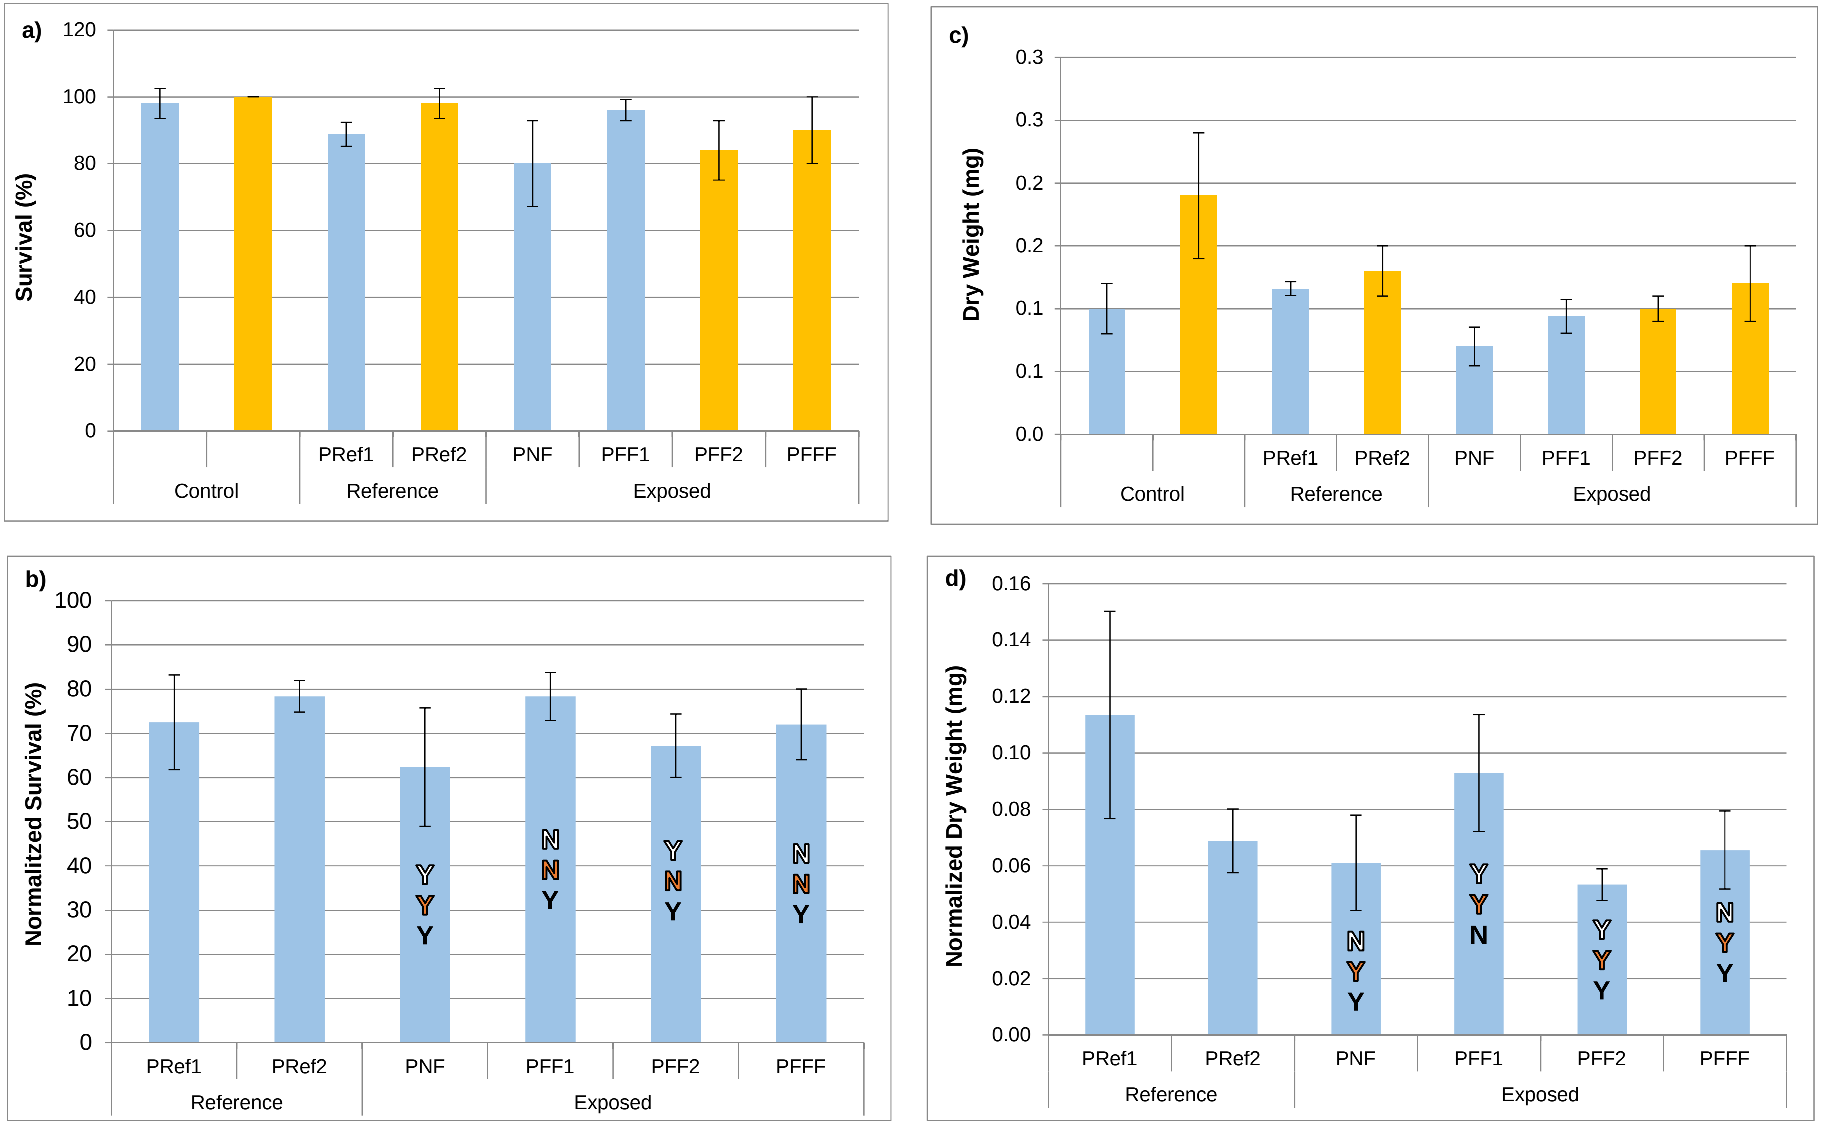

Figure F.7: Toxicity tests of Quesnel Lake profundal sediment on *Hyalella azteca* , Mount Polley Mine, 2014. Results for a) Survival (%), b) Normalized Survival (%), c) Dry Weight (mg), d) Normalized Dry Weight (mg). Error bars represent standard deviation and differing colours indicate different laboratory batches. Letters represent significant differences (Y) or no differences (N) between samples and the Control (Black), Reference 1 (Orange) and Reference 2 (White) ($p < 0.05$).

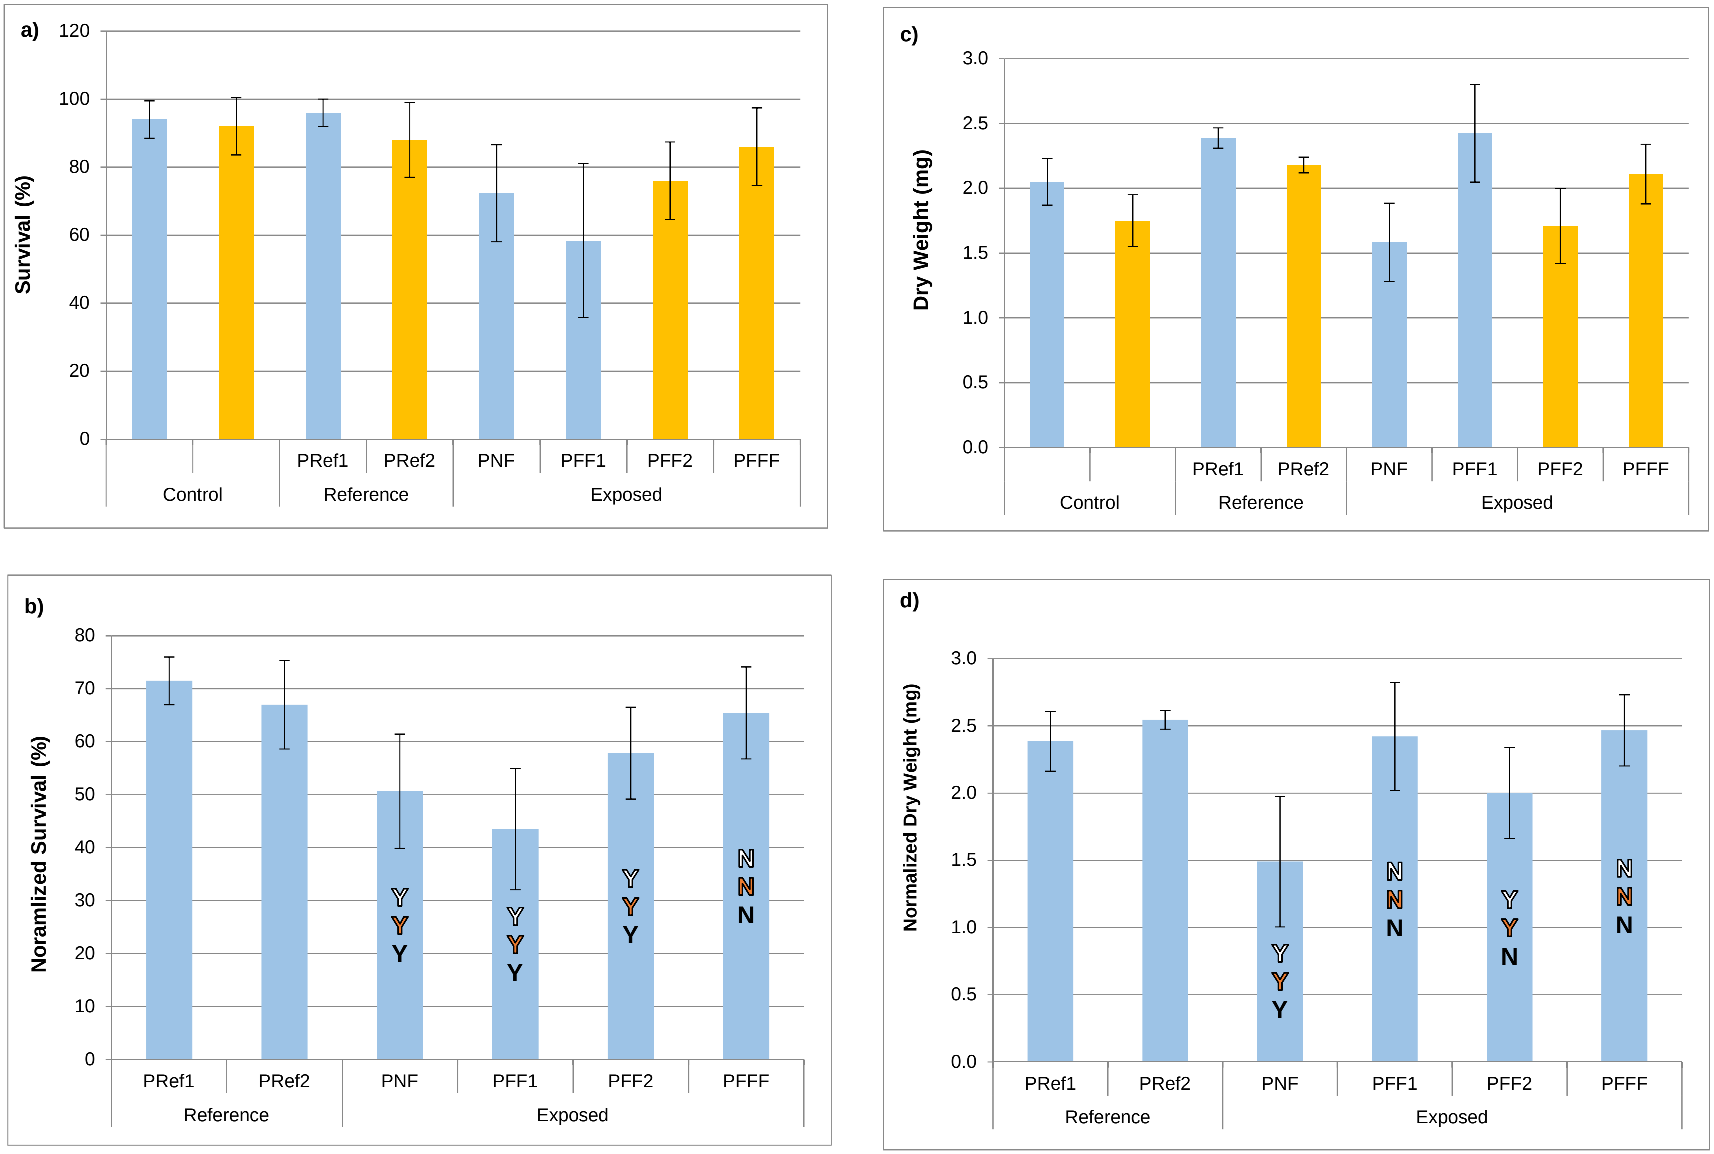

Figure F.8: Toxicity tests of Quesnel Lake profundal sediment on *Chironomus dilutus* , Mount Polley Mine, 2014. Results for a) Survival (%), b) Normalized Survival (%), c) Dry Weight (mg), d) Normalized Dry Weight (mg). Error bars represent standard deviation and differing colours indicate different laboratory batches. Letters represent significant differences (Y) or no differences (N) between samples and the Control (Black), Reference 1 (Orange) and Reference 2 (White) ($p < 0.05$).

[a] Bonferroni post-hoc Test, or Tamhane's T2 Test where variances were found to be heterogenous by Levene's Test

[b] p-value obtained from post-hoc analysis of 1-way ANOVA among all areas (post-hoc analyses protected for multiple comparisons)

[c] Magnitude calculated by comparing the difference between the reference area (I) and exposure area (J) means to the reference area (I) standard deviation (SD) [(exposure mean - reference mean) / standard deviation of the reference mean]

[d] Minimum effect size detectable calculated based on variance as square root of MSE from ANOVA and alpha = beta = 0.10.
Minimum effect size reported as the minimum number of standard deviations detectable based on reference area standard deviation.

Table G.3: Descriptive statistics of benthic metrics values for mid-depth benthic sample stations in Bootjack and Polley Lakes, Mount Polley Mine, 2014.

[a] Bonferroni post-hoc Test, or Tamhane's T2 Test where variances were found to be heterogenous by Levene's Test
[b] p-value obtained from post-hoc analysis of 1-way ANOVA among all areas (post-hoc analyses protected for multiple comparisons)
[c] Magnitude calculated by comparing the difference between the reference area (I) and exposure area (J) means to the reference area (I) standard deviation (SD) [(exposure mean - reference mean) / standard deviation of the reference mean]
[d] Minimum effect size detectable calculated based on variance as square root of MSE from ANOVA and alpha = beta = 0.10. Minimum effect size reported as the minimum number of standard deviations detectable based on reference area standard deviation.

Table G.16: Descriptive statistics for benthic metrics from Quesnel Lake littoral areas, Mount Polley Mine, 2014.

Table G.18: Benthic taxon scores from Correspondence Analysis of samples from Quesnel Lake littoral areas, Mount Polley Mine, 2014.

Taxon	CA-1 (19.0%)	CA-2 (16.3%)
Family: Baetidae: incl. Baetis, Callibaetis	0.022	-0.230
Caenis sp., incl. C. youngi	0.612	0.526
Ephemera simulans and Ephemeridae	0.440	0.658
Oxyethira sp.	0.483	0.420
Mystacides	0.392	-0.001
Oecetis	0.216	0.522
Family: Limnephilidae, incl. Chyranda centralis, Limnephilus, unident. Limnephilidae	0.396	0.540
Phryganea sp.	0.557	0.223
Family: Polycentropodidae, incl. Polycentropus	0.403	0.021
Family: Elmidae, incl. Heterlimnius, Optioservus	-0.556	0.615
Culicoides	0.161	-0.987
Probezzia	0.667	0.733
Sphaeromias sp.	-0.039	0.558
Chironomus	-1.52	0.146
Cryptochironomus	-0.133	-0.828
Demicryptochironomus sp.	0.056	0.651
Dicrotendipes	0.245	-0.067
Microtendipes pedellus	0.468	0.087
Polypedilum sp.	-0.180	-1.35
Stictochironomus	-0.731	-0.586
Pseudochironomus sp.	0.450	0.630
Stempellina sp.	0.011	-1.02
Tanytarsus	0.037	-0.503
Pagastia	0.499	0.003
Potthastia gaedii group	0.143	-1.14
Heterotrissocladius sp.	-0.327	-0.910
Orthocladius complex	-1.02	0.315
Monodiamesa sp.	-0.256	-1.55
Ablabesmyia	0.404	-0.171
Thienemannimyia group	-0.100	-0.794
Procladius	0.158	-0.398
Family: Empididae, incl. Chelifera/Metachela, Clinocera, Hemerodromia, Oreogeton	-1.74	0.800
Family: Coenagrionidae	0.515	0.538
Family: Corduliidae, incl. Epitheca, Somatochlora	0.524	0.575
Order: Amphipoda, incl. Gammarus, Hyalella	0.133	0.173
Class: Arachnida, incl. Acari	-0.050	-0.138
Family: Hydrozetidae	-3.25	1.33
Family: Pisidiidae, incl. Pisidium, Sphaerium	0.186	0.128
Class: Gastropoda, incl. Lymnaeidae, Physidae, Planorbidae, Valvatidae (all collapsed as no identified snails found in 874 gastropods in QUL-48-1)	0.026	0.297
Family: Glossiphoniidae, incl. Helobdella	0.239	0.124
Family: Lumbriculidae	-0.389	0.054
Family: Tubificidae	-0.230	0.053

Table G.19: MANOVA statistics for benthic metrics from Quesnel Lake littoral areas, Mount Polley Mine, 2014.

Effect	Statistic	F-ratio	Hypothesis df	Error df	p-value	Power

[a] Bonferroni post-hoc Test, or Tamhane's T2 Test where variances were found to be heterogenous by Levene's Test

[b] p-value obtained from post-hoc analysis of 1-way ANOVA among all areas (post-hoc analyses protected for multiple comparisons)

[c] Magnitude calculated by comparing the difference between the reference area (I) and exposure area (J) means to the reference area (I) standard deviation (SD) [(exposure mean - reference mean) / standard deviation of the reference mean]

[d] Minimum effect size detectable calculated based on variance as square root of MSE from ANOVA and alpha = beta = 0.10. Minimum effect size reported as the minimum number of standard deviations detectable based on reference area standard deviation.

Table G.23: Descriptive statistics of benthic metrics for Quesnel Lake profundal sampling areas, Mount Polley Mine, 2014.

		Sig. (2-tailed)	0.6075	0.3307	0.1352	0.5452

Significant correlation; p-value < 0.0001 (Bonferroni corrected p-value for 408 comparisons among Table 6.7 and Appendix Table I.1).
Correlation scatterplot inspected; p <0.01.

[1] Values < method detection limit (MDL) were used at the MDL for calculations. Normalized survival and growth are relative to corresponding laboratory controls.

Note: n=15 for all correlations.

Table I.2: Spearman's Rank Correlation results for correlation of toxicity test results and benthic invertebrate community metrics in Polley and Bootjack Lake deep sampling areas, Mount Polley Mine, 2014 [1].

Physical/Chemical Parameter		Correlation Parameter	Toxicity Endpoints			
			Hyalella azteca		*Chironomus dilutus*

[a] Bonferroni post-hoc Test, or Dunnet's T3 Test where variances were found to be heterogenous by Levene's Test

[b] Due to low replication (3 per area) T-Tests are used as post-hoc test of significance between areas - Bonferroni and Tamhane post-hoc tests are reported for interest only.

[c] Magnitude calculated by comparing the difference between the control area and exposed area means to the control area standard deviation (SD) [(exposed mean - control mean) / standard deviation of the control mean]

[d] Minimum effect size detectable calculated based on variance as square root of MSE from ANOVA and alpha = beta = 0.10.
Minimum effect size reported as the minimum number of standard deviations detectable based on reference area standard deviation.

Highlighted values indicate significance at the *p* < 0.10 level.

Table I.10: Statistical comparison summary of primary benthic invertebrate community metrics for reference area CAR and six Quesnel River areas. Metrics were calculated at the family level of taxonomic resolution, Mount Polley Mine, 2014.

[a] Bonferroni post-hoc Test, or Dunnet's T3 Test where variances were found to be heterogenous by Levene's Test

[b] Due to low replication (3 per area) T-Tests are used as post-hoc test of significance between areas - Bonferroni and Tamhane post-hoc tests are reported for interest only.

[c] Magnitude calculated by comparing the difference between the control area and exposed area means to the control area standard deviation (SD) [(exposed mean - control mean) / standard deviation of the control mean]

[d] Minimum effect size detectable calculated based on variance as square root of MSE from ANOVA and alpha = beta = 0.10.
Minimum effect size reported as the minimum number of standard deviations detectable based on reference area standard deviation.

Highlighted values indicate significance at the *p* < 0.10 level.

Table I.11: Statistical comparison summary of benthic invertebrate major group proportion for reference area CAR and six Quesnel River areas. Metrics were calculated at the family level of taxonomic resolution, Mount Polley Mine, 2014.

[a] Bonferroni post-hoc Test, or Dunnet's T3 Test where variances were found to be heterogenous by Levene's Test

[b] Due to low replication (3 per area) T-Tests are used as post-hoc test of significance between areas - Bonferroni and Tamhane post-hoc tests are reported for interest only.

[c] Magnitude calculated by comparing the difference between the control area and exposed area means to the control area standard deviation (SD) [(exposed mean - control mean) / standard deviation of the control mean]

[d] Minimum effect size detectable calculated based on variance as square root of MSE from ANOVA and alpha = beta = 0.10.
Minimum effect size reported as the minimum number of standard deviations detectable based on reference area standard deviation.

[e] No observations in either Area1 or Area2; therefore, no statistic possible.

[f] Zero variance in Area1; therefore, calculation not possible.

Highlighted values indicate significance at the *p* < 0.10 level.

Table I.12: Statistical comparison summary of benthic invertebrate major group proportion for reference area CLR and six Quesnel River areas. Metrics were calculated at the family level of taxonomic resolution, Mount Polley Mine, 2014.

[a] Bonferroni post-hoc Test, or Dunnet's T3 Test where variances were found to be heterogenous by Levene's Test
[b] Due to low replication (3 per area) T-Tests are used as post-hoc test of significance between areas - Bonferroni and Tamhane post-hoc tests are reported for interest only.
[c] Magnitude calculated by comparing the difference between the control area and exposed area means to the control area standard deviation (SD) [(exposed mean - control mean) / standard deviation of the control mean]
[d] Minimum effect size detectable calculated based on variance as square root of MSE from ANOVA and alpha = beta = 0.10. Minimum effect size reported as the minimum number of standard deviations detectable based on reference area standard deviation.
[e] No observations in either Area1 or Area2; therefore, no statistic possible.
[f] Zero variance in Area1; therefore, calculation not possible.
Highlighted values indicate significance at the *p* < 0.10 level.

[a] Bonferroni post-hoc Test, or Dunnet's T3 Test where variances were found to be heterogenous by Levene's Test

[b] Due to low replication (3 per area) T-Tests are used as post-hoc test of significance between areas - Bonferroni and Tamhane post-hoc tests are reported for interest only.

[c] Magnitude calculated by comparing the difference between the control area and exposed area means to the control area standard deviation (SD) [(exposed mean - control mean) / standard deviation of the control mean]

[d] Minimum effect size detectable calculated based on variance as square root of MSE from ANOVA and alpha = beta = 0.10. Minimum effect size reported as the minimum number of standard deviations detectable based on reference area standard deviation.

[e] All observations at MLD in both areas; therefore, no statistic possible.

[f] Zero variance in Area1; therefore, calculation not possible.

Highlighted values indicate significance at the *p* < 0.10 level.

[a] Bonferroni post-hoc Test, or Dunnet's T3 Test where variances were found to be heterogenous by Levene's Test

[b] Due to low replication (3 per area) T-Tests are used as post-hoc test of significance between areas - Bonferroni and Tamhane post-hoc tests are reported for interest only.

[c] Magnitude calculated by comparing the difference between the control area and exposed area means to the control area standard deviation (SD) [(exposed mean - control mean) / standard deviation of the control mean]

[d] Minimum effect size detectable calculated based on variance as square root of MSE from ANOVA and alpha = beta = 0.10. Minimum effect size reported as the minimum number of standard deviations detectable based on reference area standard deviation.

[e] All observations at MLD in both areas; therefore, no statistic possible.

[f] Zero variance in Area1; therefore, calculation not possible.

Highlighted values indicate significance at the *p* < 0.10 level.

[a] Bonferroni post-hoc Test, or Dunnet's T3 Test where variances were found to be heterogenous by Levene's Test

[b] Due to low replication (3 per area) T-Tests are used as post-hoc test of significance between areas - Bonferroni and Tamhane post-hoc tests are reported for interest only.

[c] Magnitude calculated by comparing the difference between the control area and exposed area means to the control area standard deviation (SD) [(exposed mean - control mean) / standard deviation of the control mean]

[d] Minimum effect size detectable calculated based on variance as square root of MSE from ANOVA and alpha = beta = 0.10. Minimum effect size reported as the minimum number of standard deviations detectable based on reference area standard deviation.

[e] All observations at MLD in both areas; therefore, no statistic possible.

[f] Zero variance in Area1; therefore, calculation not possible.

Highlighted values indicate significance at the $p < 0.10$ level.

Table I.21: PCA results of Perlidae tissue metal and metalloid concentrations. Eigen value, percent variance explained, Monte Carlo randomization p-values of axis significance, and area scores of three reference and six Quesnel River areas, Mount Polley Mine, 2014.

[a] Bonferroni post-hoc Test, or Dunnet's T3 Test where variances were found to be heterogenous by Levene's Test

[b] Due to low replication (3 per area) T-Tests are used as post-hoc test of significance between areas - Bonferroni and Tamhane post-hoc tests are reported for interest only.

[c] Magnitude calculated by comparing the difference between the control area and exposed area means to the control area standard deviation (SD) [(exposed mean - control mean) / standard deviation of the control mean]

[d] Minimum effect size detectable calculated based on variance as square root of MSE from ANOVA and alpha = beta = 0.10. Minimum effect size reported as the minimum number of standard deviations detectable based on reference area standard deviation.

[e] All observations at MLD in both areas; therefore, no statistic possible.

[f] Zero variance in Area1; therefore, calculation not possible.

Highlighted values indicate significance at the *p* < 0.10 level.

Table I.24: Statistical comparison summary of perlidae metal and metalloid tissue concentration for reference area CAR and six Quesnel River areas, Mount Polley Mine, 2014.

[a] Bonferroni post-hoc Test, or Dunnet's T3 Test where variances were found to be heterogenous by Levene's Test

[b] Due to low replication (3 per area) T-Tests are used as post-hoc test of significance between areas - Bonferroni and Tamhane post-hoc tests are reported for interest only.

[c] Magnitude calculated by comparing the difference between the control area and exposed area means to the control area standard deviation (SD) [(exposed mean - control mean) / standard deviation of the control mean]

[d] Minimum effect size detectable calculated based on variance as square root of MSE from ANOVA and alpha = beta = 0.10. Minimum effect size reported as the minimum number of standard deviations detectable based on reference area standard deviation.

[e] All observations at MLD in both areas; therefore, no statistic possible.

[f] Zero variance in Area1; therefore, calculation not possible.

Highlighted values indicate significance at the *p* < 0.10 level.

Table I.25: Spearman's Rank correlation of metal and metalloid concentrations between whole community benthic invertebrate tissue and Perlidae only tissue from river sampling areas, Mount Polley Mine, 2014.

Statistic	r	p
Al	0.541	0.006

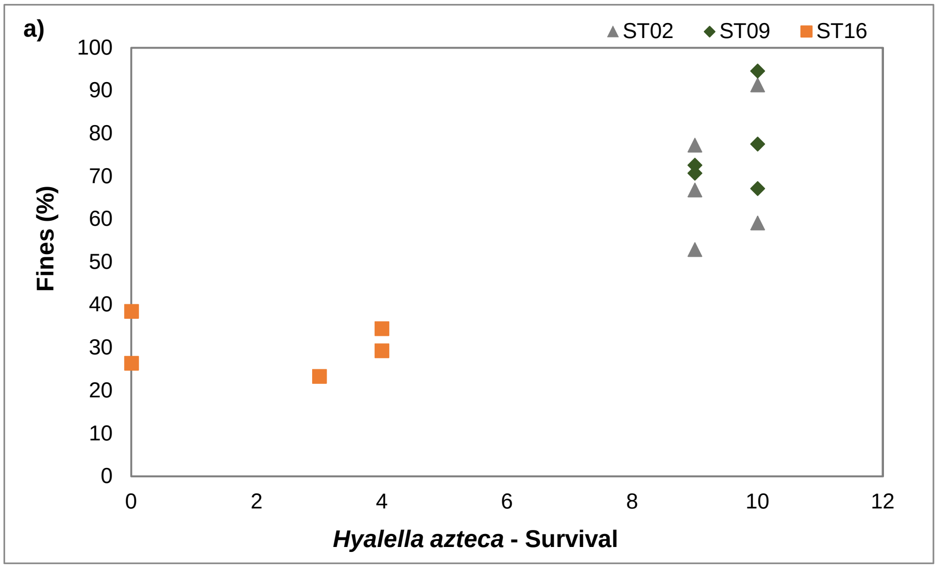
(grey box) indicates a p-value below 0.05.



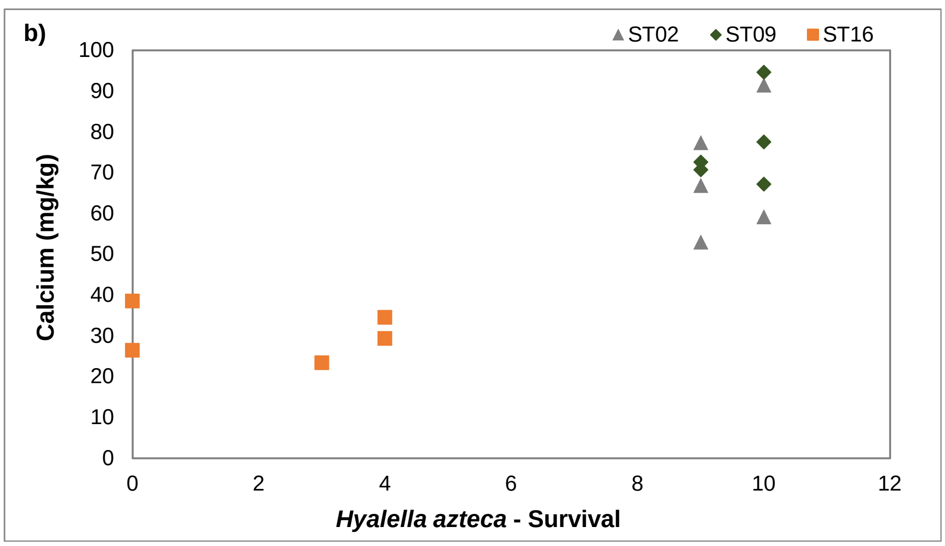


Figure I.1: Scatterplots of significant Spearman's correlation relationships ($p < 0.0006$) between toxicity endpoints and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Hollow symbols indicate values < MDL.

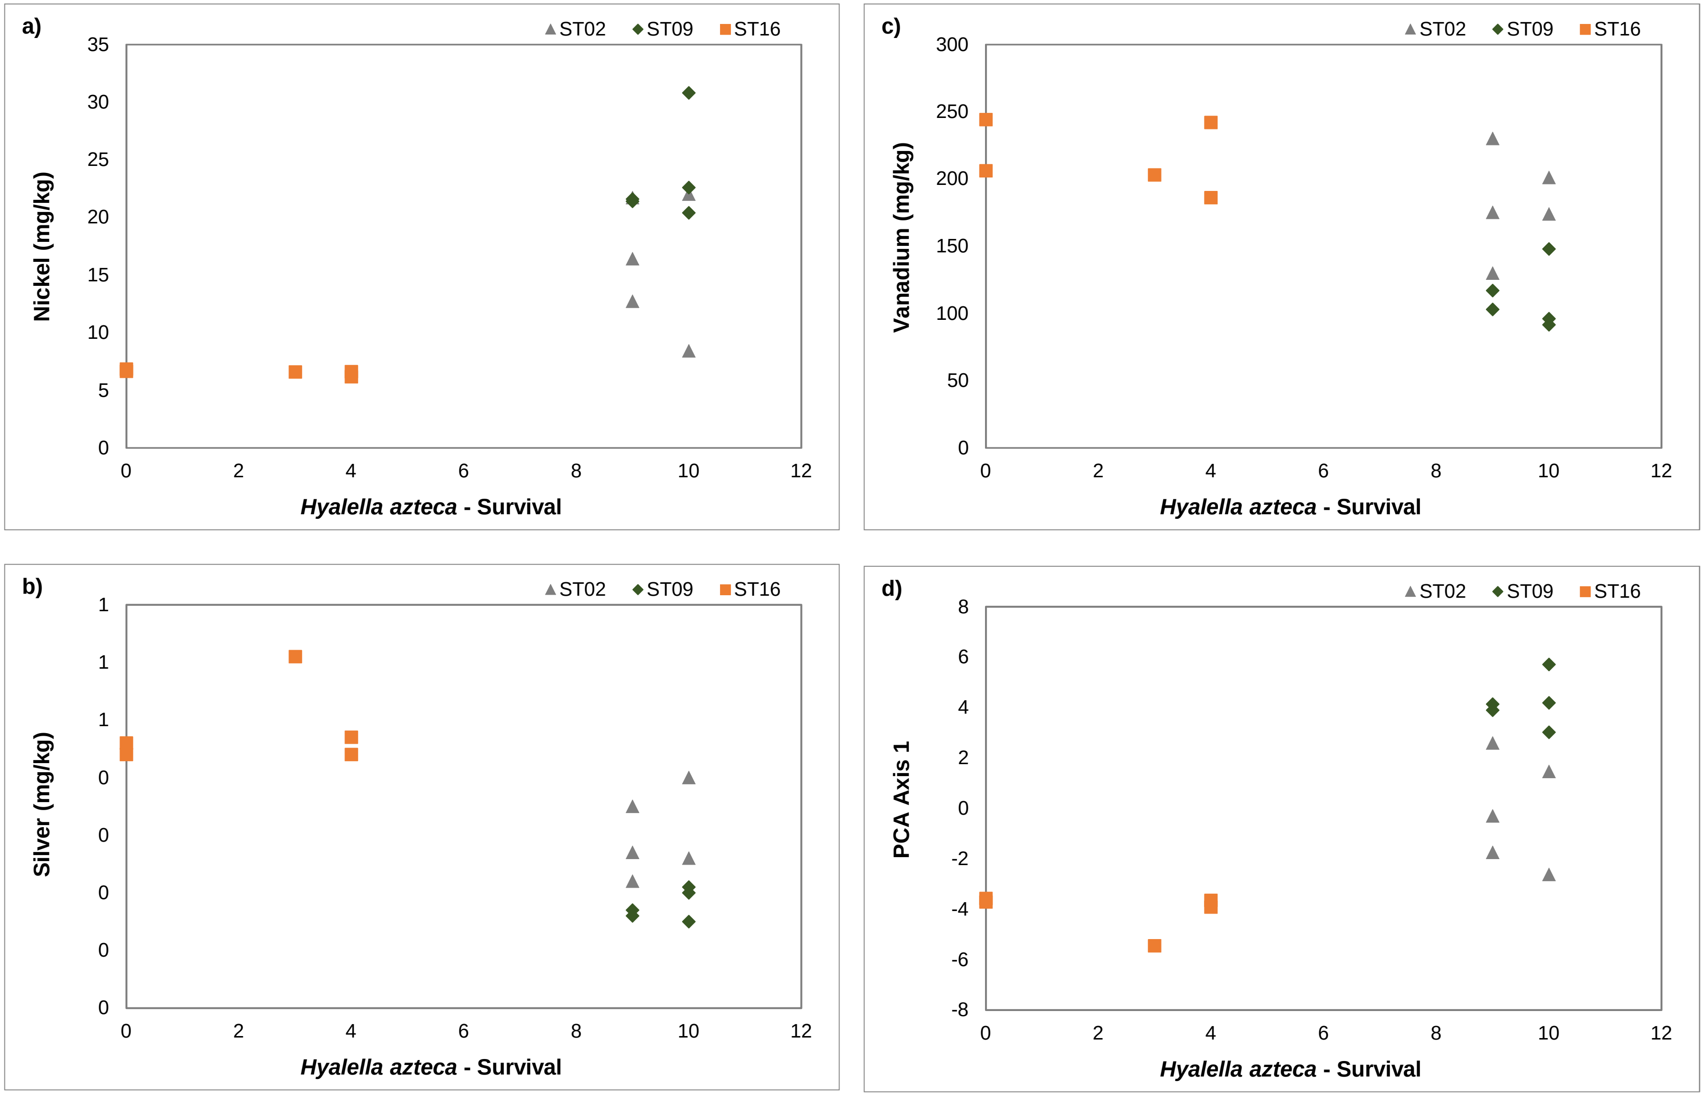

Figure I.2: Scatterplots of significant Spearman's correlation relationships ($p < 0.01$) between toxicity endpoints and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Hollow symbols indicate values < MDL.

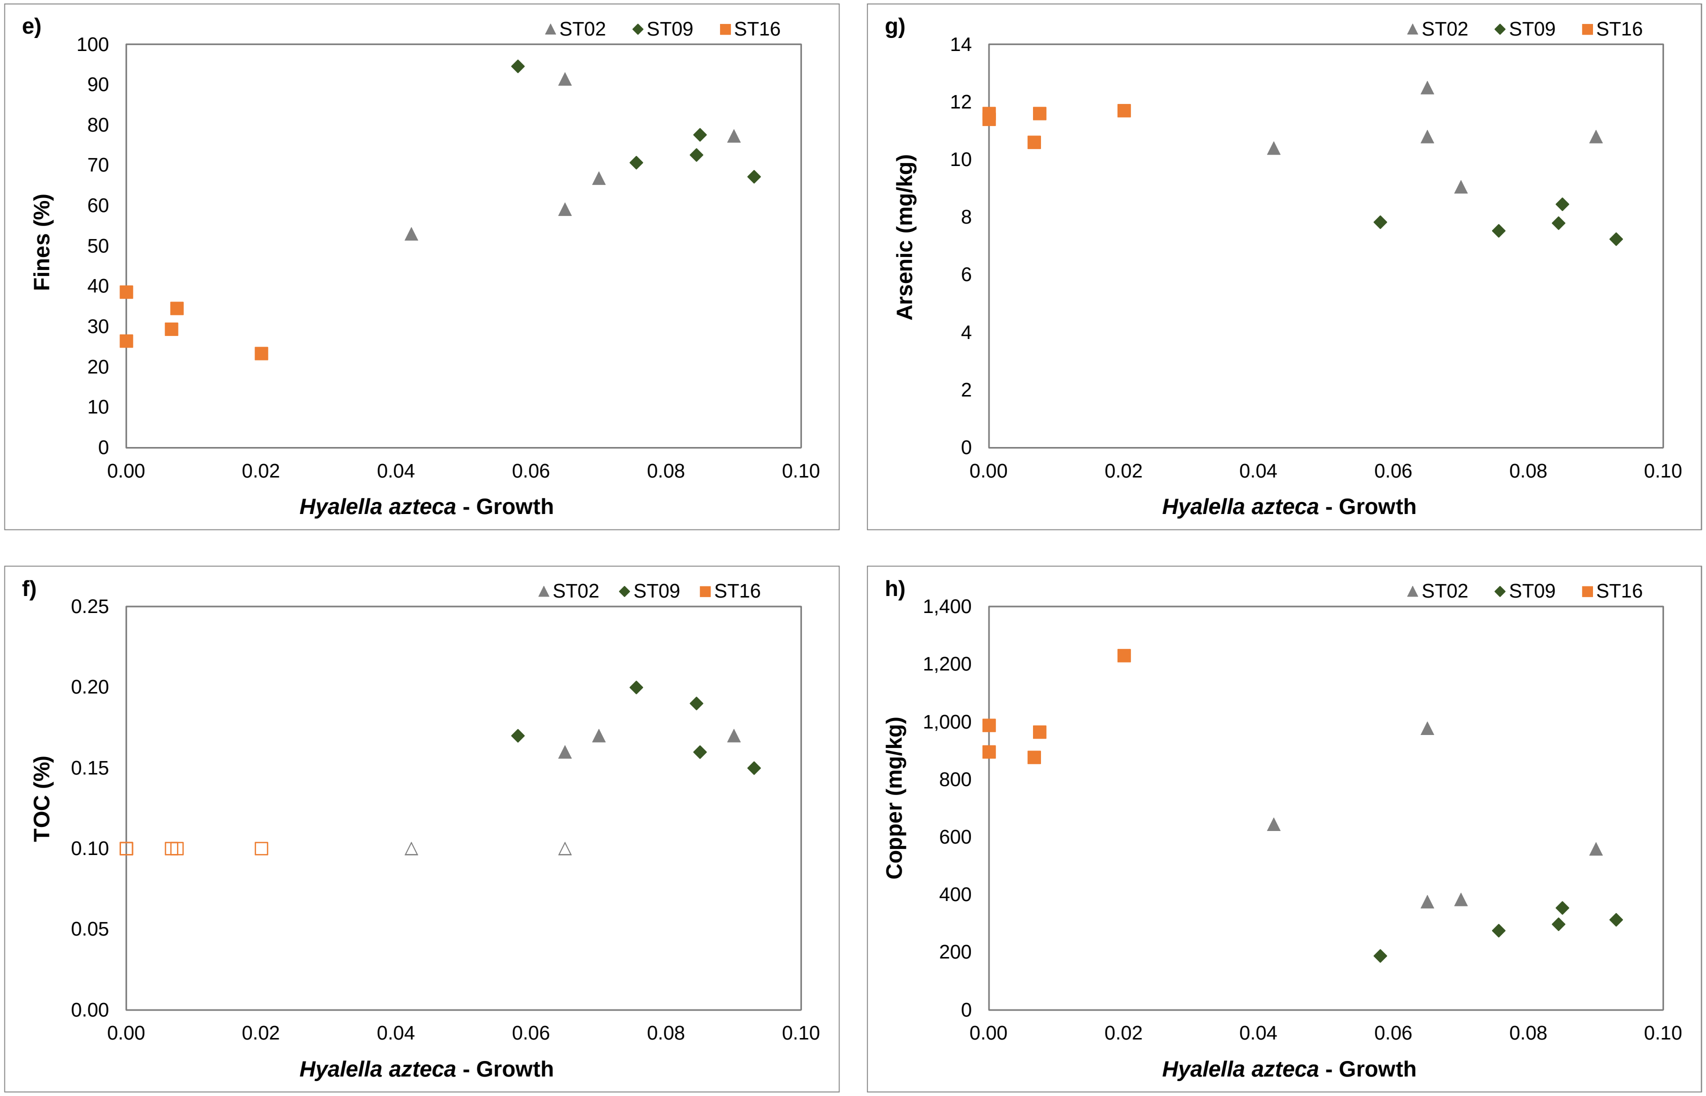

Figure I.2: Scatterplots of significant Spearman's correlation relationships ($p < 0.01$) between toxicity endpoints and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Hollow symbols indicate values < MDL.

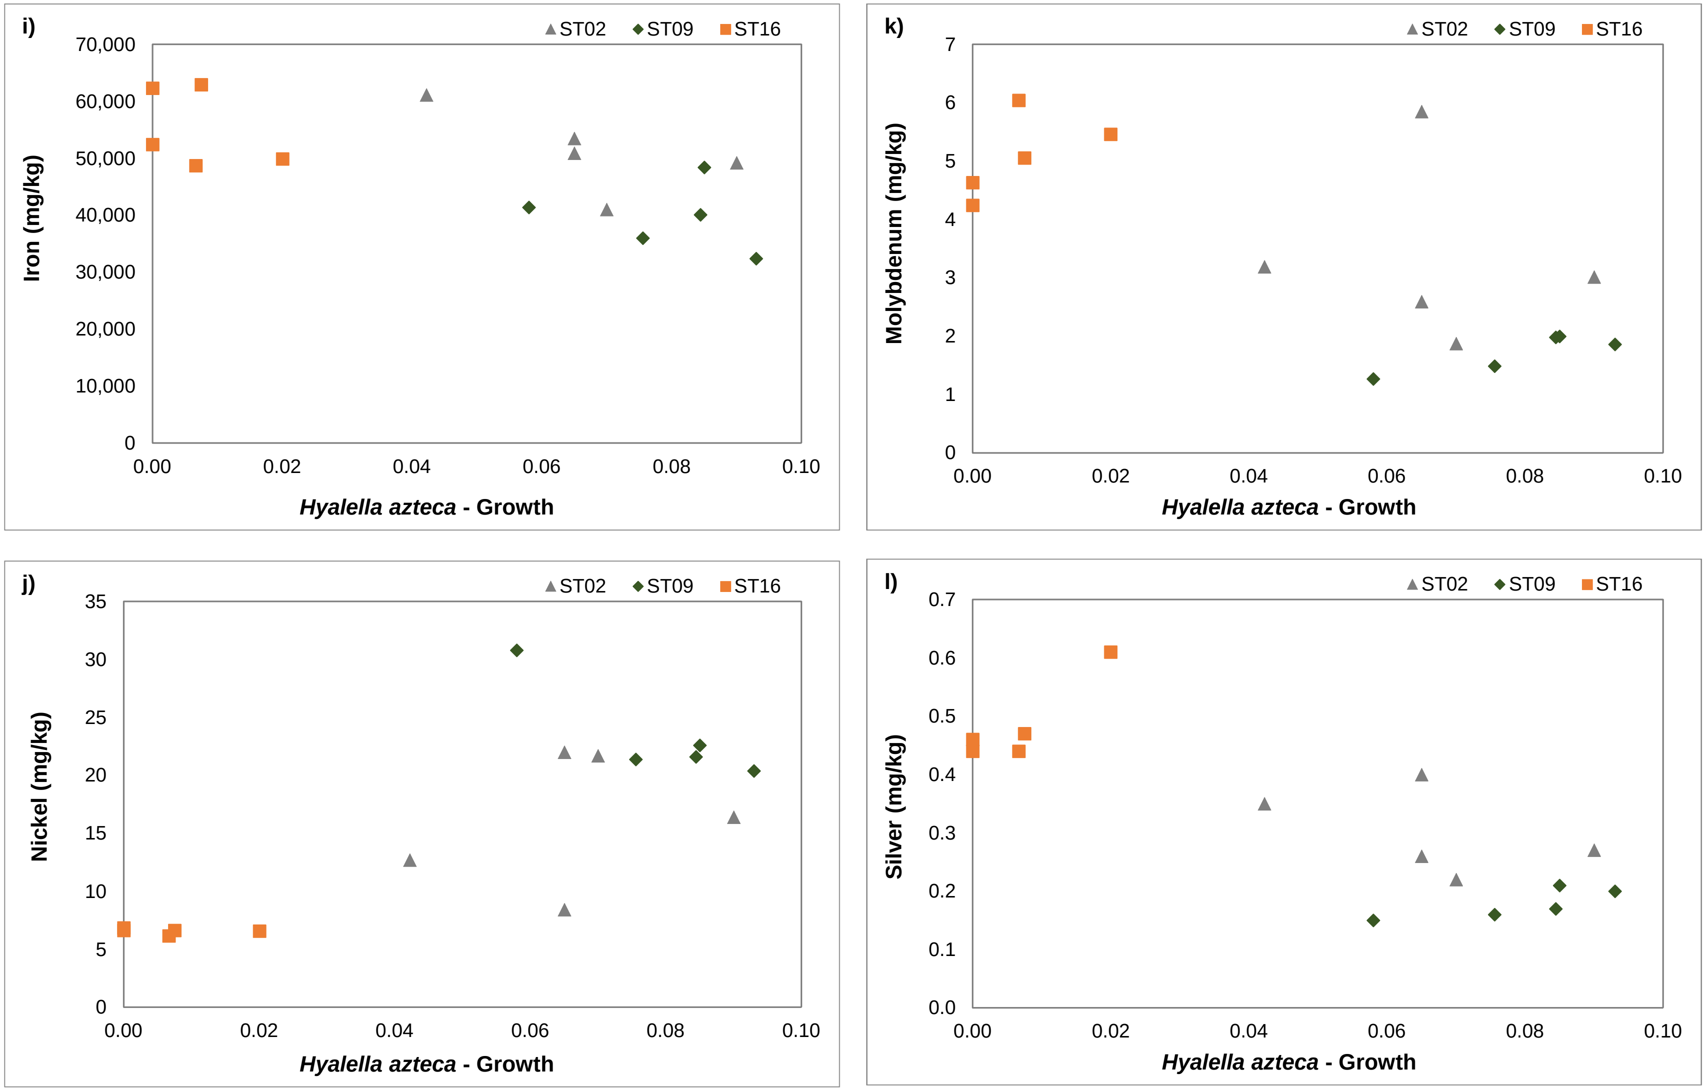

Figure I.2: Scatterplots of significant Spearman's correlation relationships ($p < 0.01$) between toxicity endpoints and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Hollow symbols indicate values < MDL.

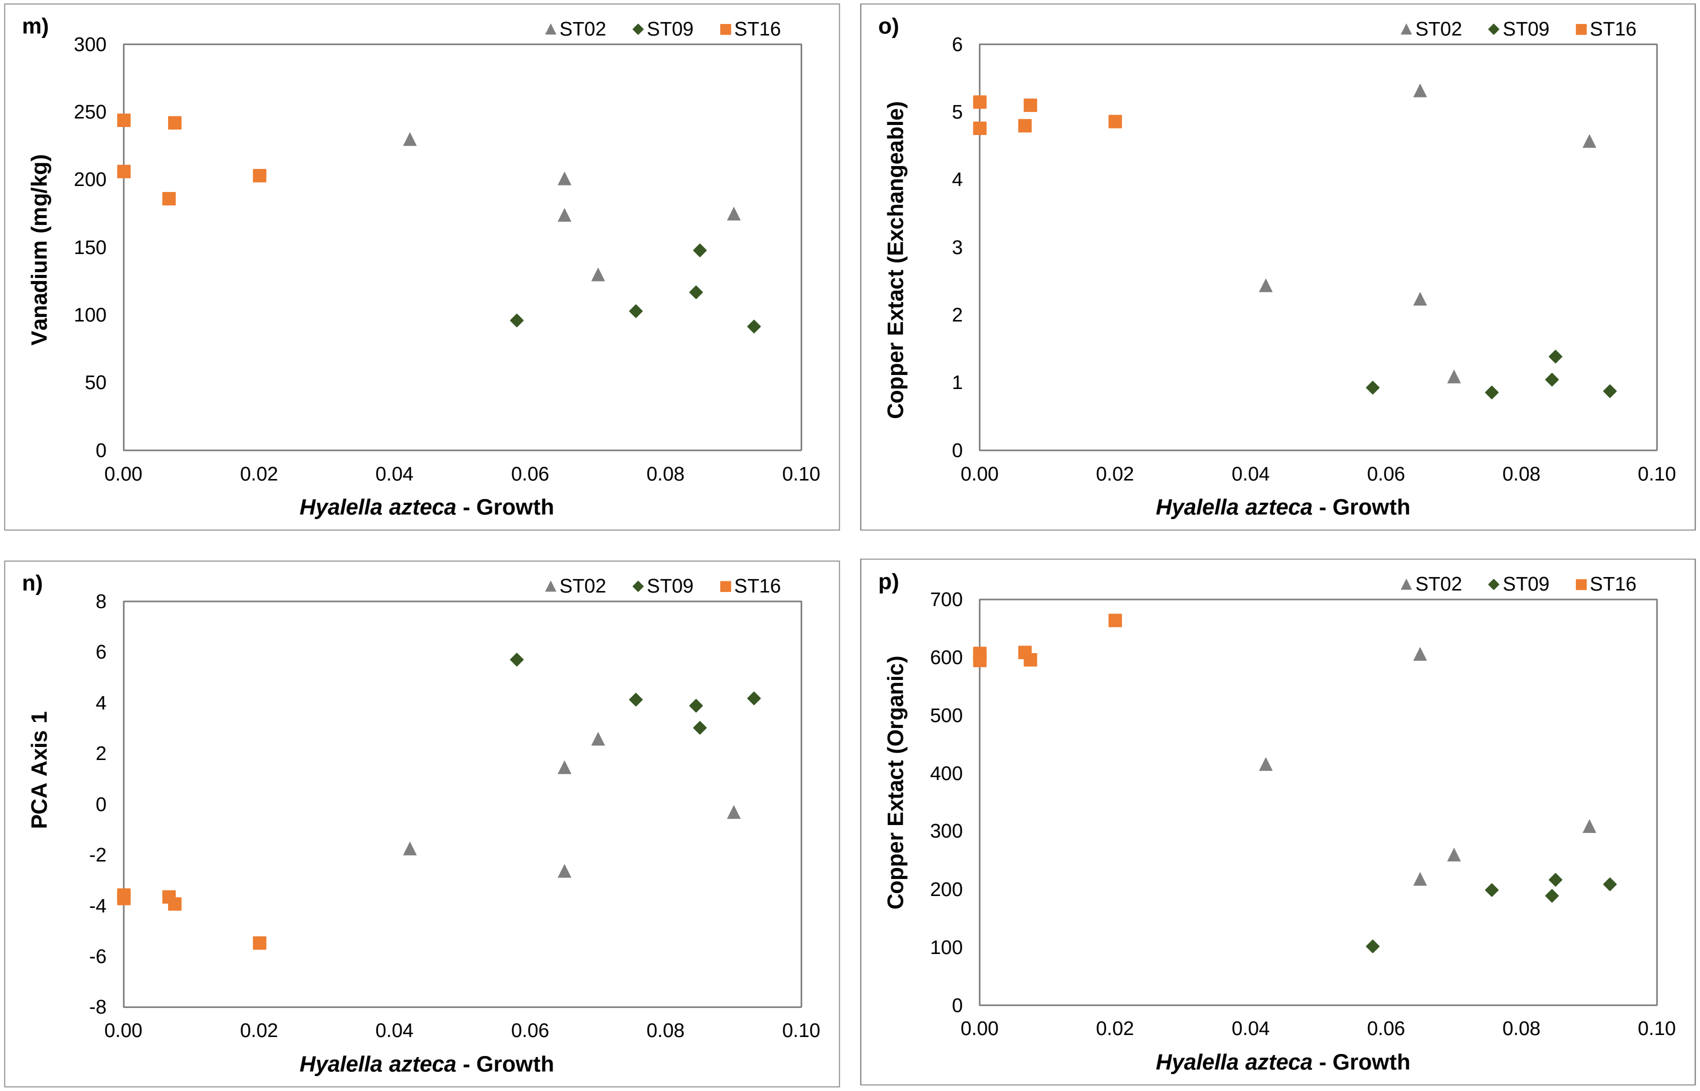

Figure I.2: Scatterplots of significant Spearman's correlation relationships ($p < 0.01$) between toxicity endpoints and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Hollow symbols indicate values < MDL.

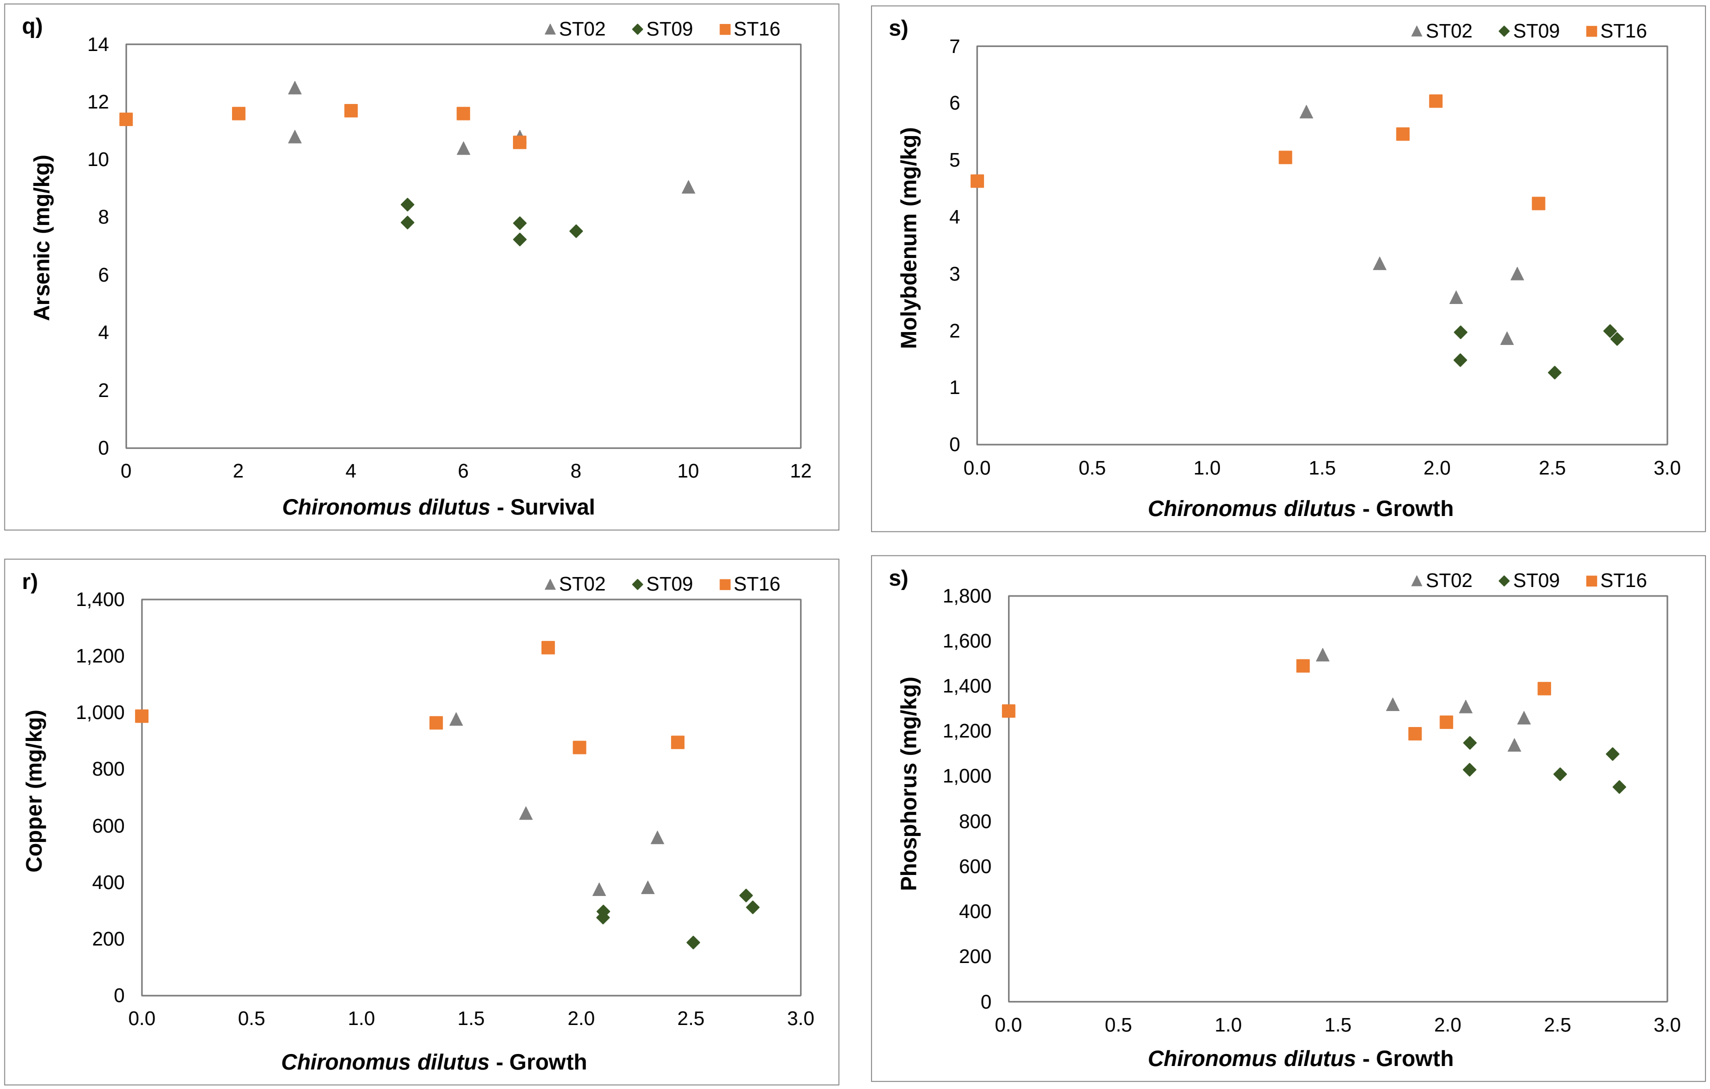

Figure I.2: Scatterplots of significant Spearman's correlation relationships (p < 0.01) between toxicity endpoints and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Hollow symbols indicate values < MDL.

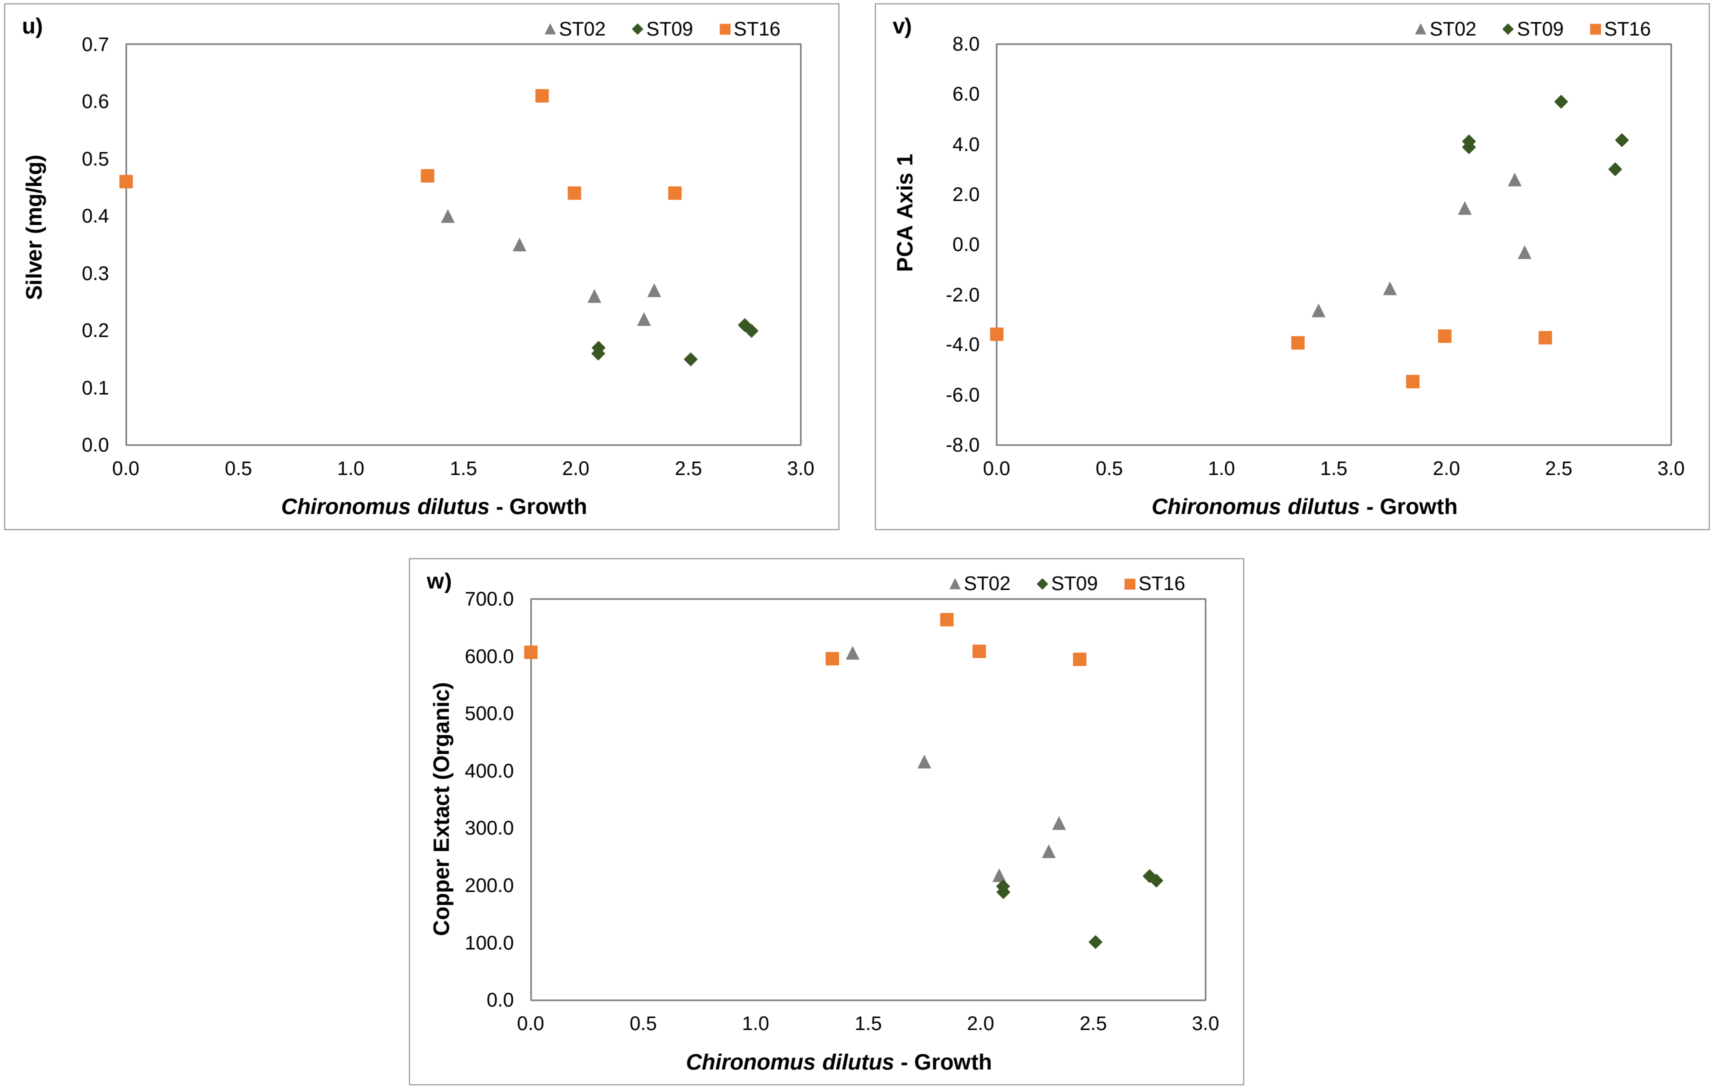

Figure I.2: Scatterplots of significant Spearman's correlation relationships ($p < 0.01$) between toxicity endpoints and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Hazeltine Creek sampling areas, Mount Polley Mine, 2014. Hollow symbols indicate values < MDL.

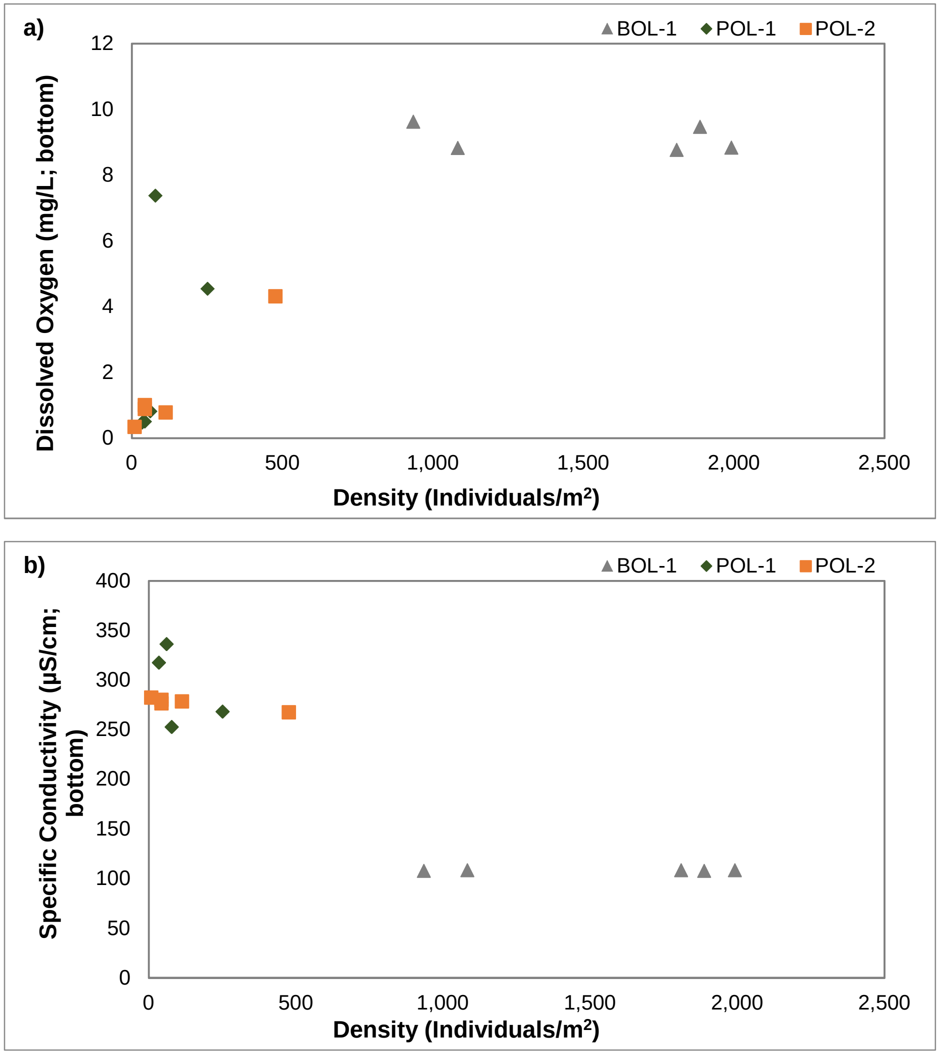

Figure I.3: Scatterplots of significant Spearman's correlation relationships ($p < 0.0001$) between benthic invertebrate community metrics and water in-situ measures, Mount Polley Mine, 2014. Polley and Bootjack Lake mid-depth sampling areas.

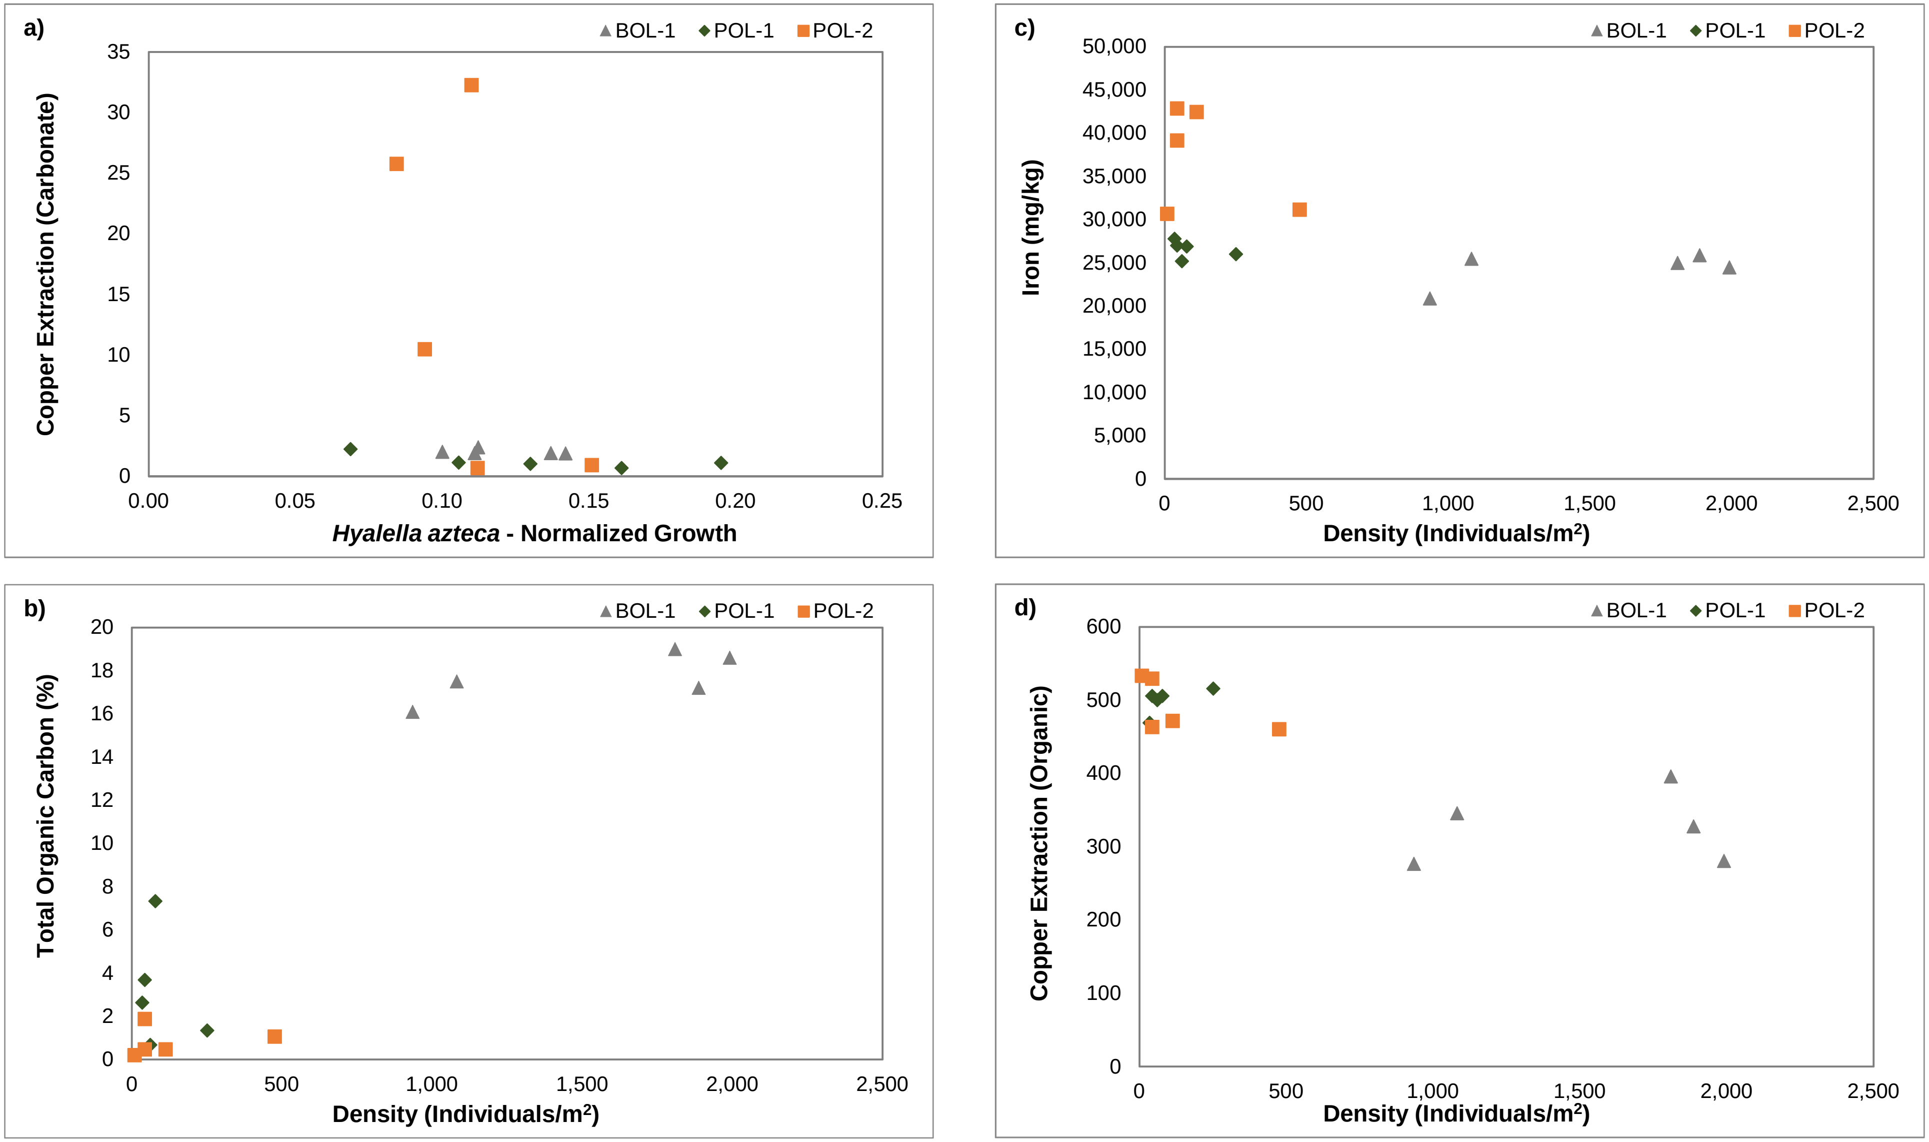

Figure I.4: Scatterplots of Spearman's correlation relationships ($p<0.01$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake mid-depth sampling areas.

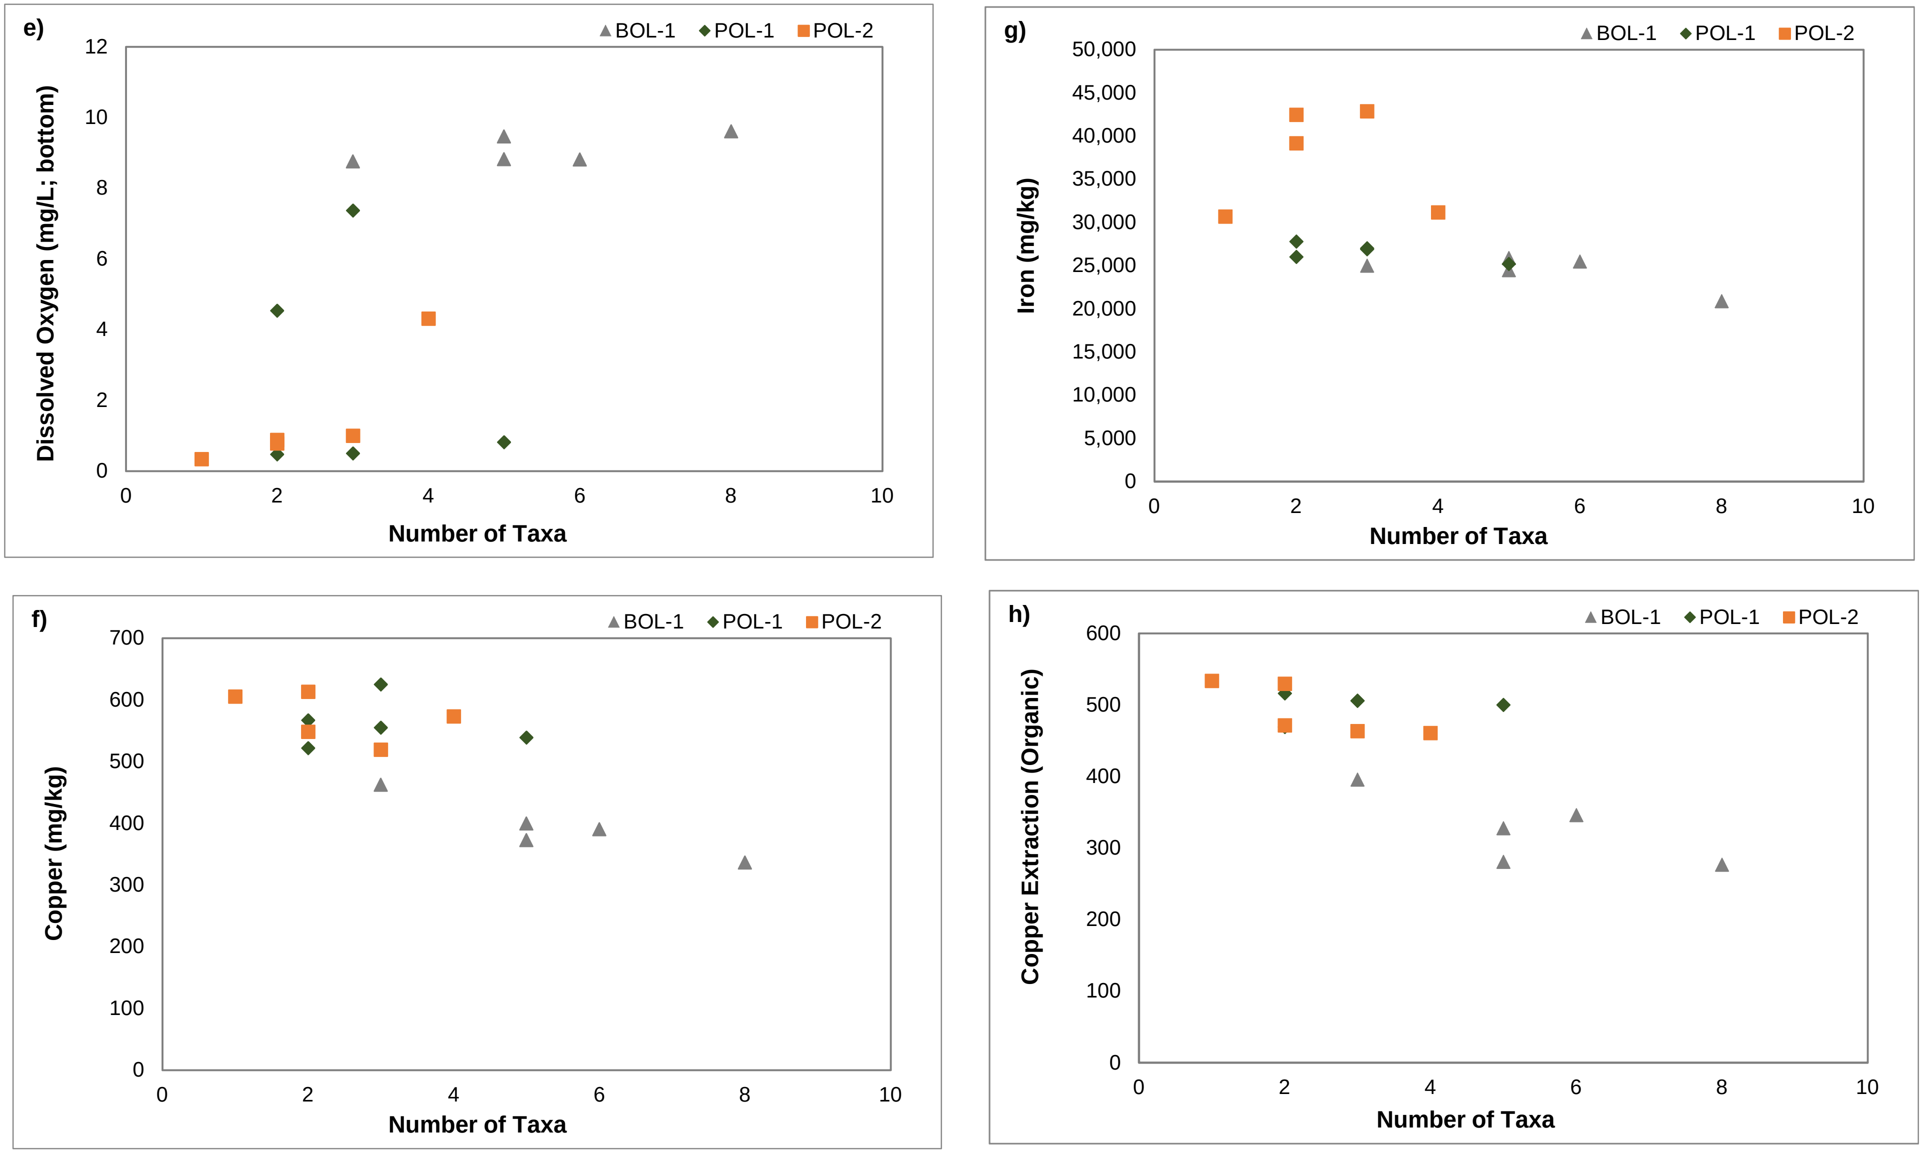

Figure I.4: Scatterplots of Spearman's correlation relationships (p<0.01) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake mid-depth sampling areas.

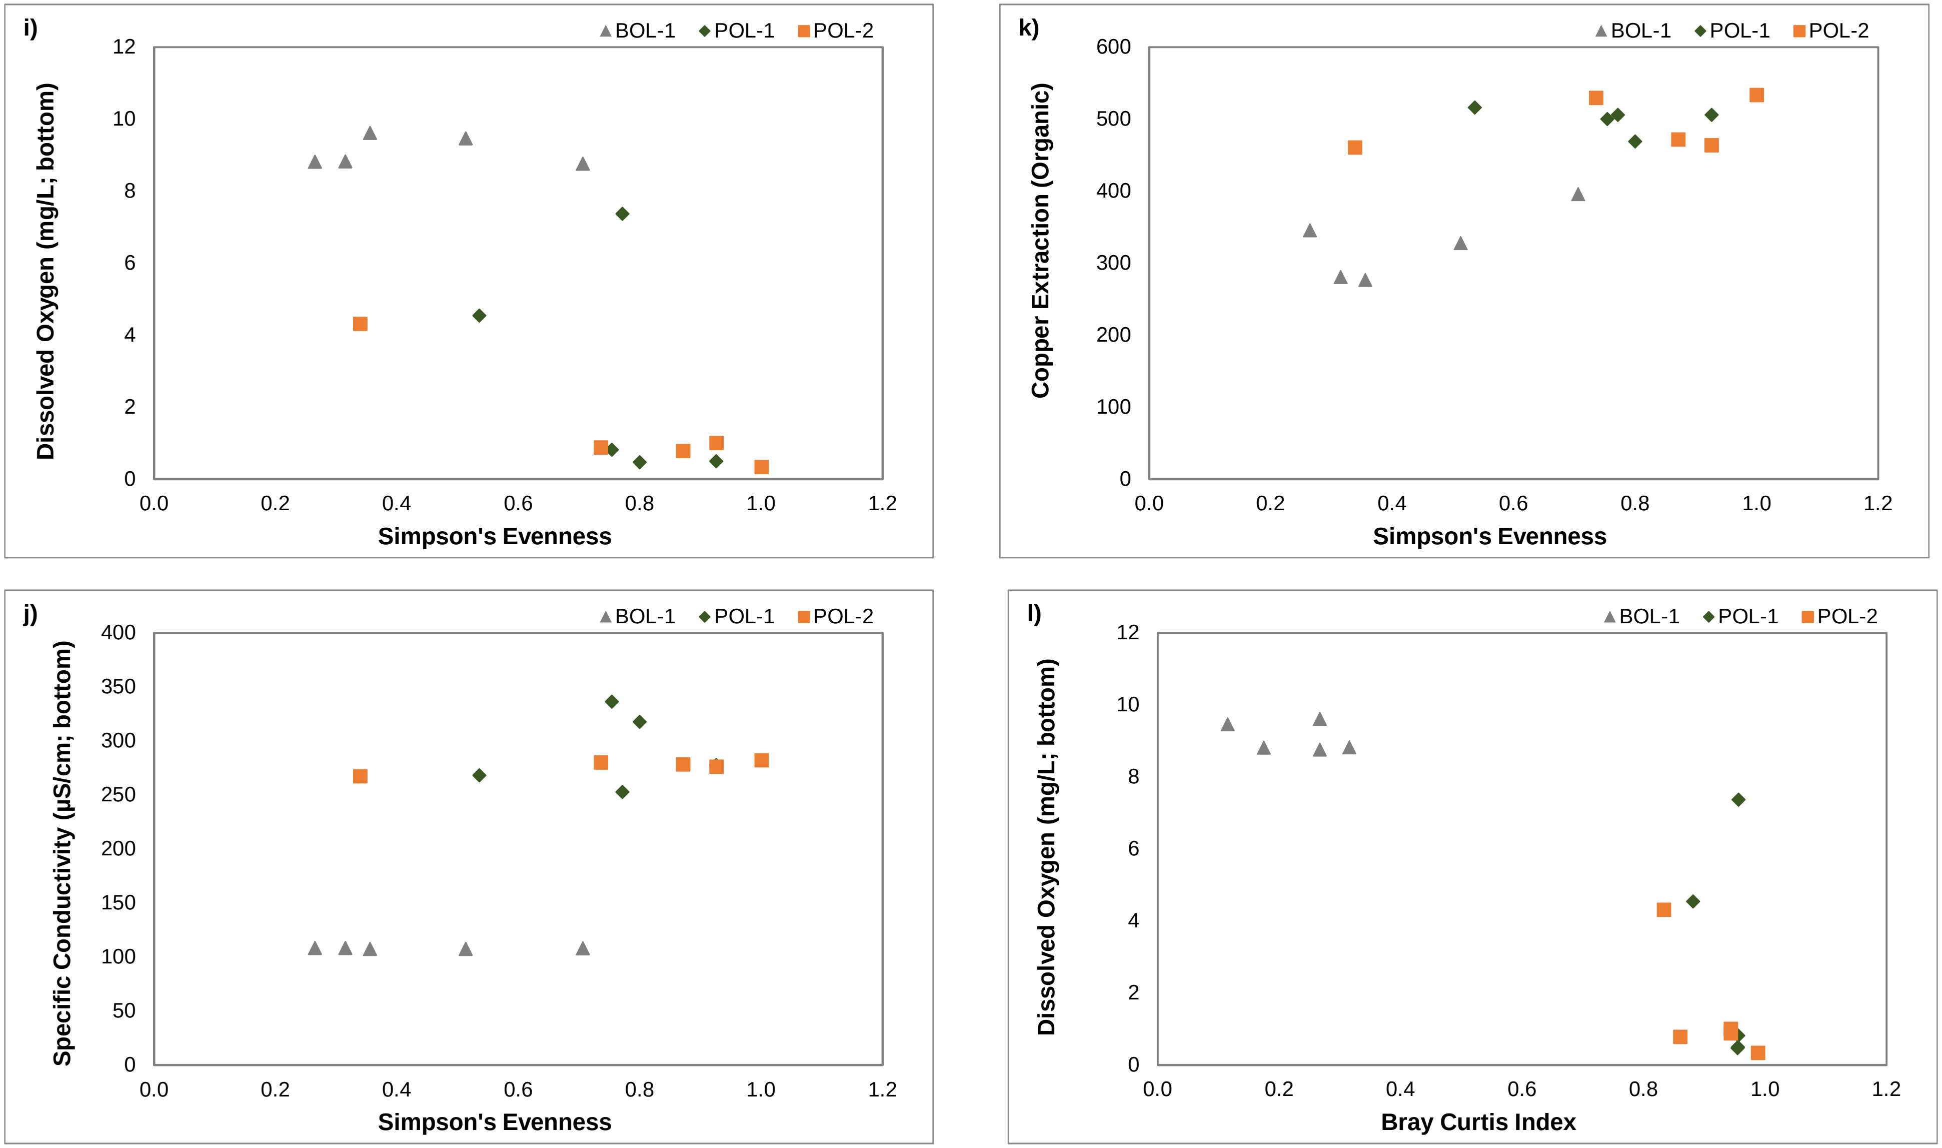

Figure I.4: Scatterplots of Spearman's correlation relationships ($p<0.01$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake mid-depth sampling areas.

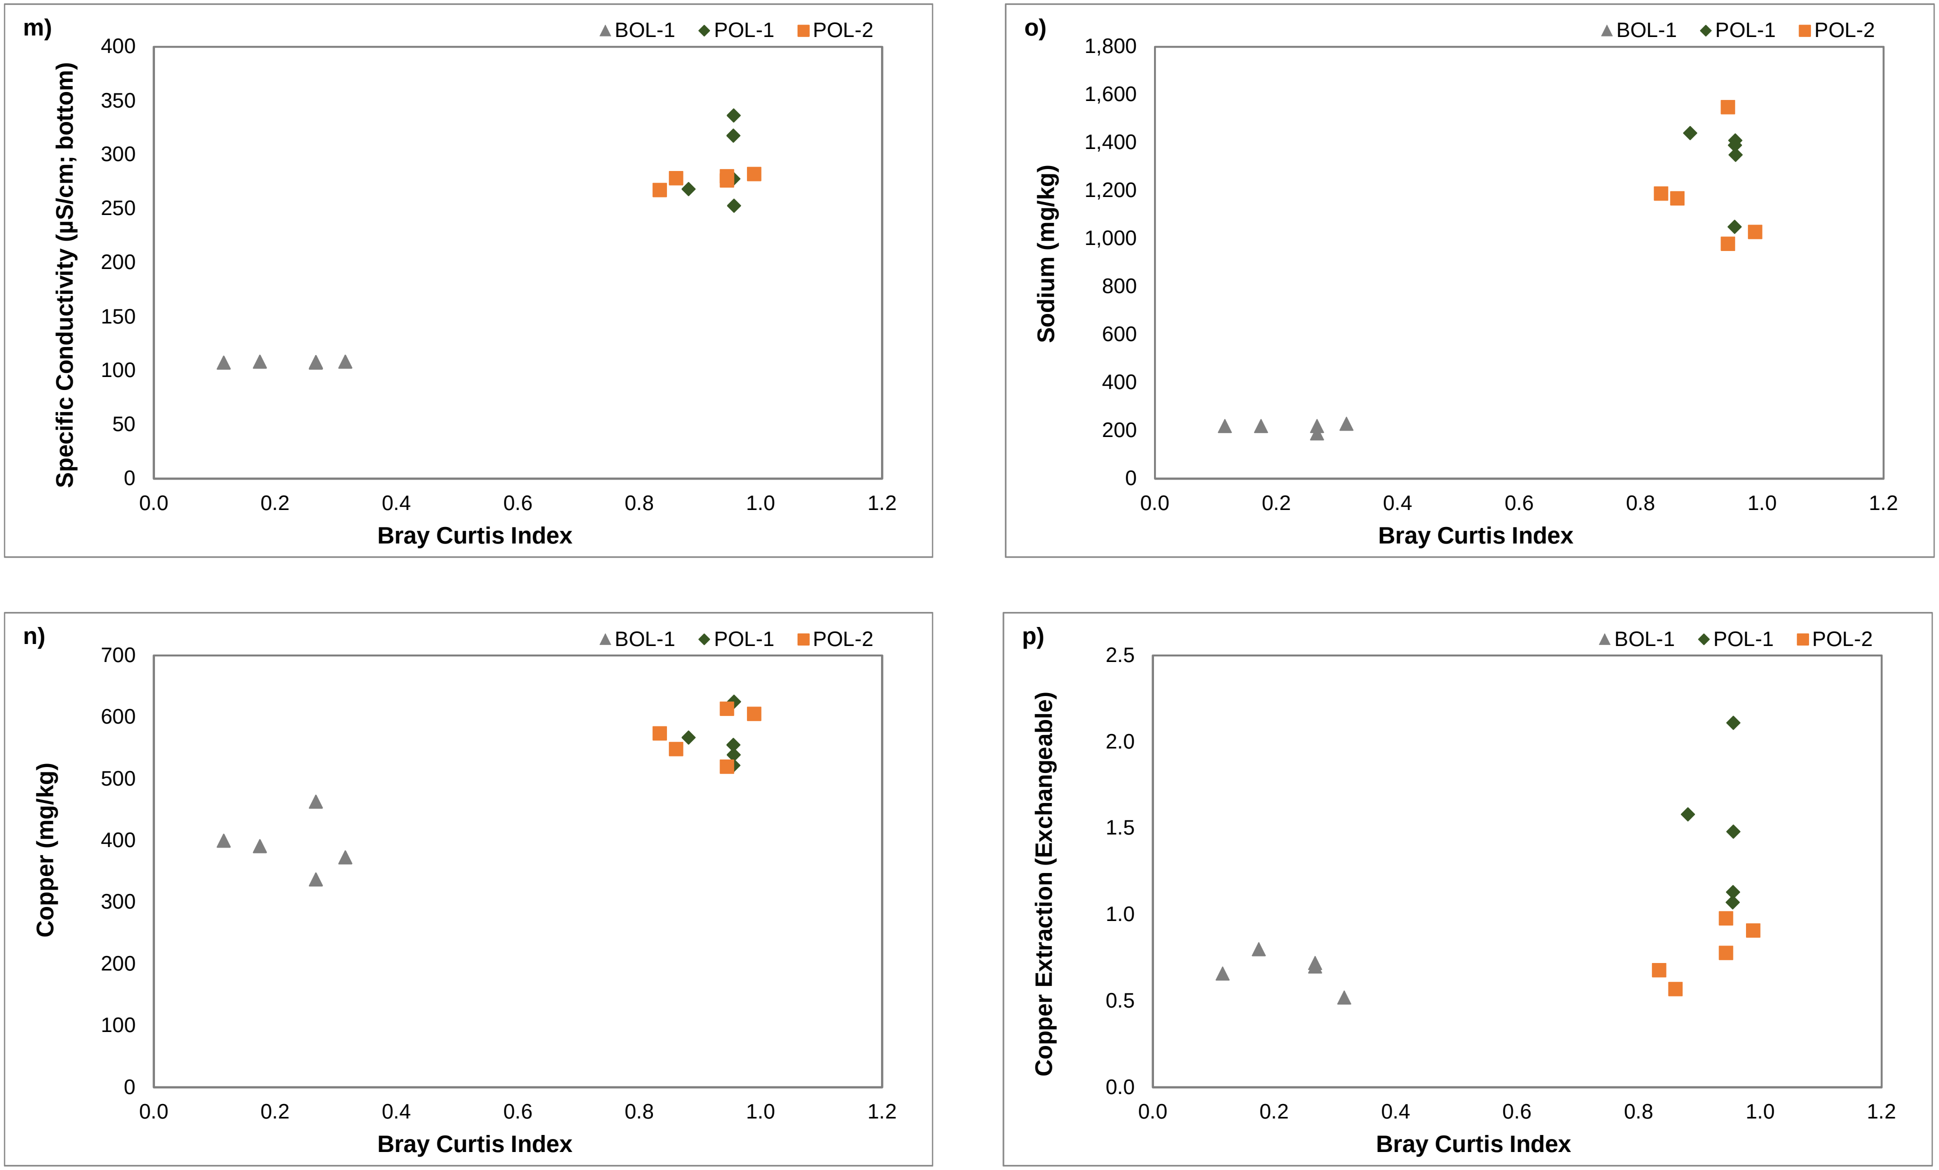

Figure I.4: Scatterplots of Spearman's correlation relationships ($p<0.01$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake mid-depth sampling areas.

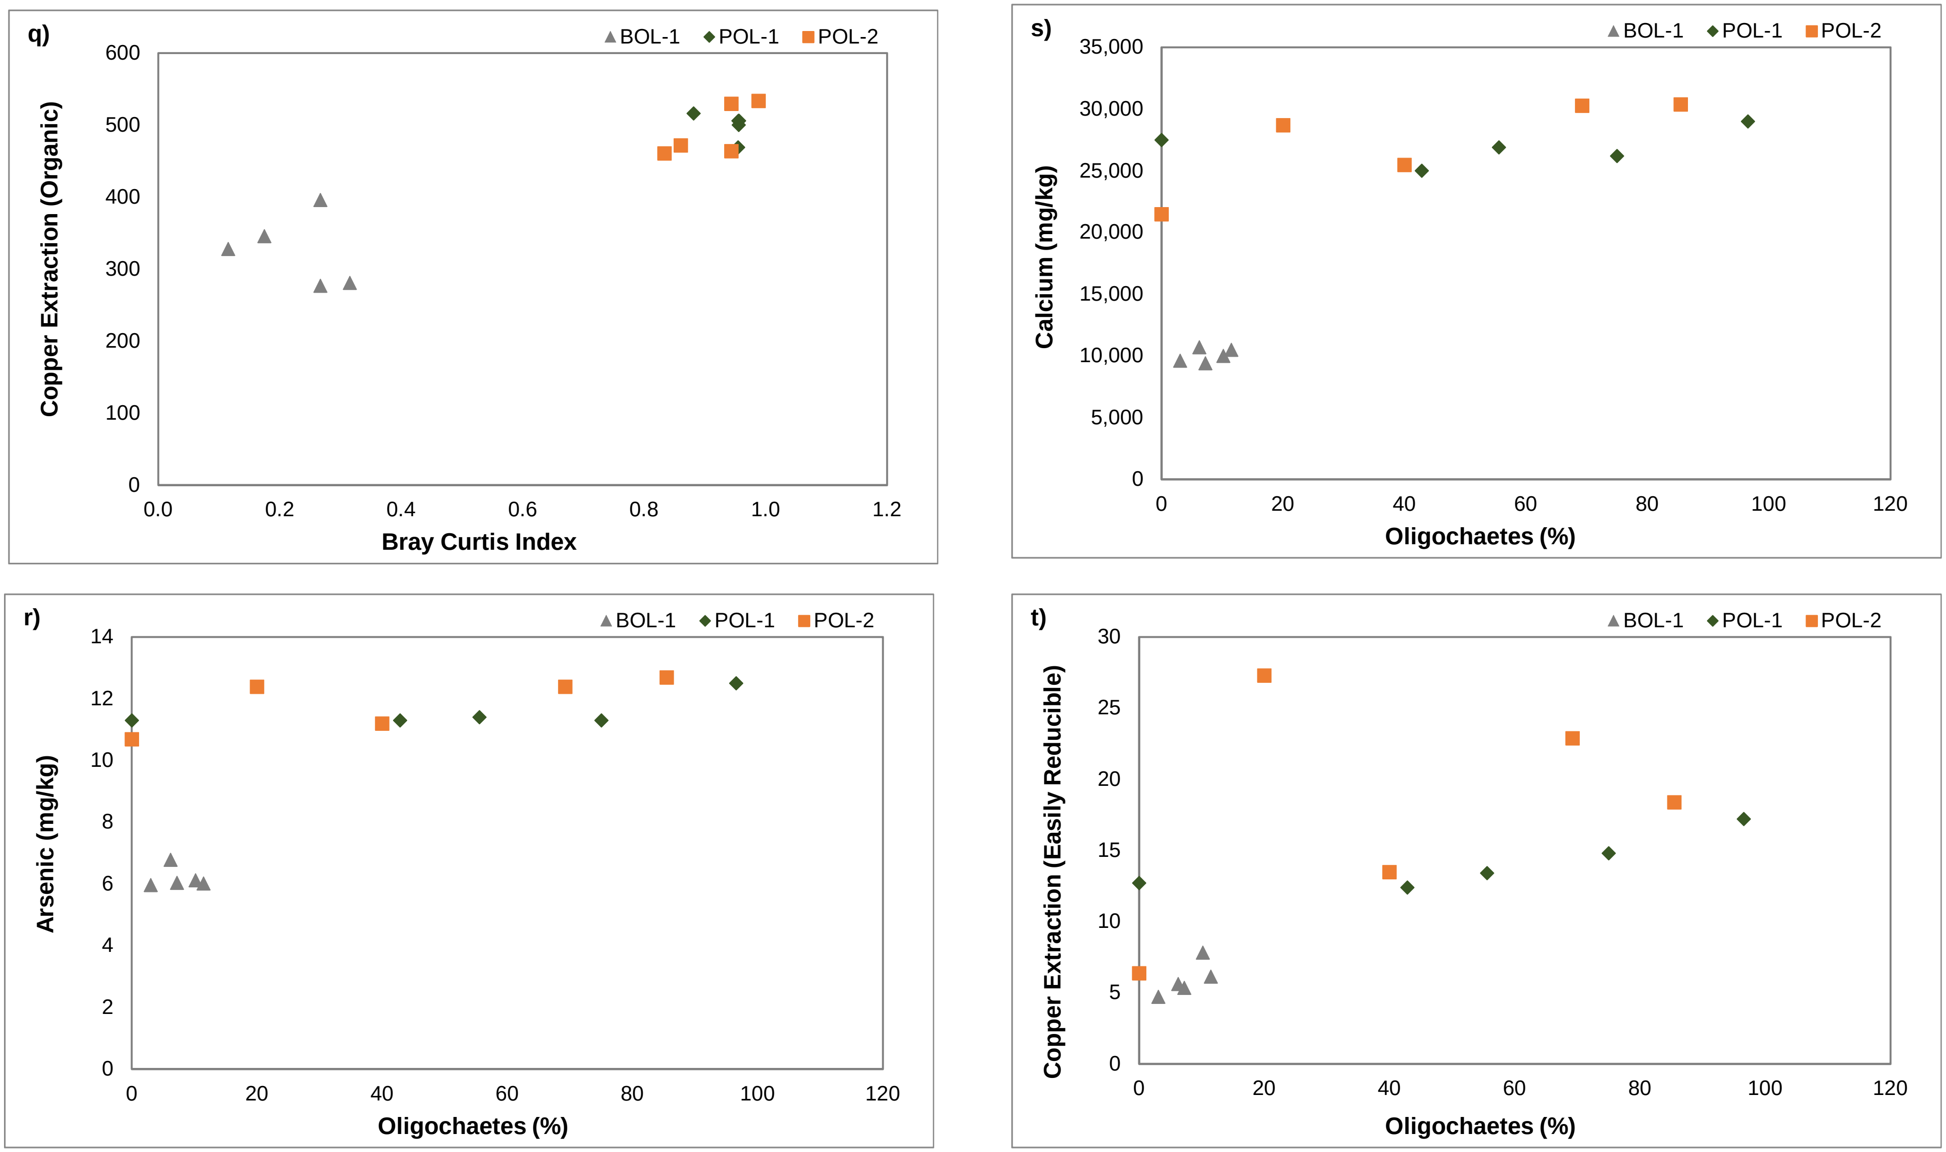

Figure I.4: Scatterplots of Spearman's correlation relationships (p<0.01) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake mid-depth sampling areas.

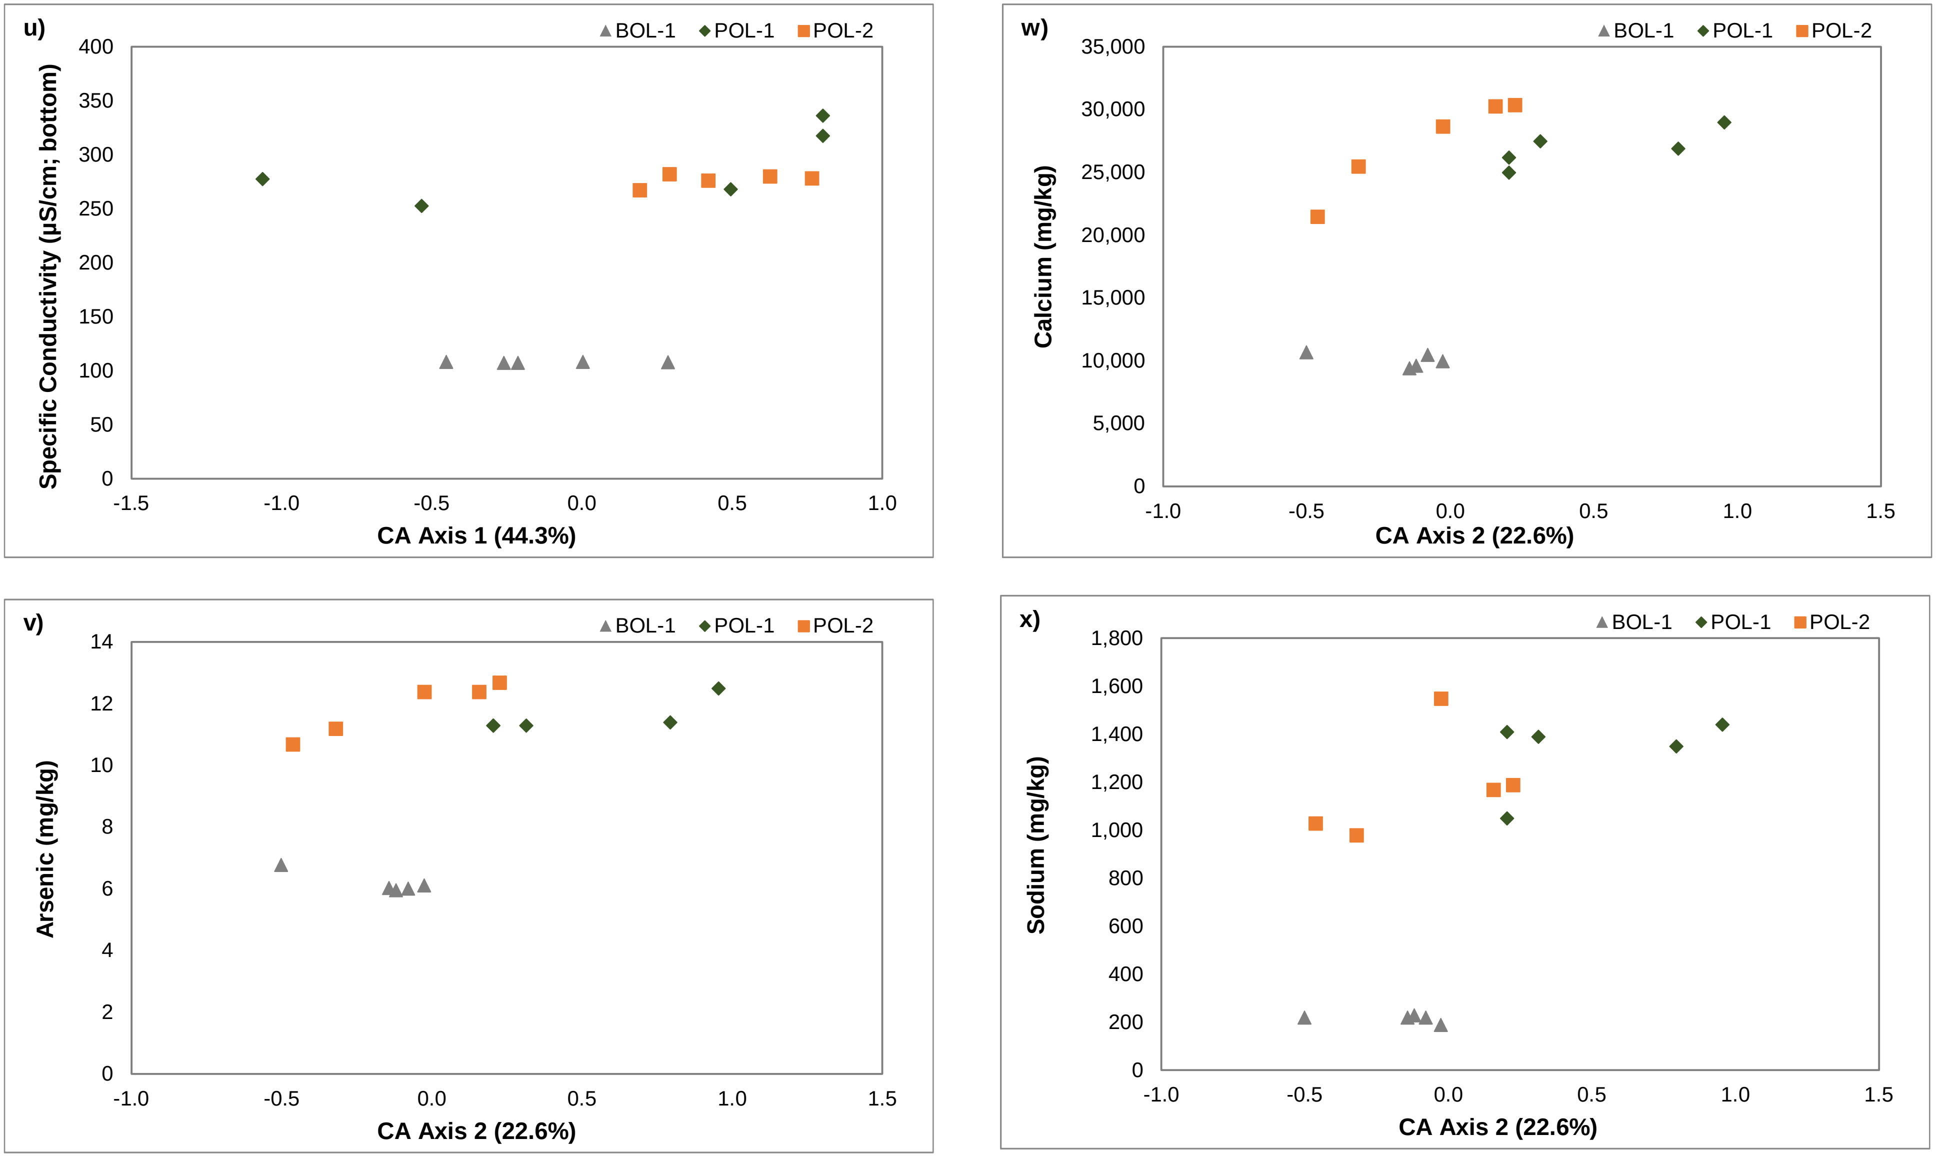

Figure I.4: Scatterplots of Spearman's correlation relationships ($p<0.01$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake mid-depth sampling areas.

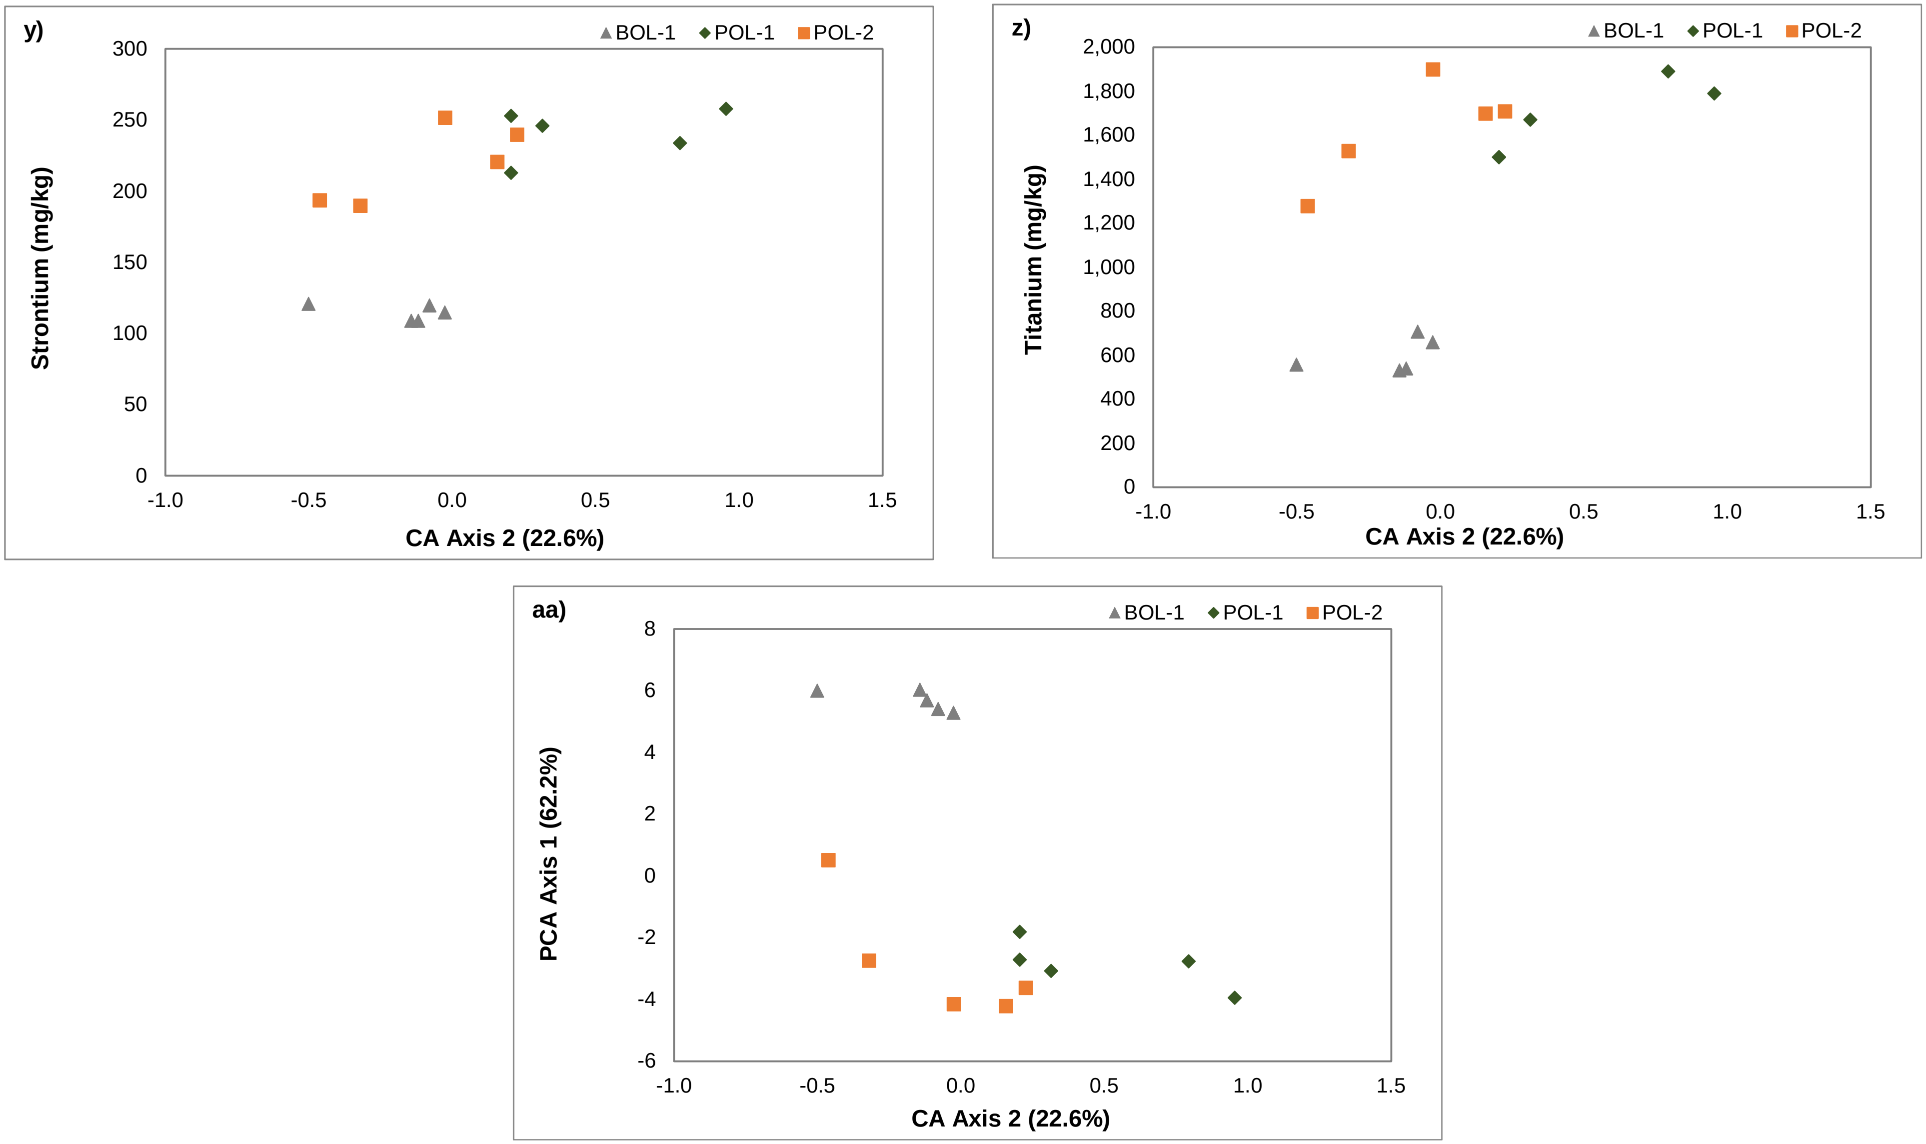

Figure I.4: Scatterplots of Spearman's correlation relationships (p<0.01) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake mid-depth sampling areas.

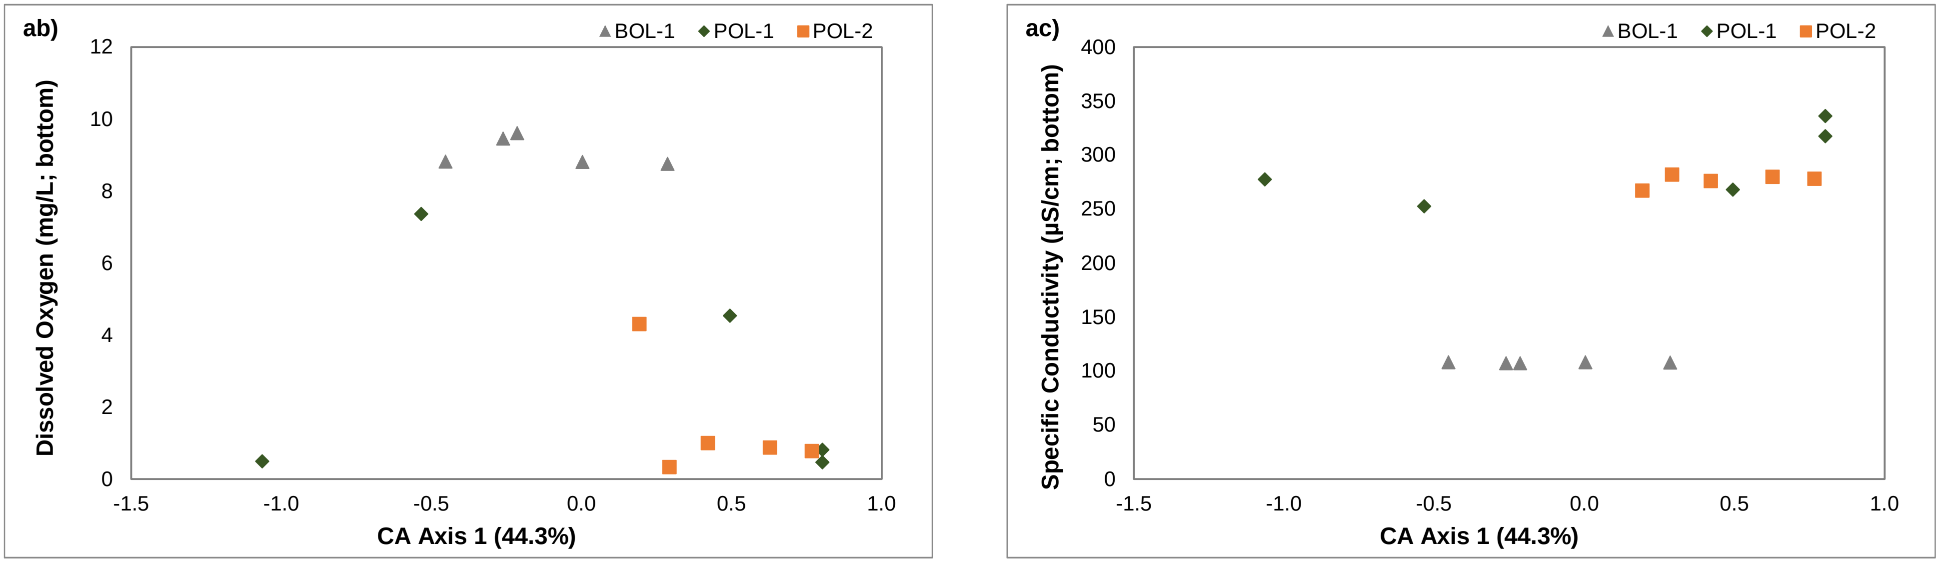

Figure I.4: Scatterplots of Spearman's correlation relationships (p<0.01) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake mid-depth sampling areas.

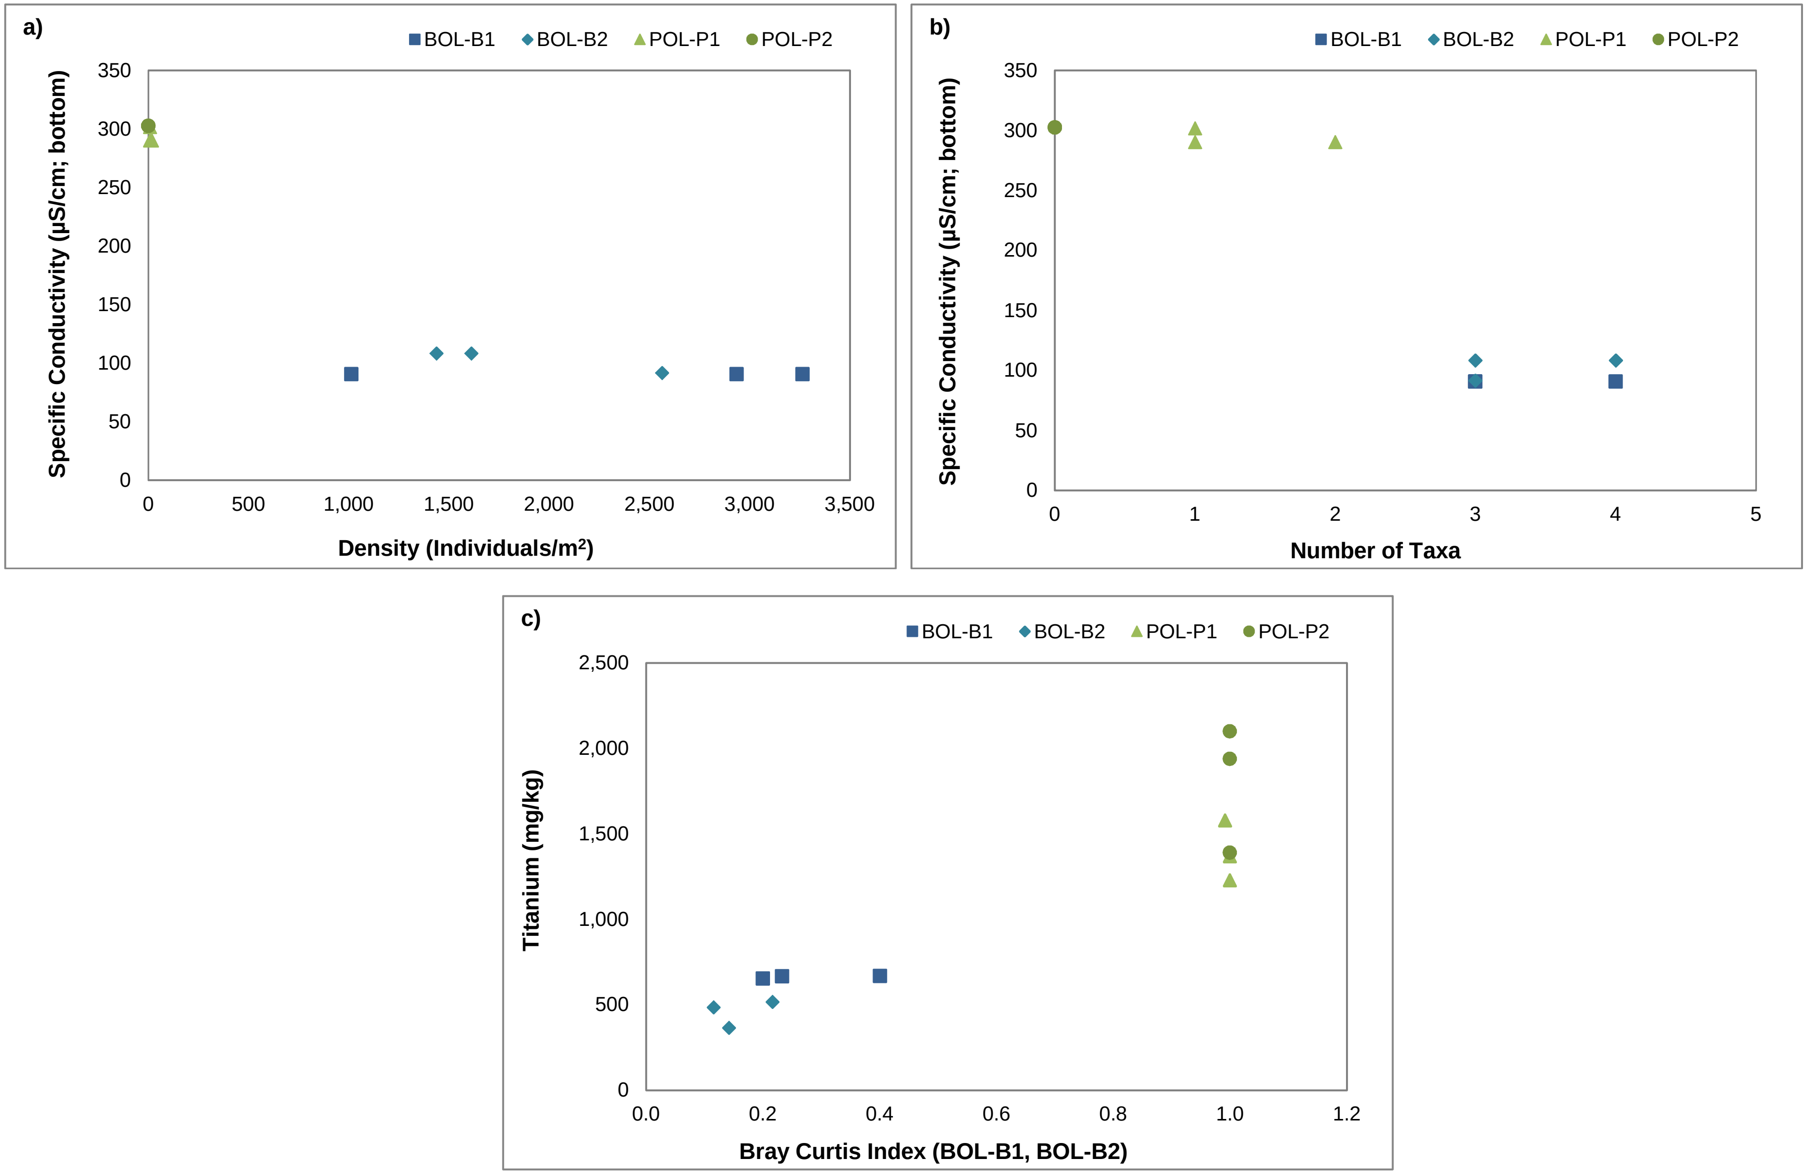

Figure I.5: Scatterplots of significant Spearman's correlation relationships ($p < 0.0001$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake deep sampling areas.

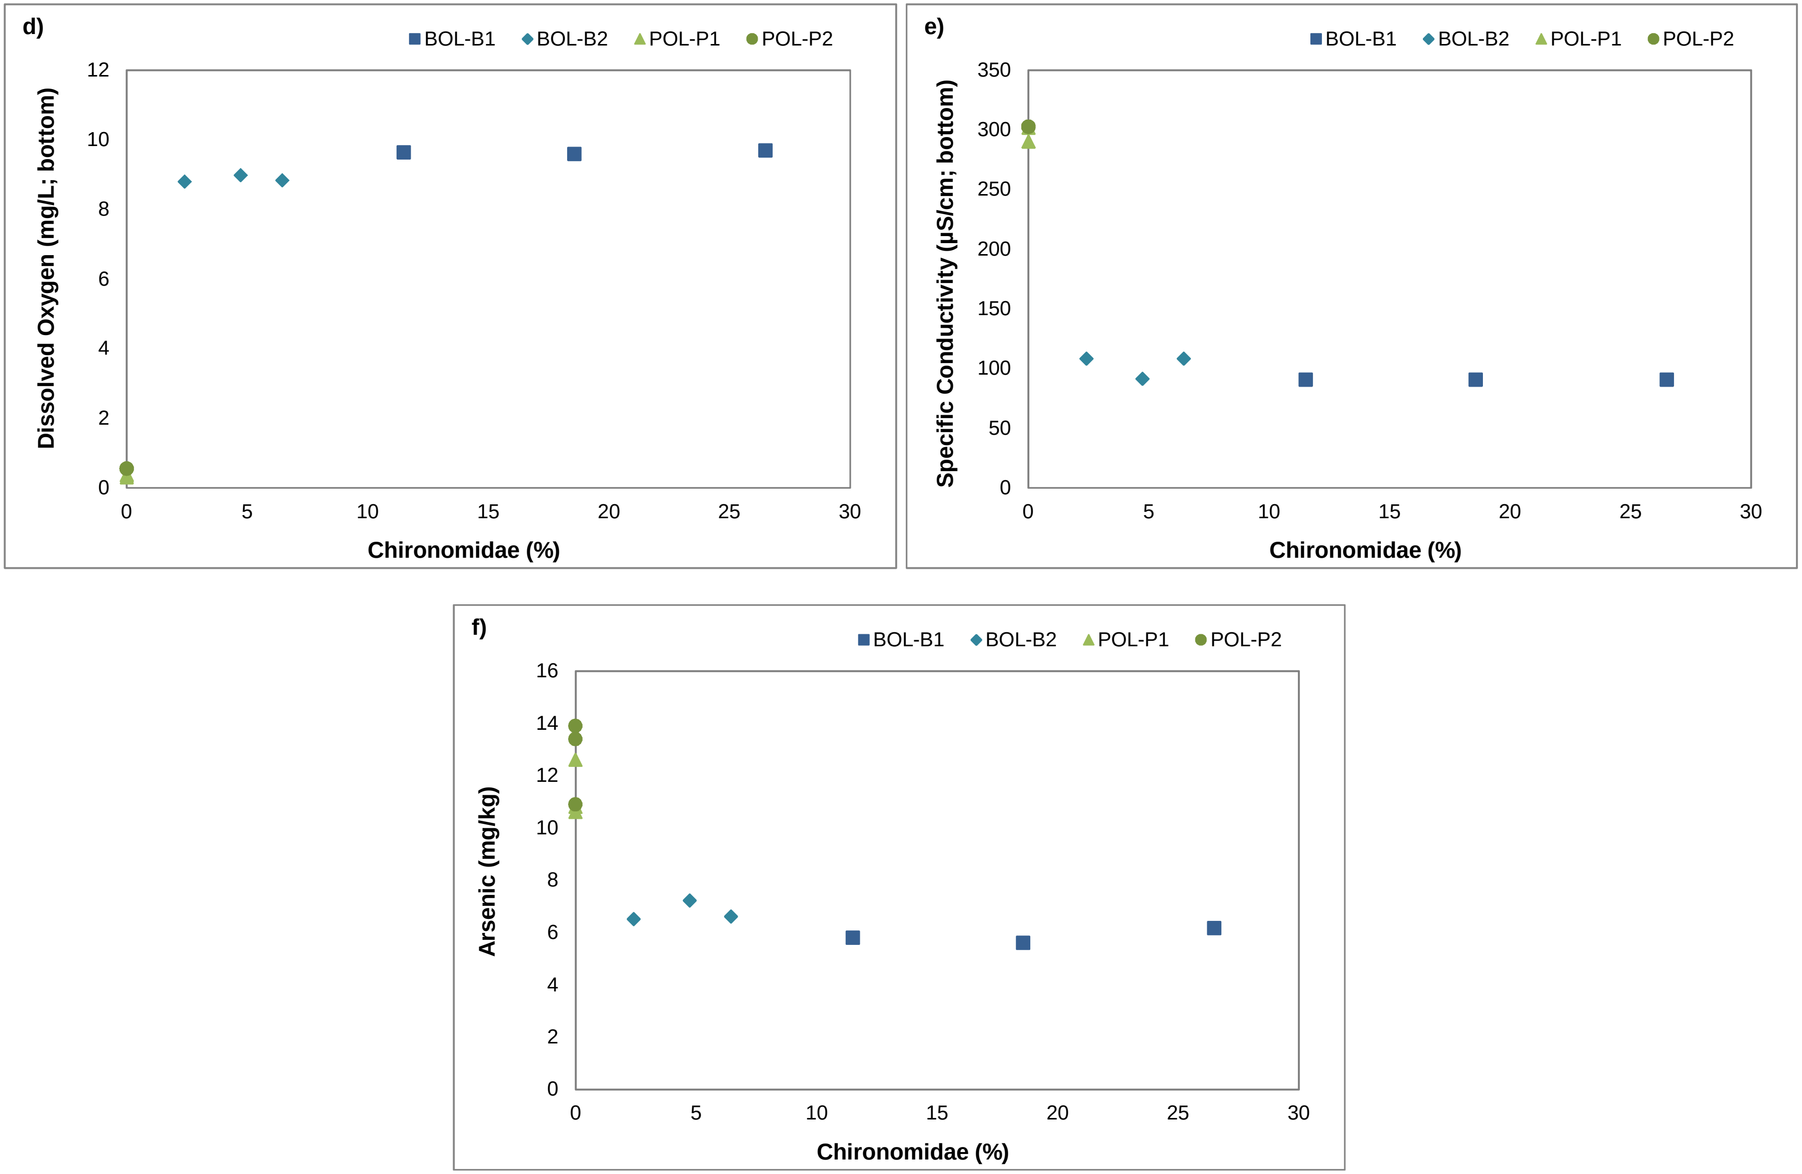

Figure I.5: Scatterplots of significant Spearman's correlation relationships ($p < 0.0001$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake deep sampling areas.

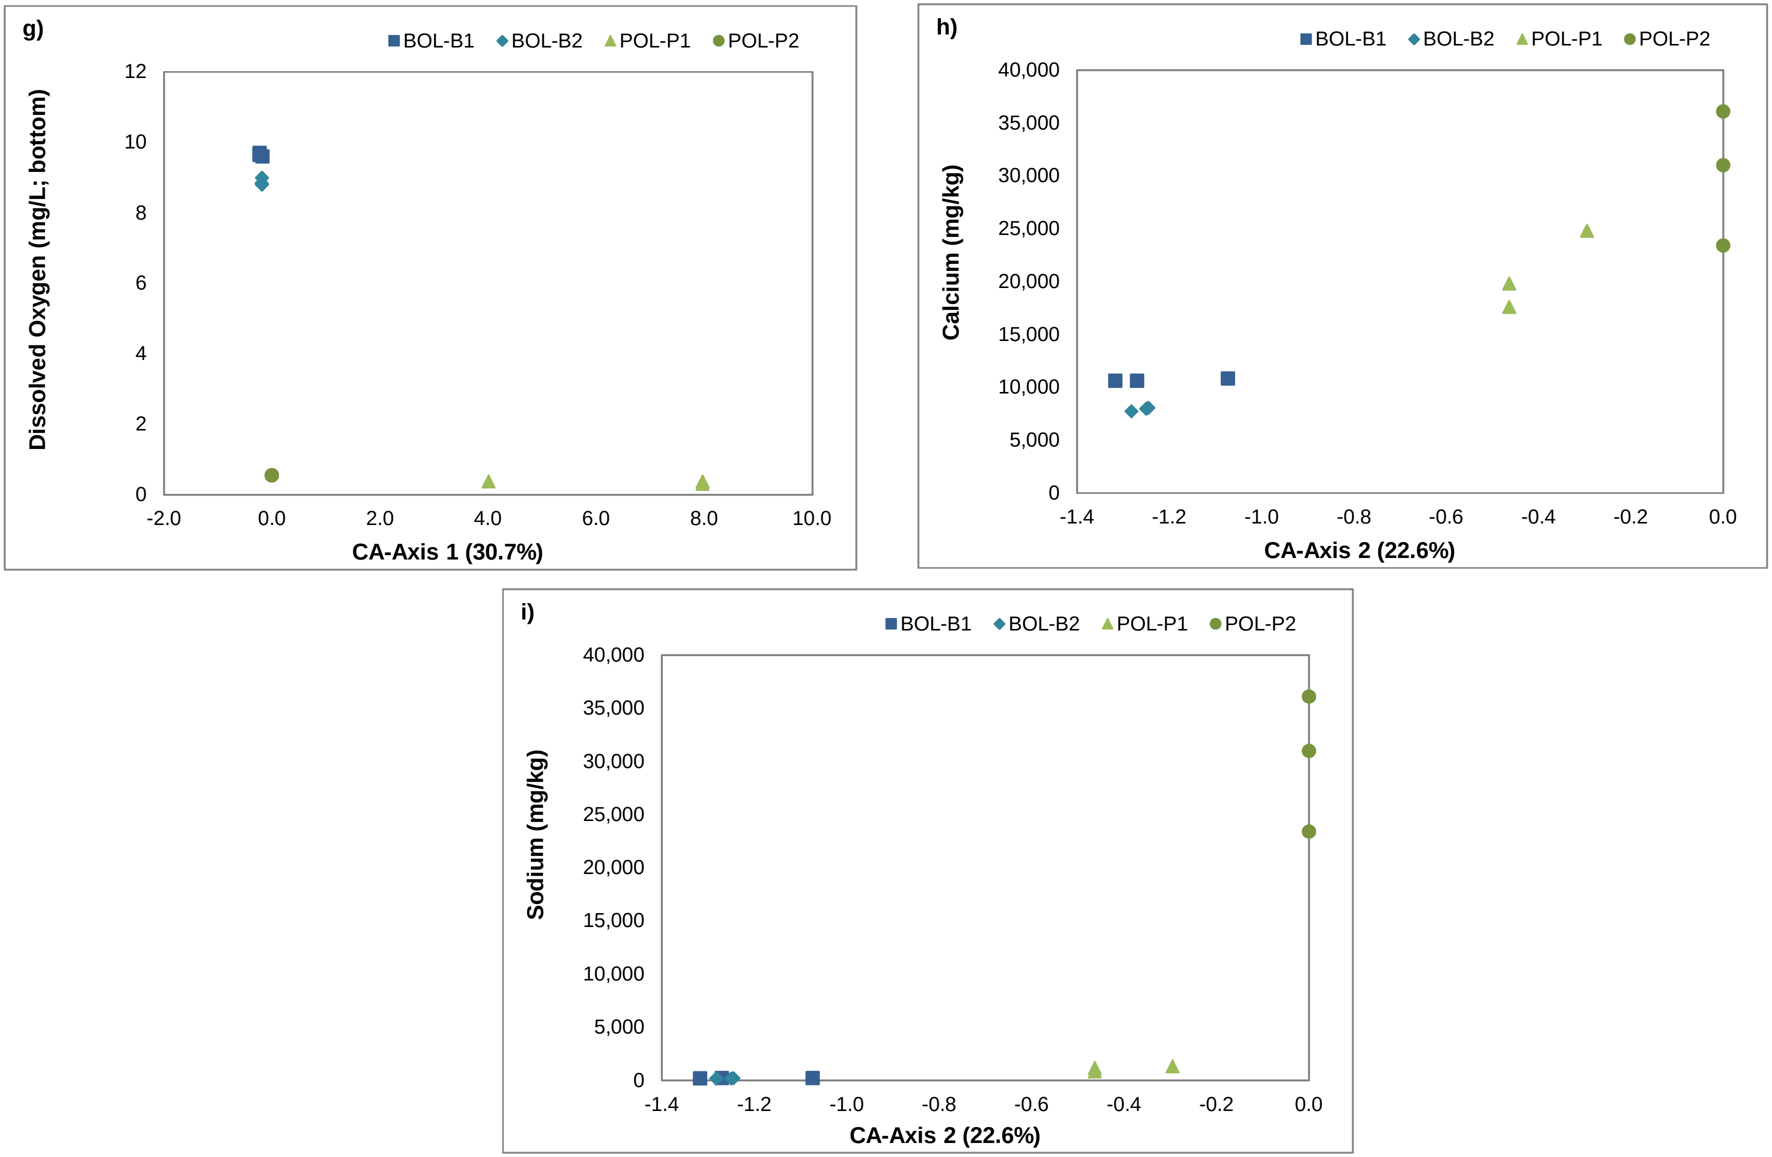

Figure I.5: Scatterplots of significant Spearman's correlation relationships ($p < 0.0001$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake deep sampling areas.

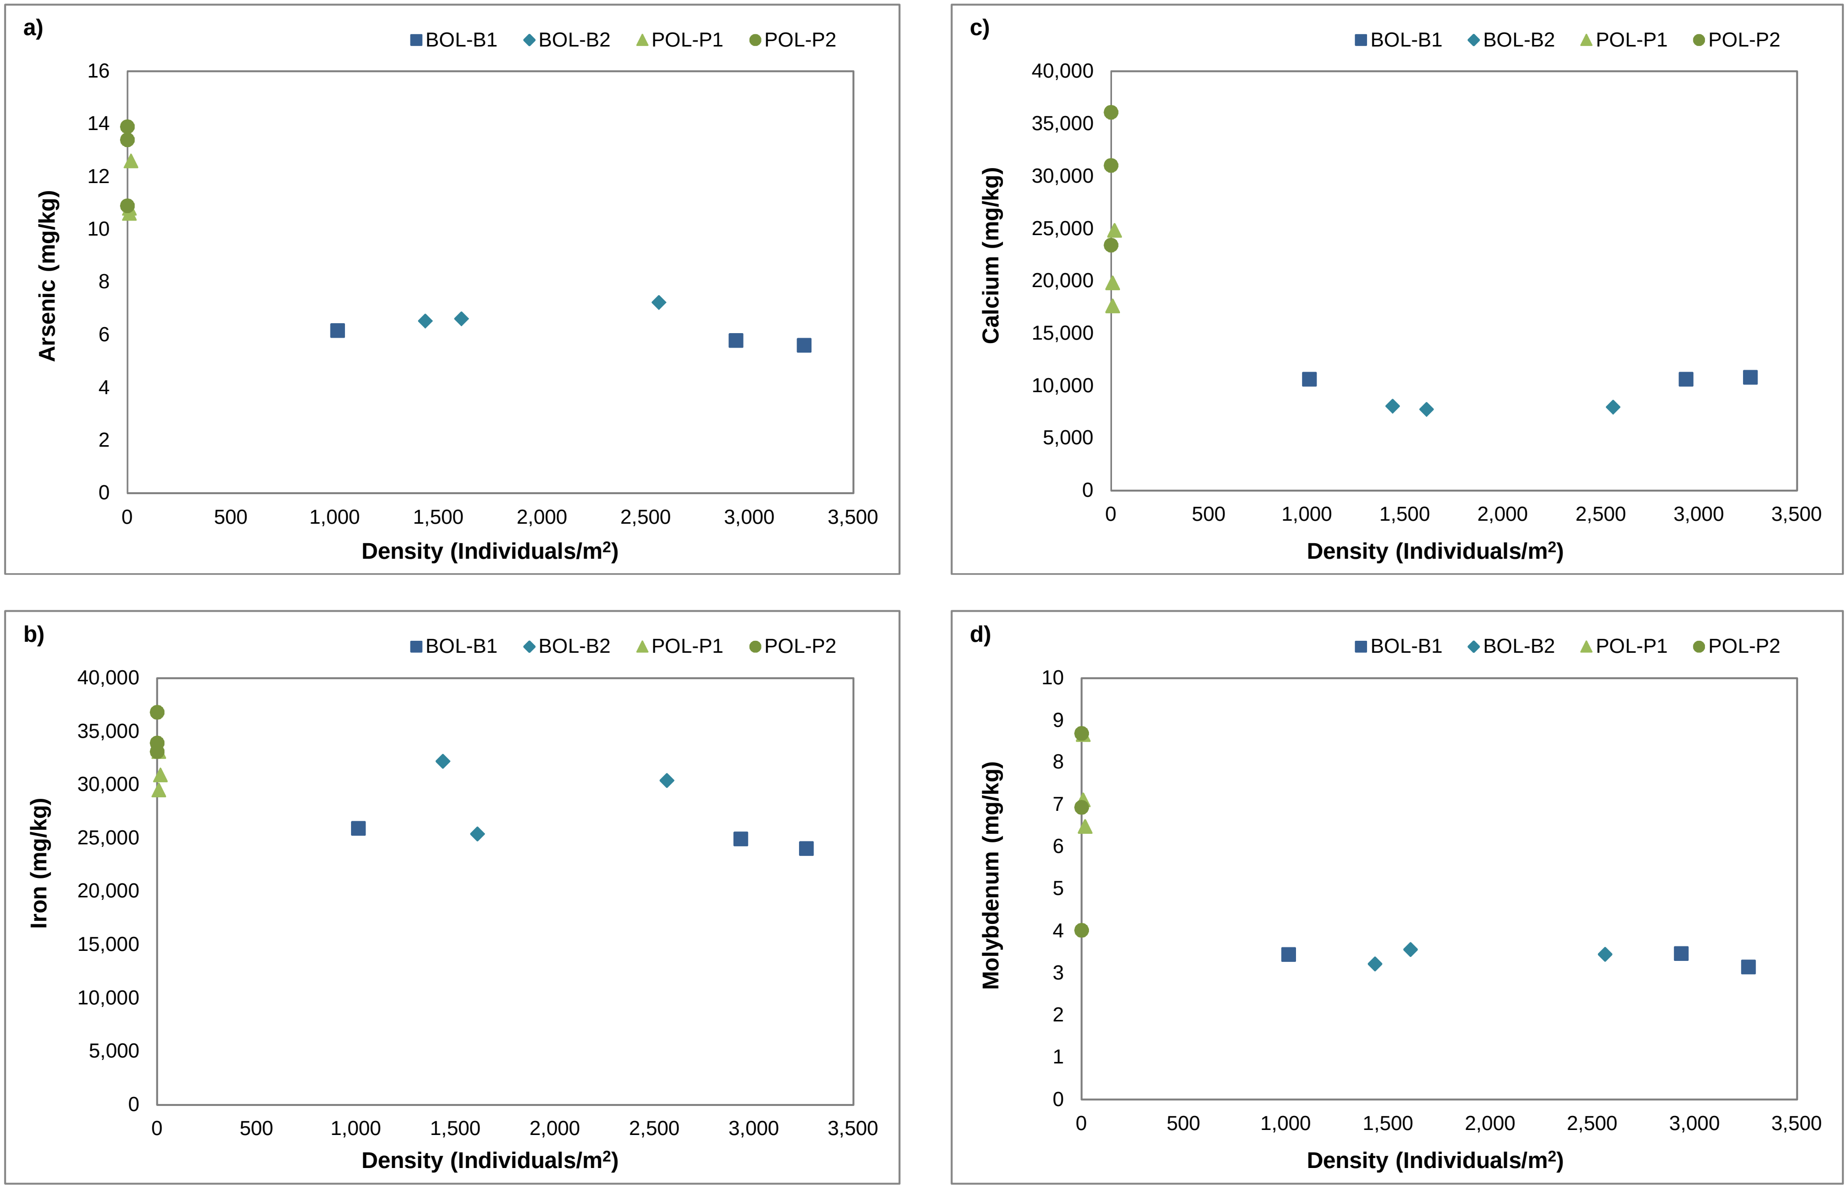

Figure I.6: Scatterplots of Spearman's correlation relationships ($p < 0.01$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake deep sampling areas.

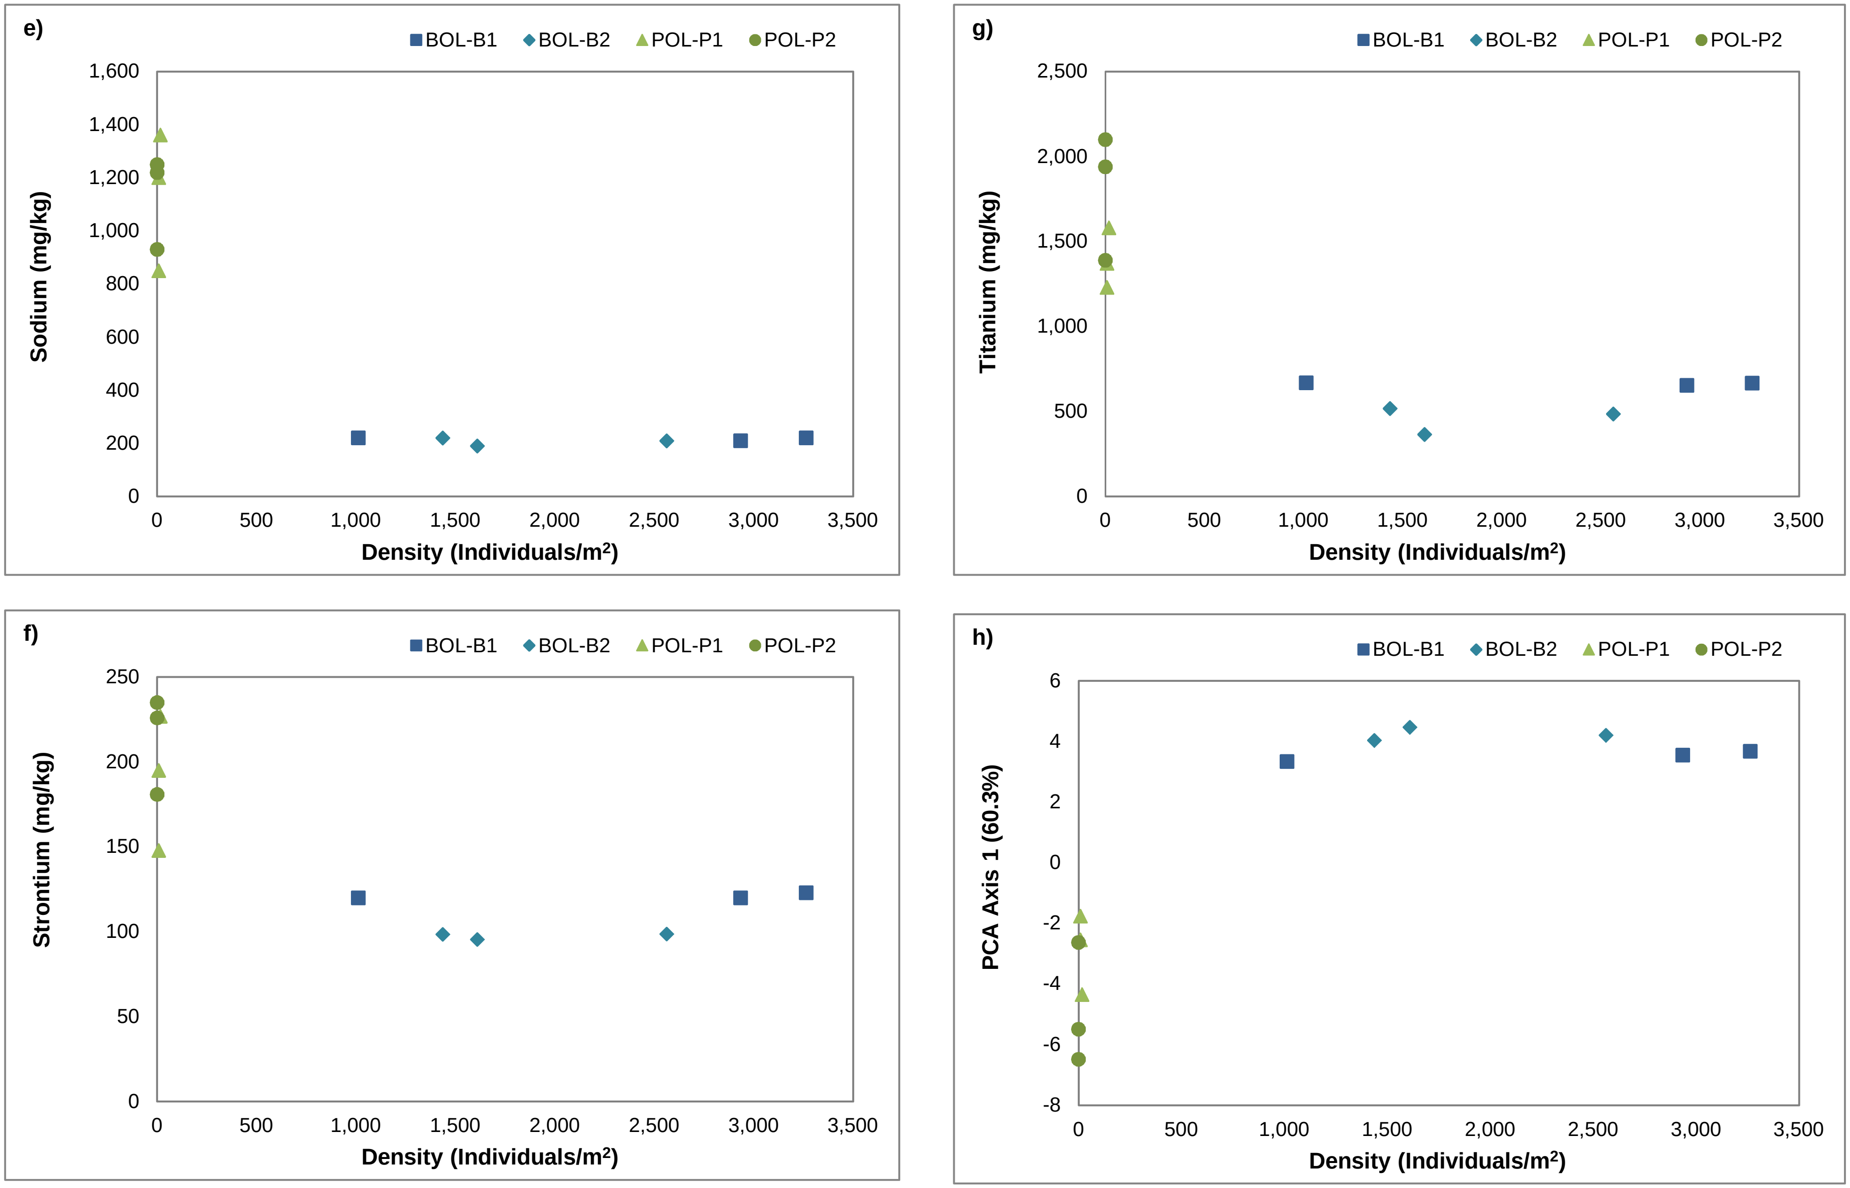

Figure I.6: Scatterplots of Spearman's correlation relationships ($p < 0.01$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake deep sampling areas.

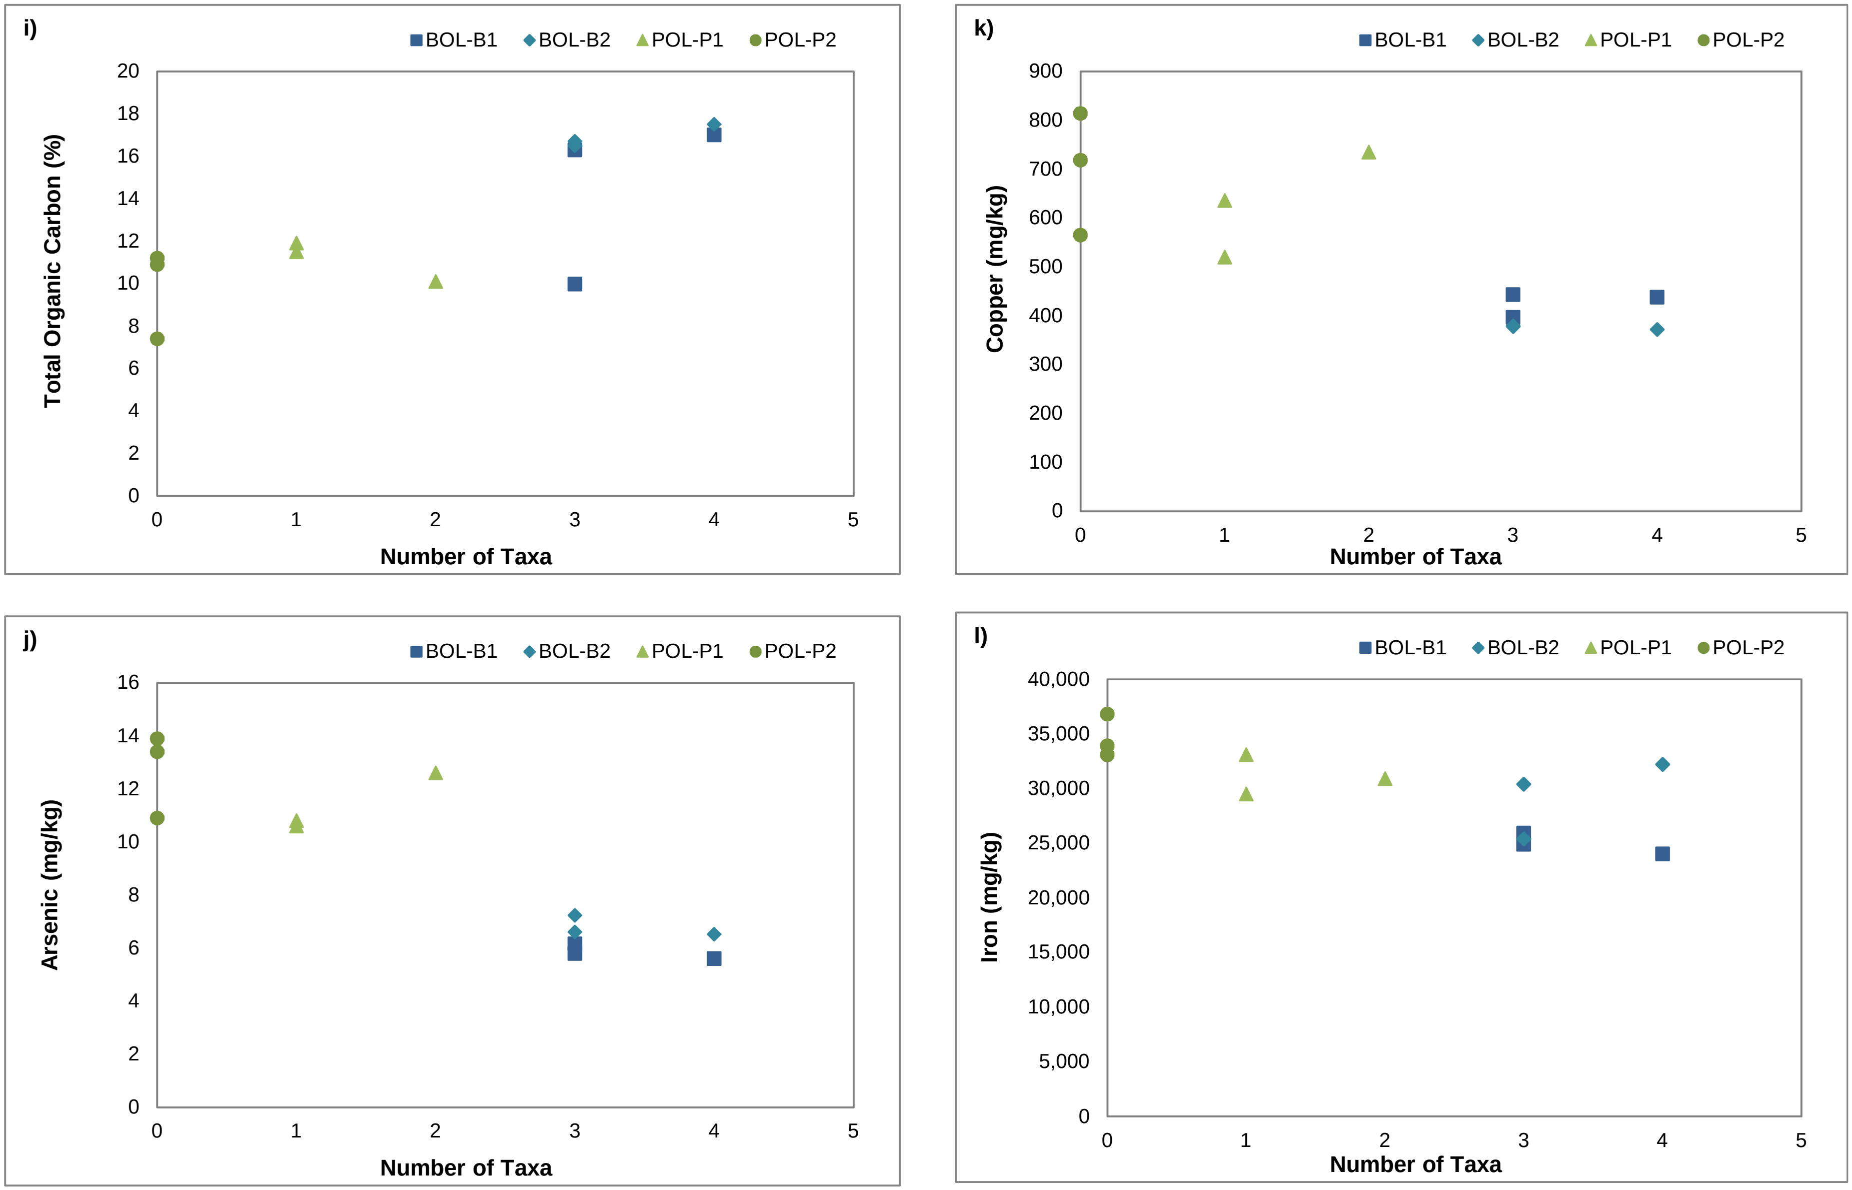

Figure I.6: Scatterplots of Spearman's correlation relationships (p < 0.01) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake deep sampling areas.

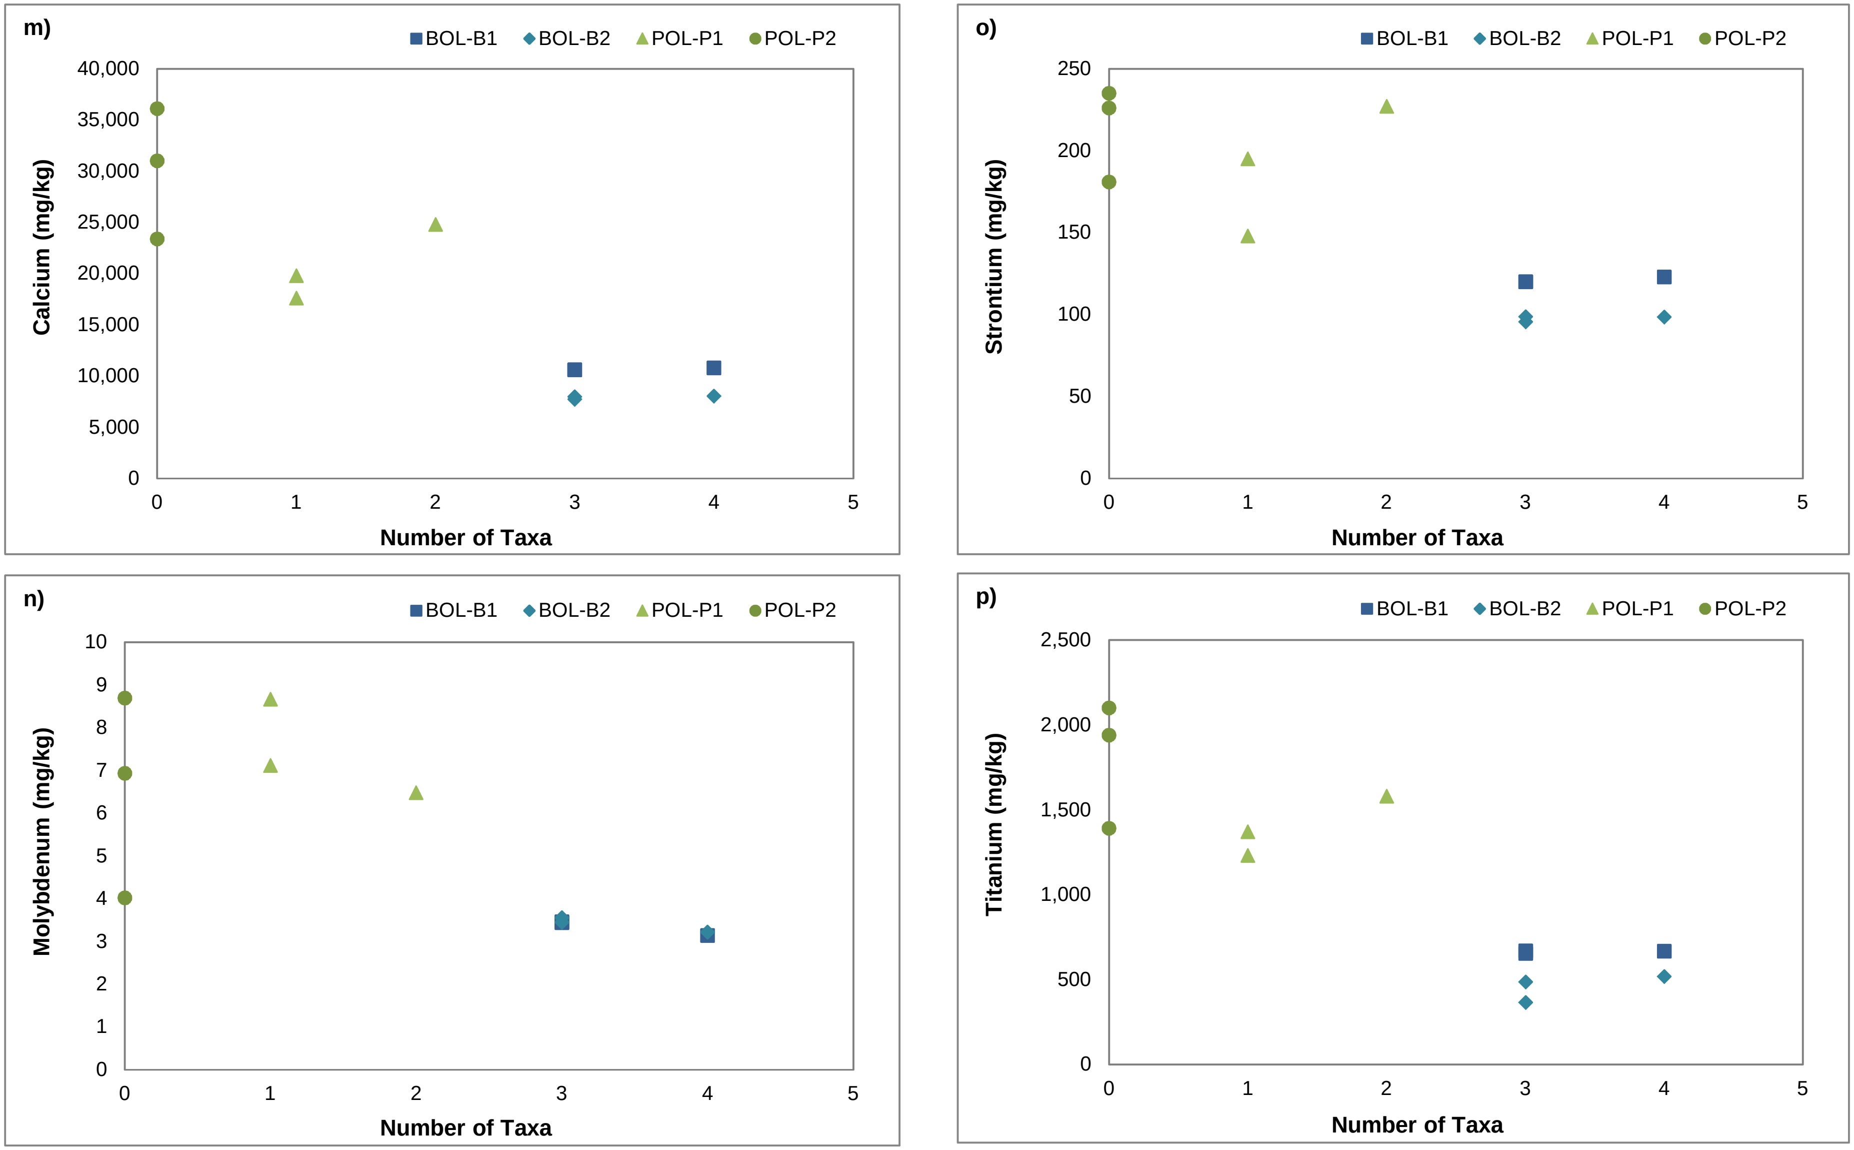

Figure I.6: Scatterplots of Spearman's correlation relationships ($p < 0.01$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake deep sampling areas.

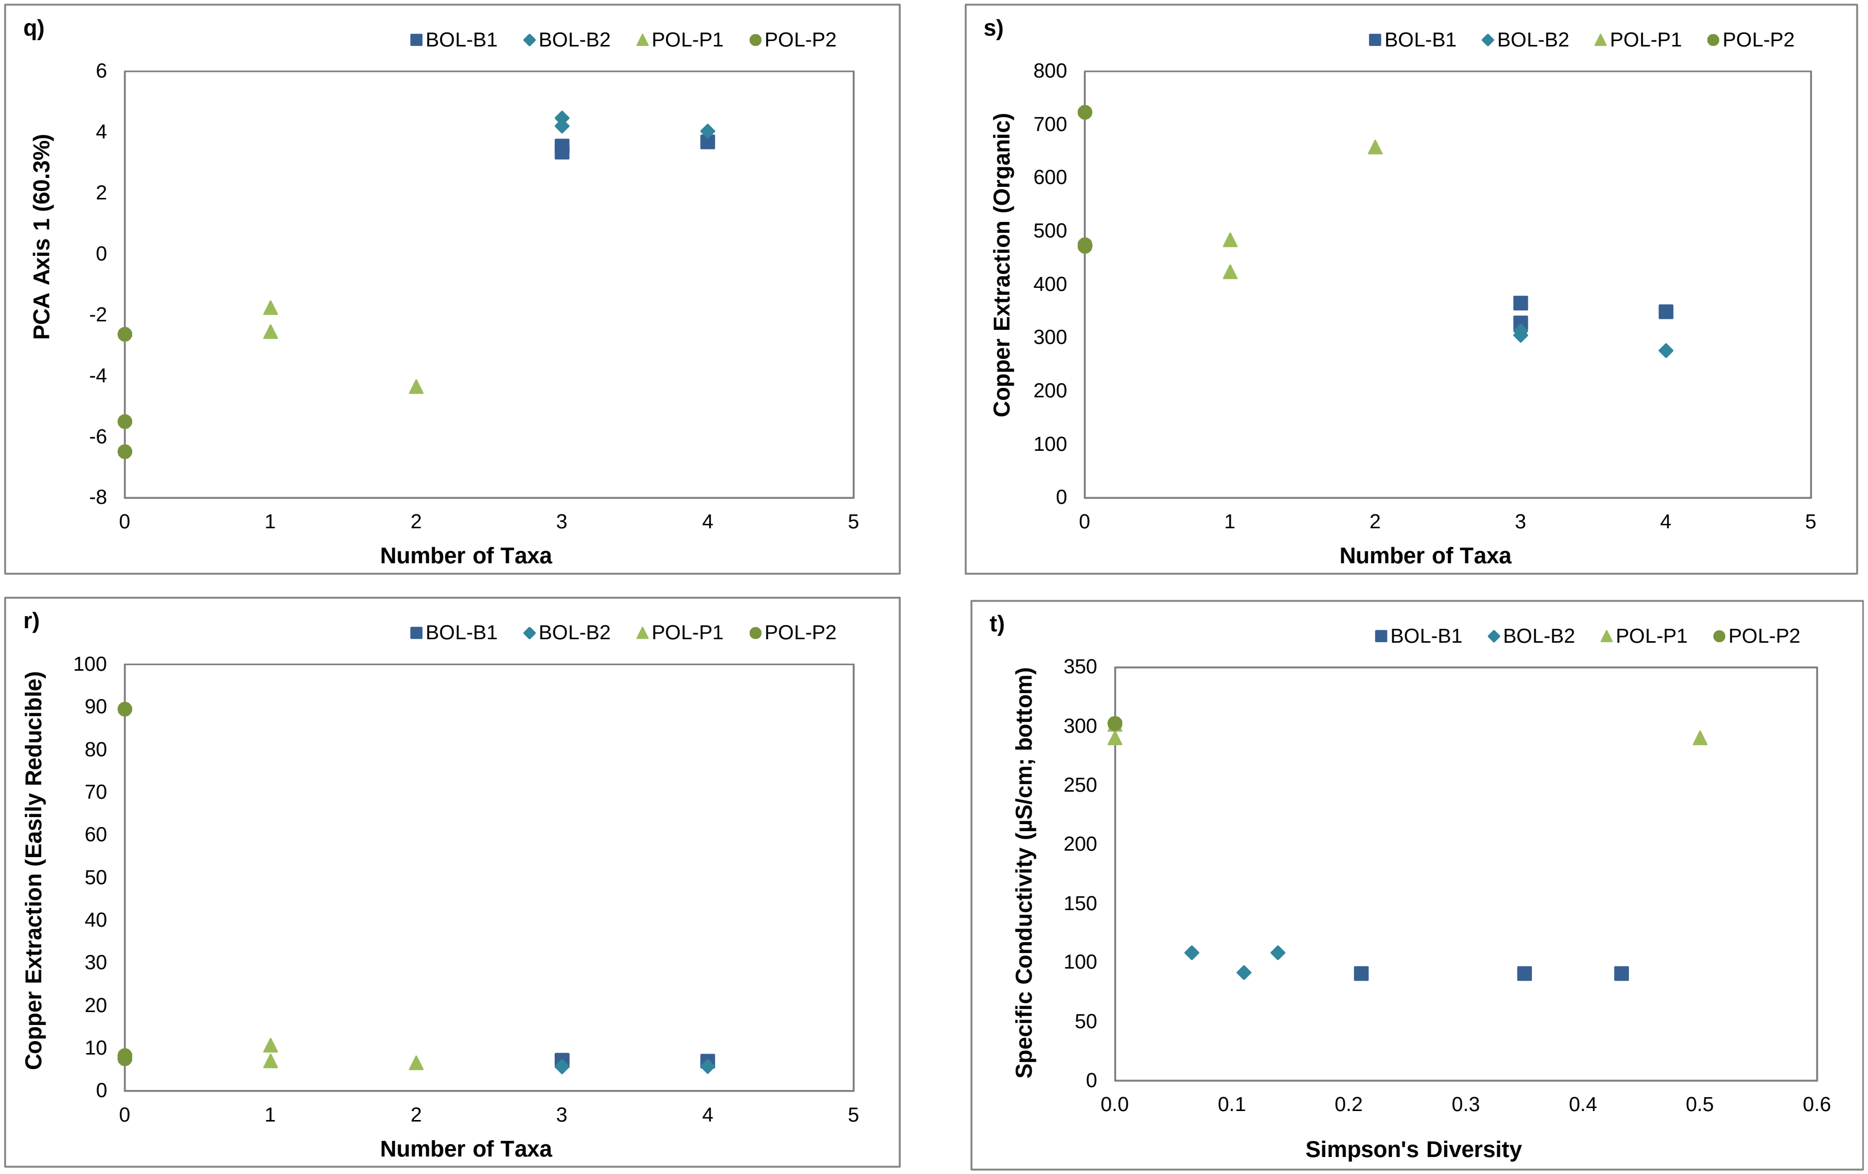

Figure I.6: Scatterplots of Spearman's correlation relationships ($p < 0.01$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake deep sampling areas.

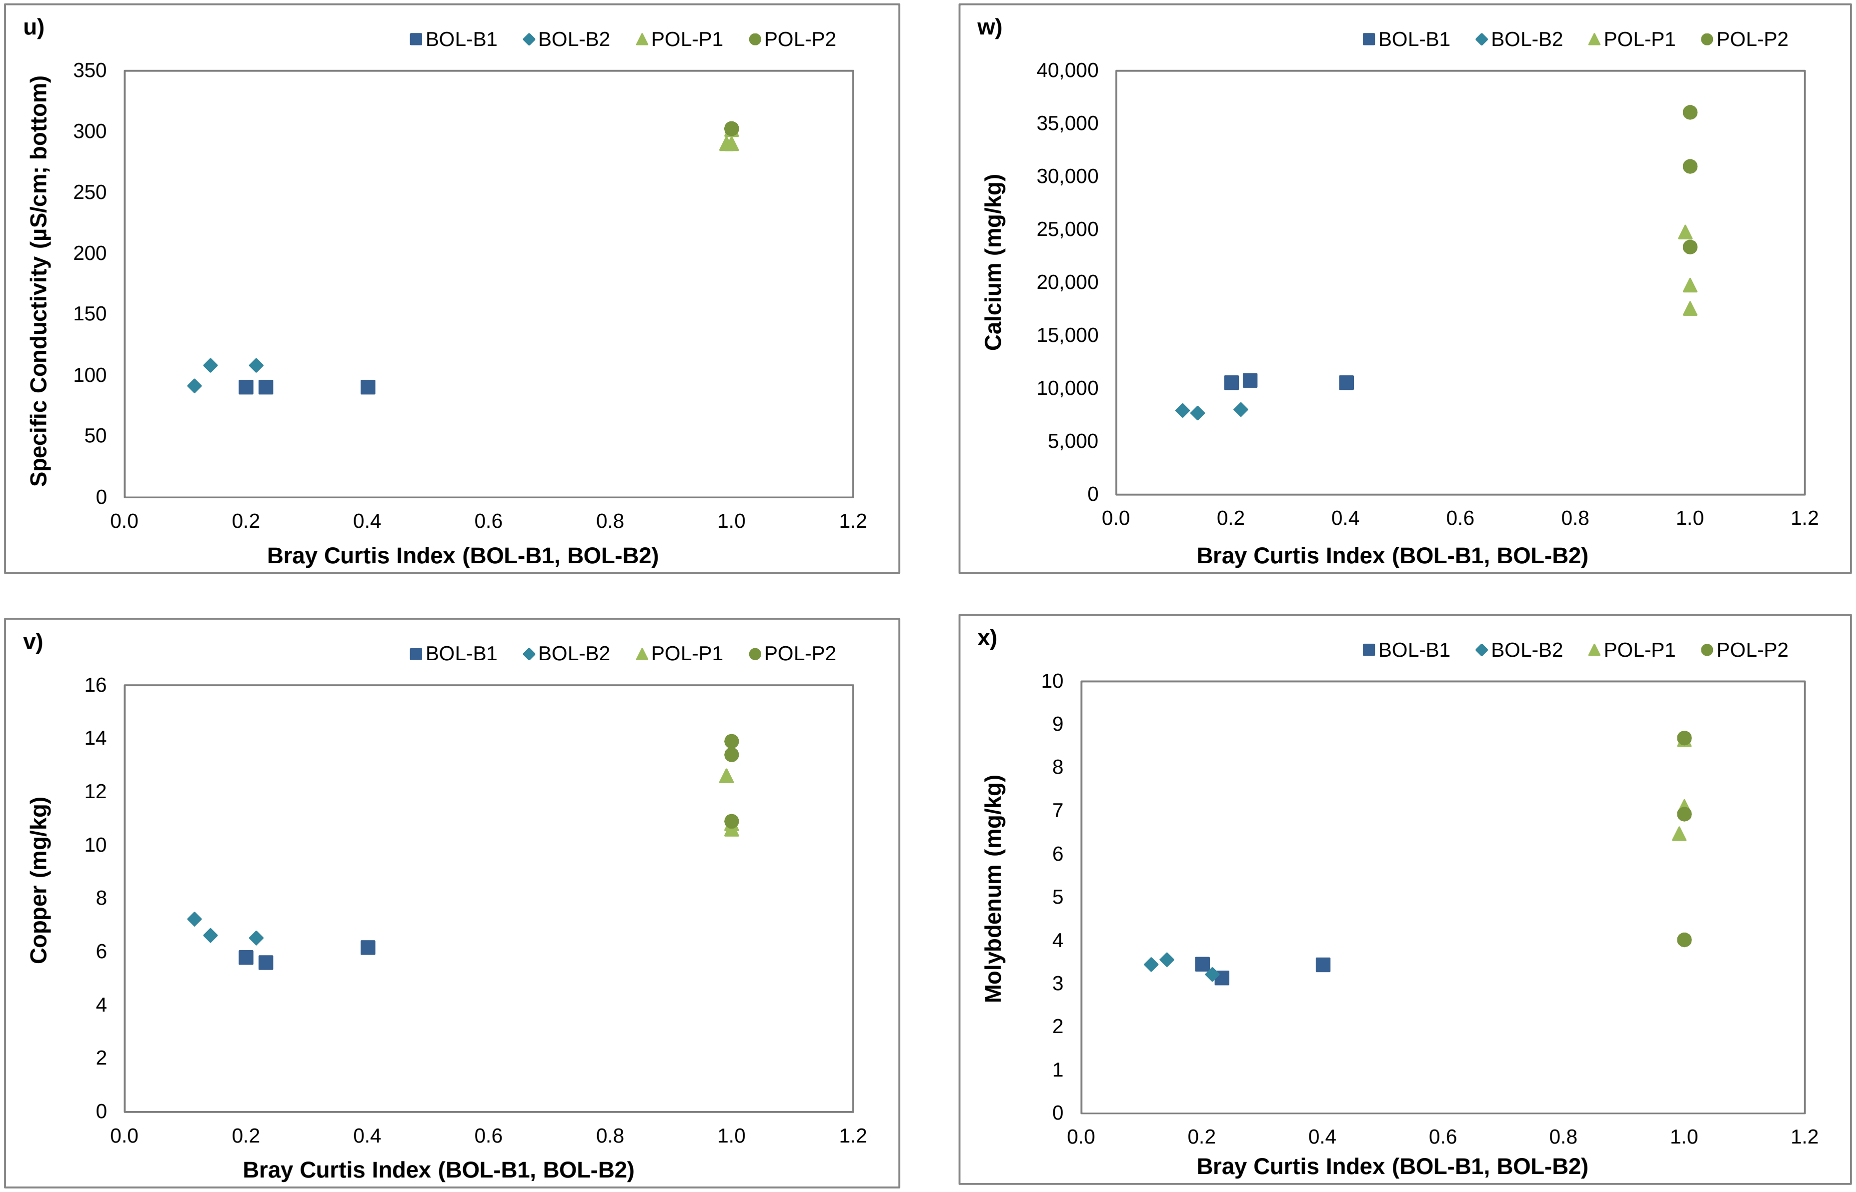

Figure I.6: Scatterplots of Spearman's correlation relationships (p < 0.01) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake deep sampling areas.

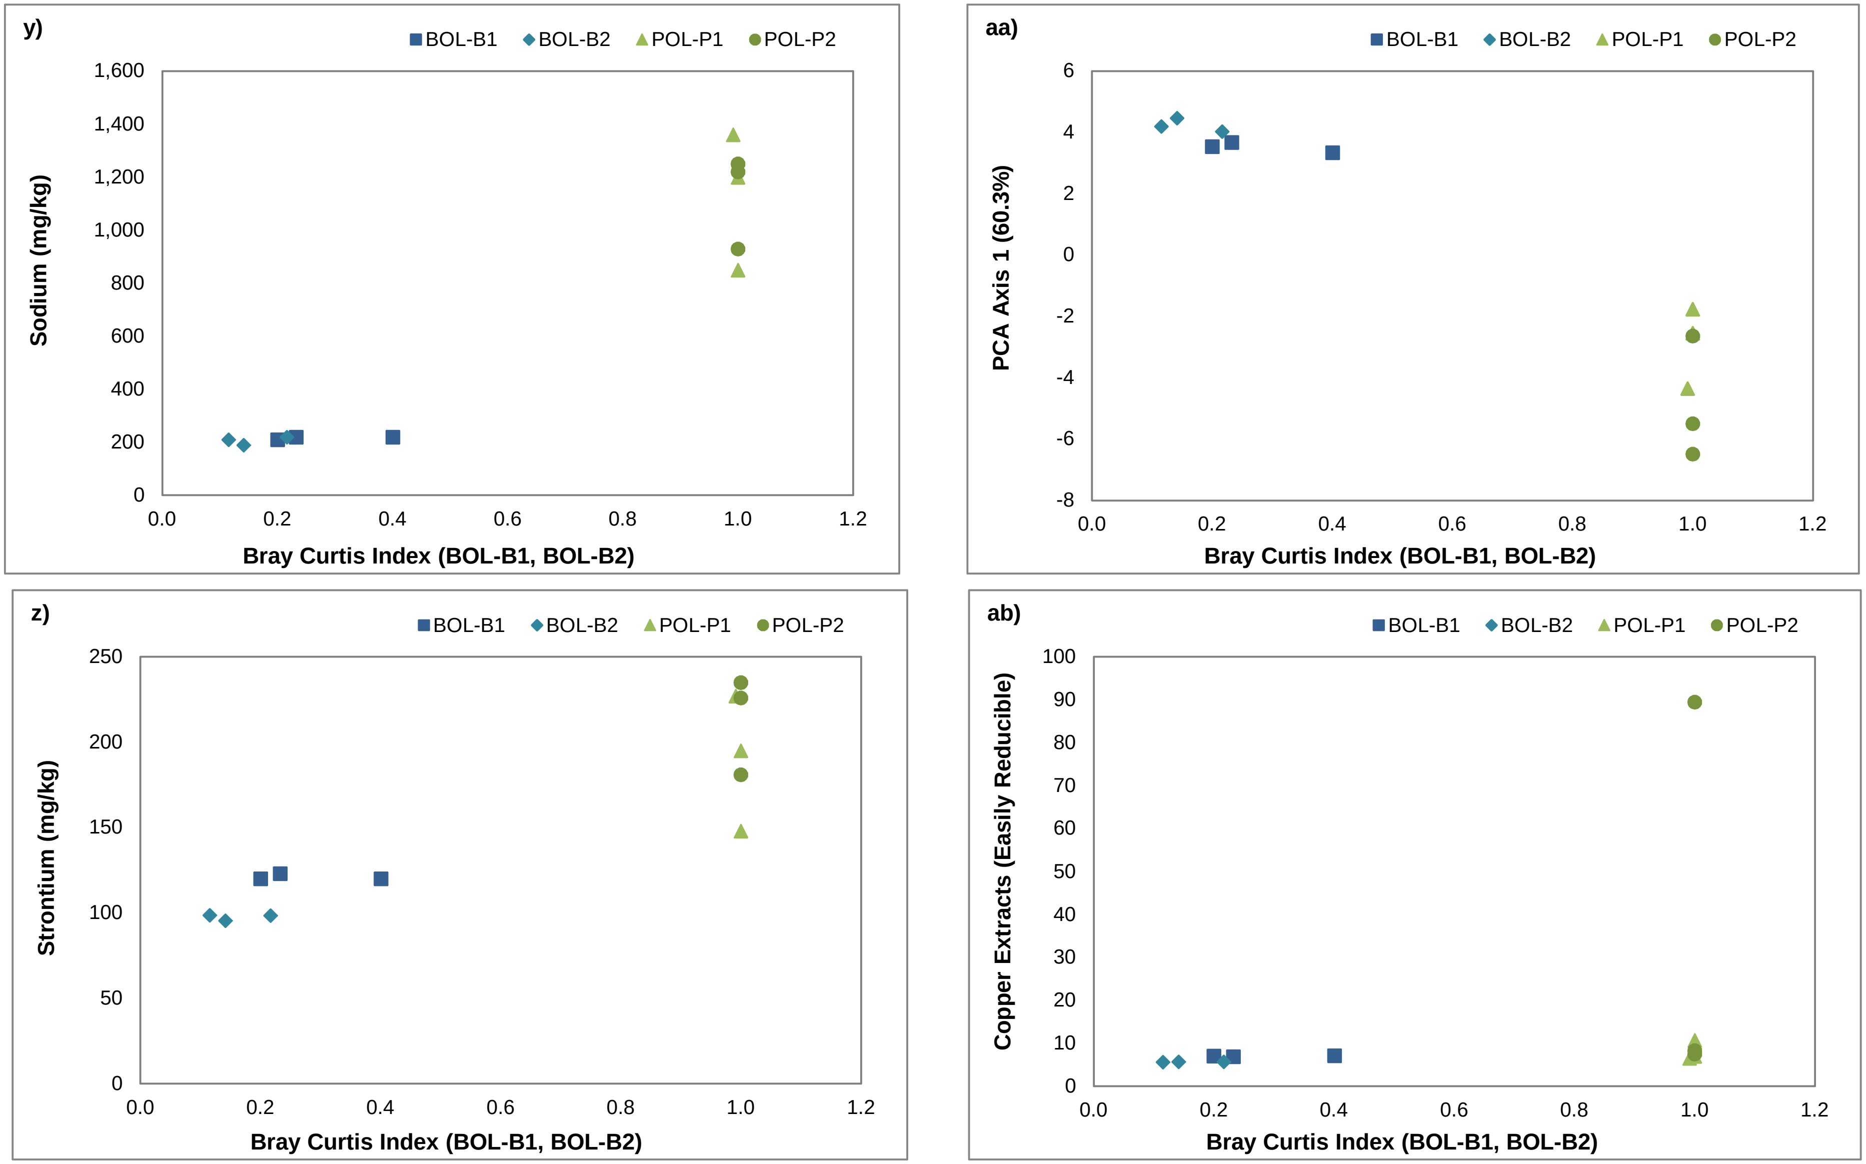

Figure I.6: Scatterplots of Spearman's correlation relationships ($p < 0.01$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake deep sampling areas.

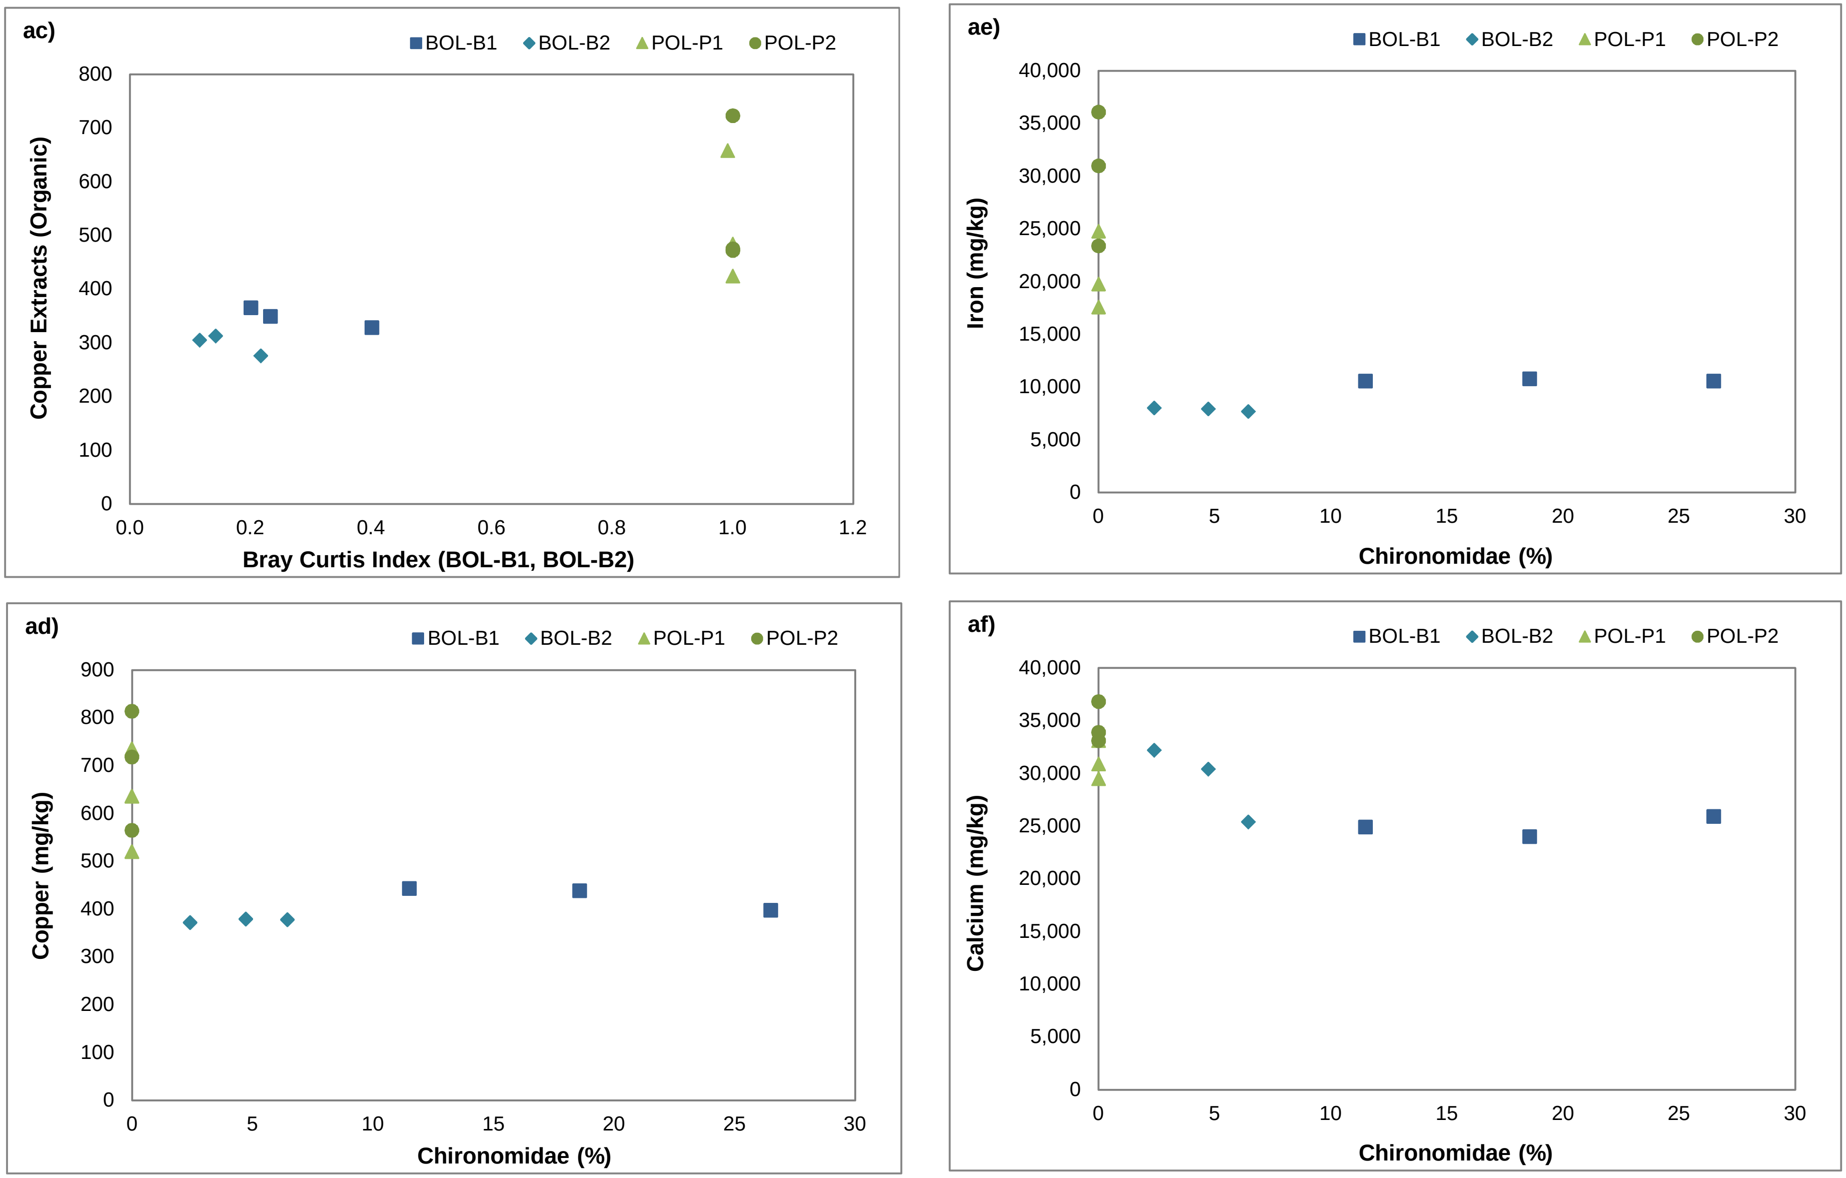

Figure I.6: Scatterplots of Spearman's correlation relationships (p < 0.01) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake deep sampling areas.

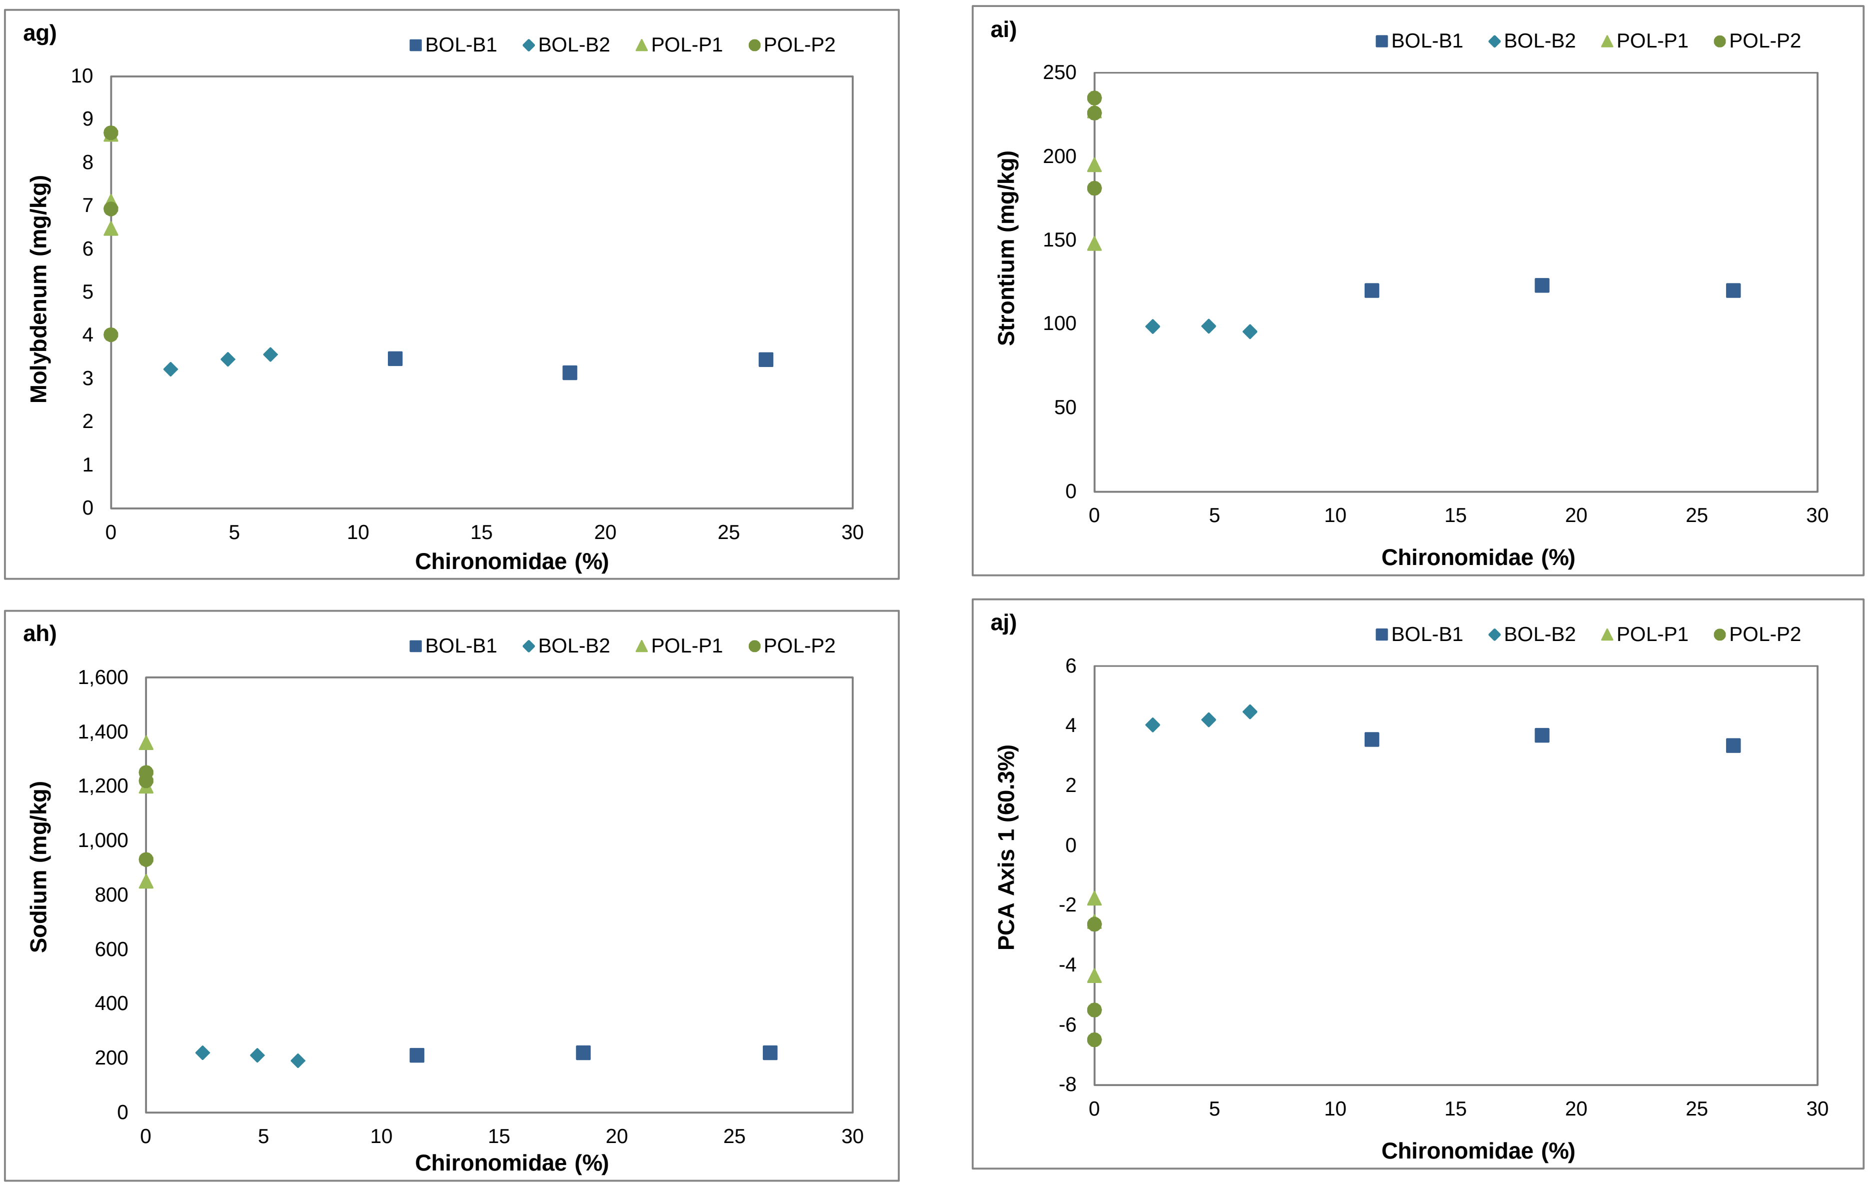

Figure I.6: Scatterplots of Spearman's correlation relationships ($p < 0.01$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake deep sampling areas.

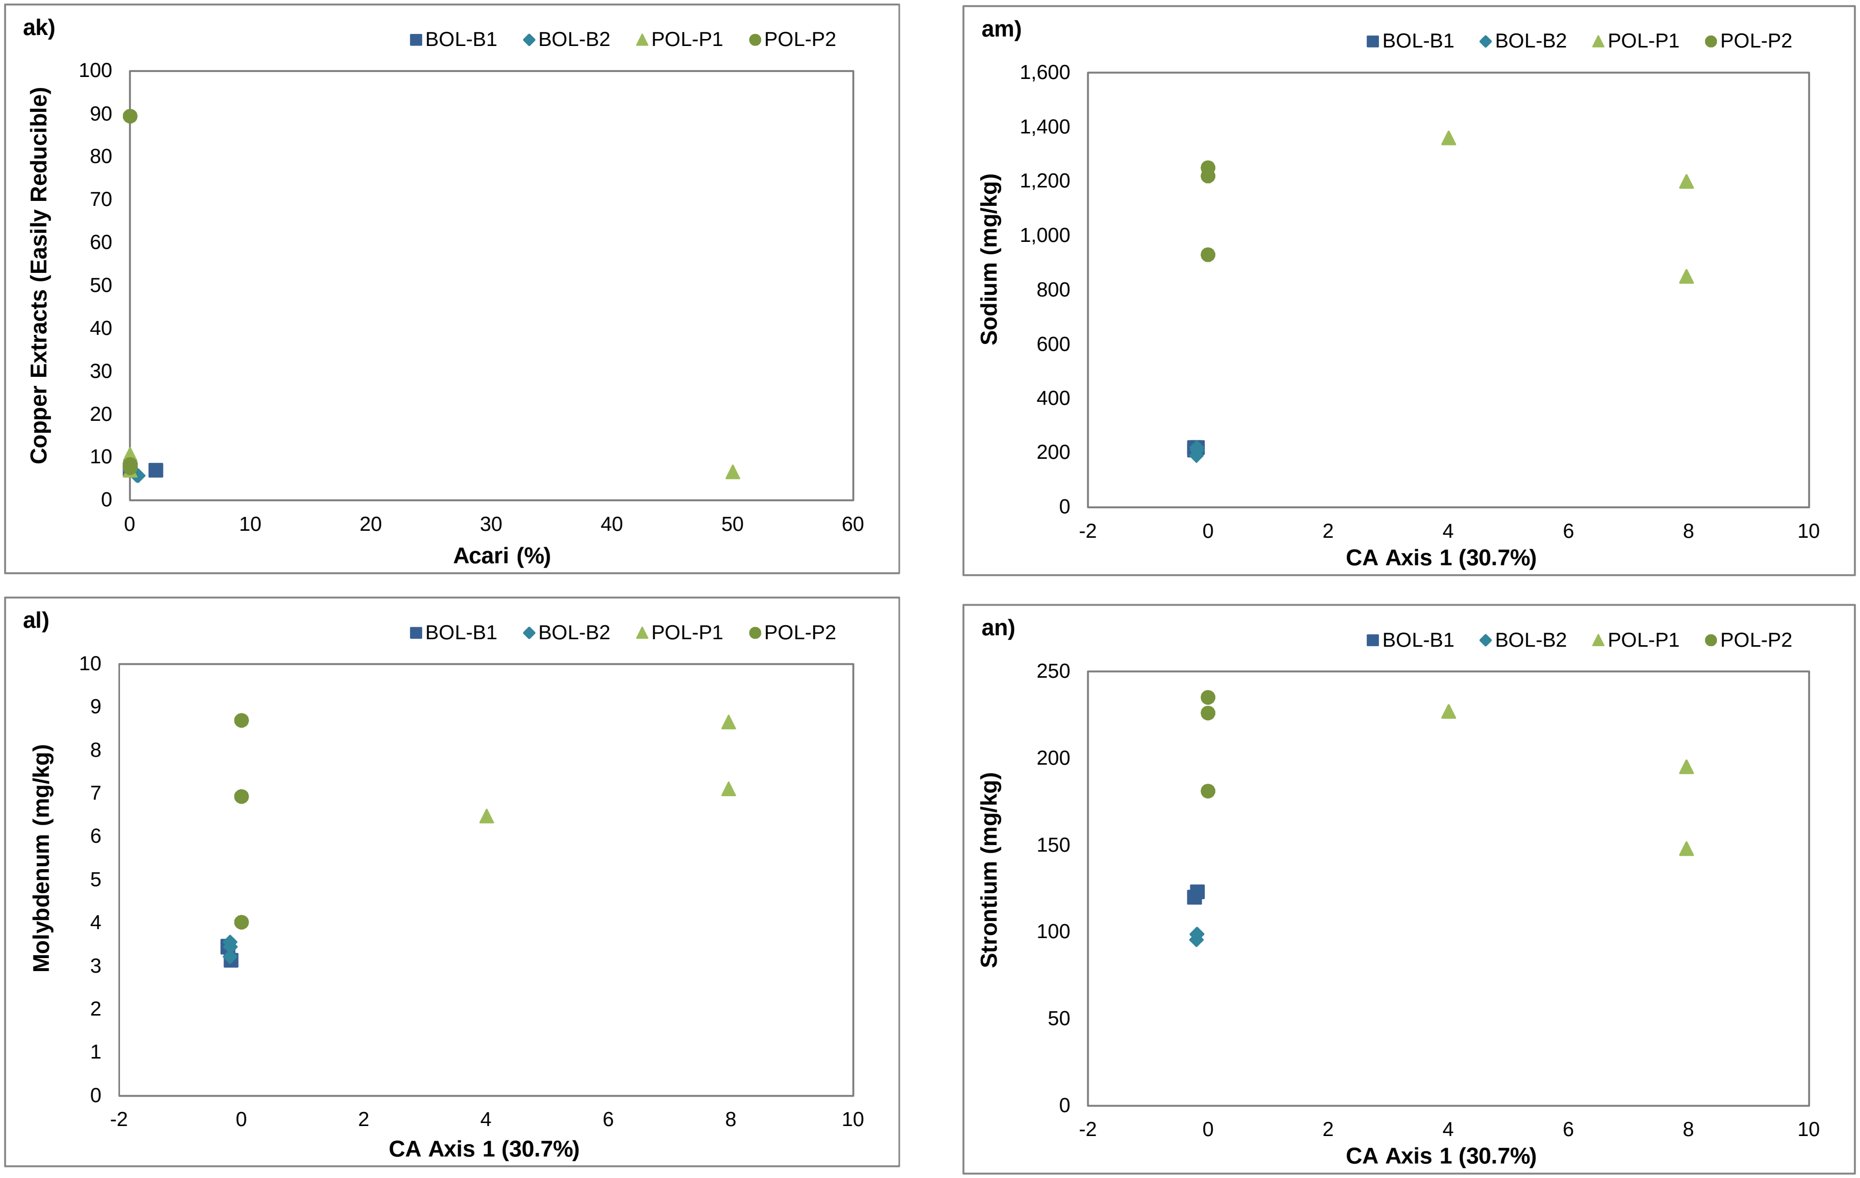

Figure I.6: Scatterplots of Spearman's correlation relationships ($p < 0.01$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake deep sampling areas.

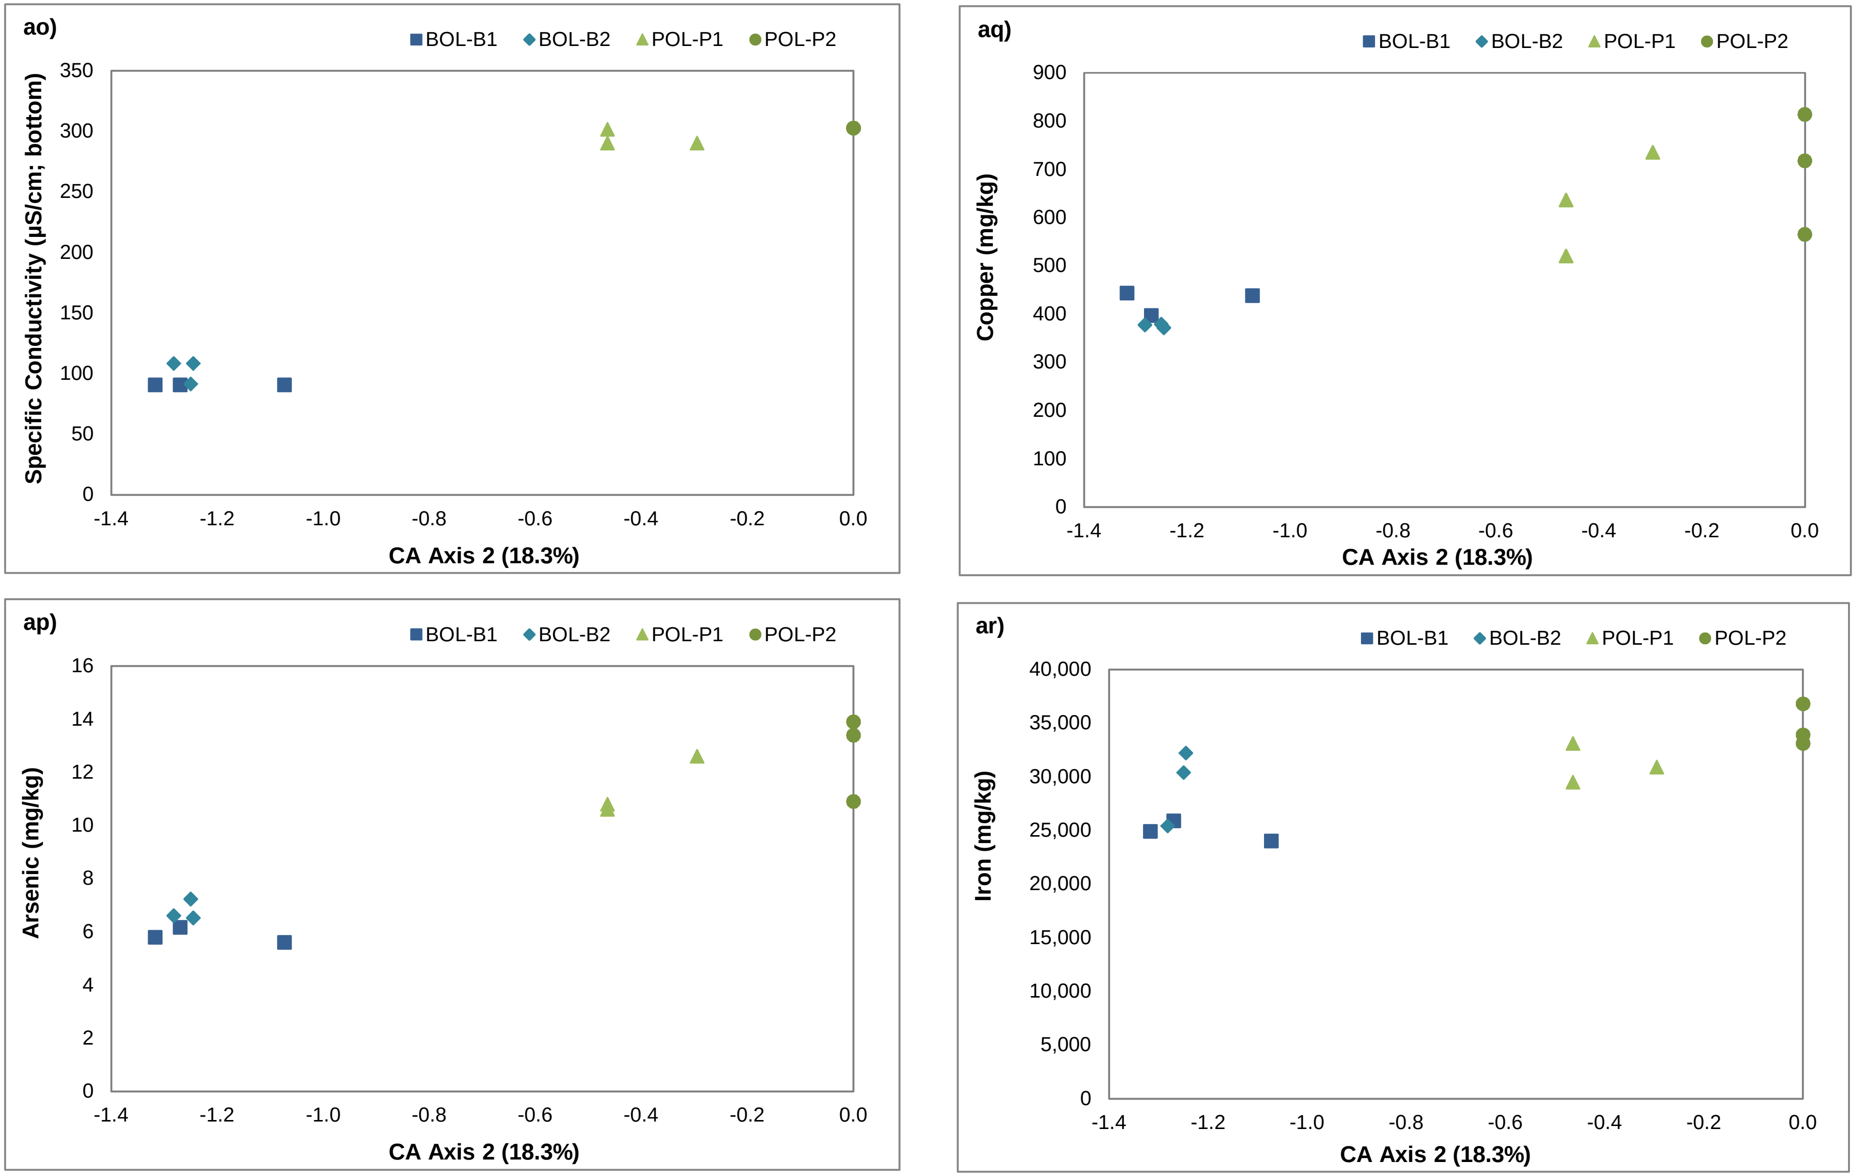

Figure I.6: Scatterplots of Spearman's correlation relationships ($p < 0.01$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake deep sampling areas.

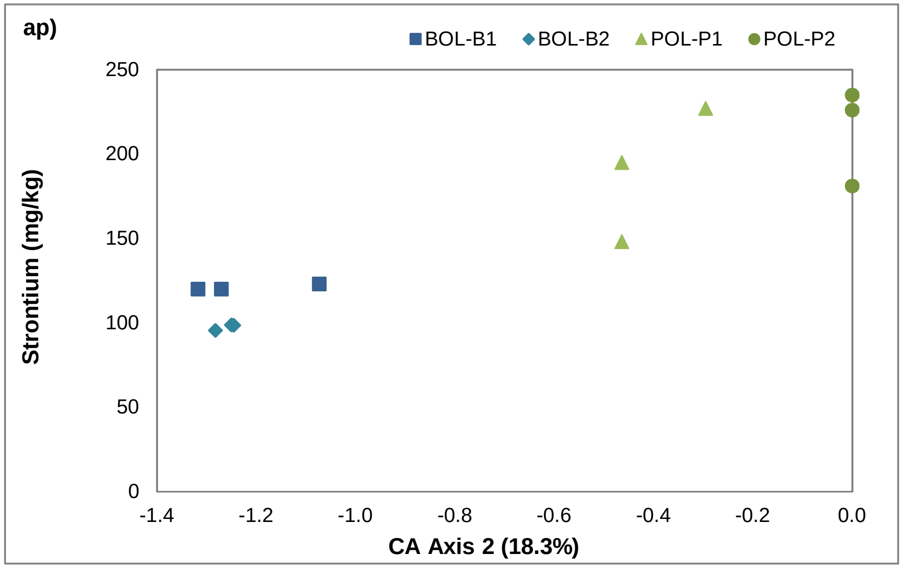

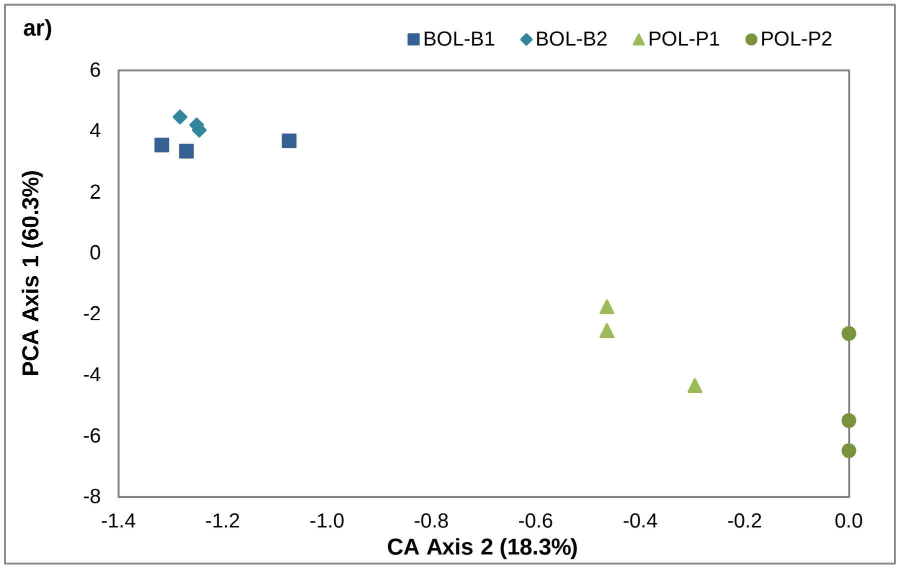

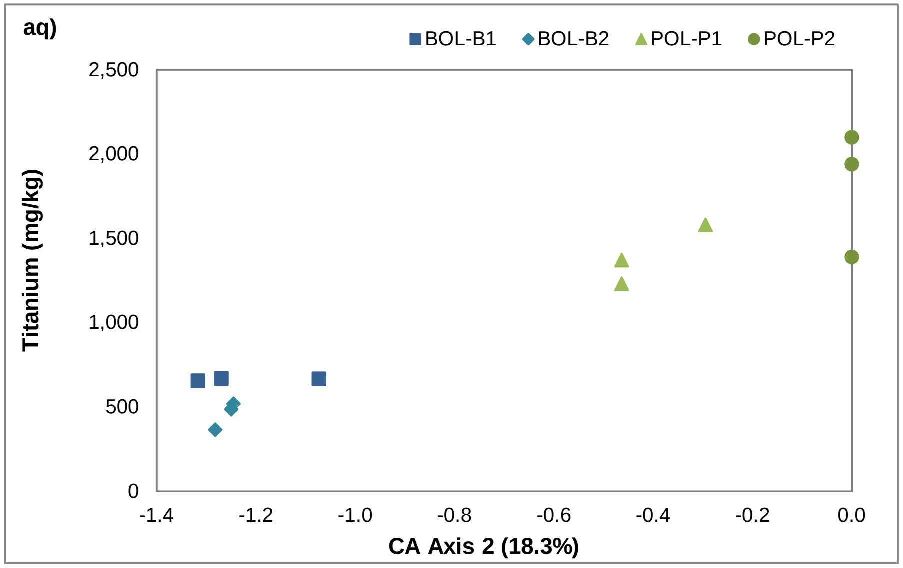

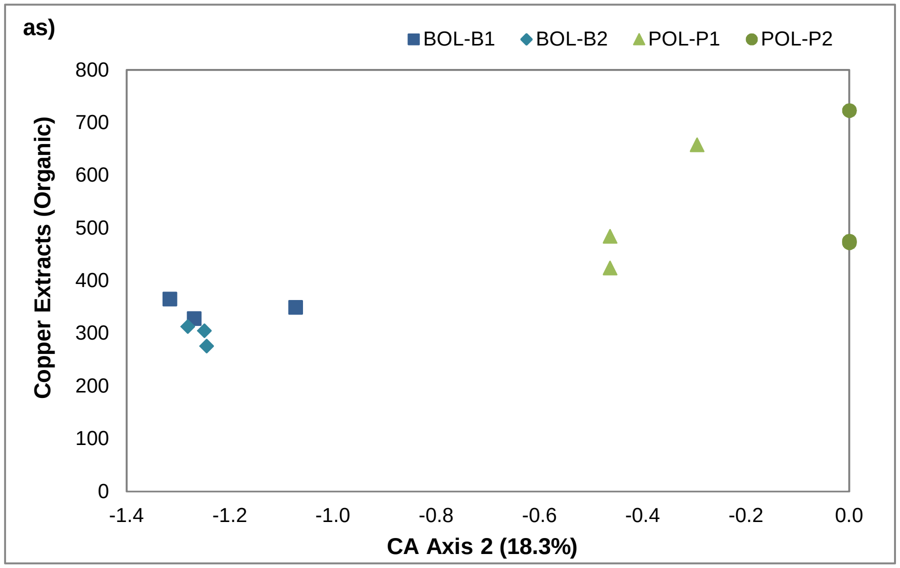

Figure I.6: Scatterplots of Spearman's correlation relationships ($p < 0.01$) between toxicity endpoints, benthic invertebrate community metrics and physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Polley and Bootjack Lake deep sampling areas.

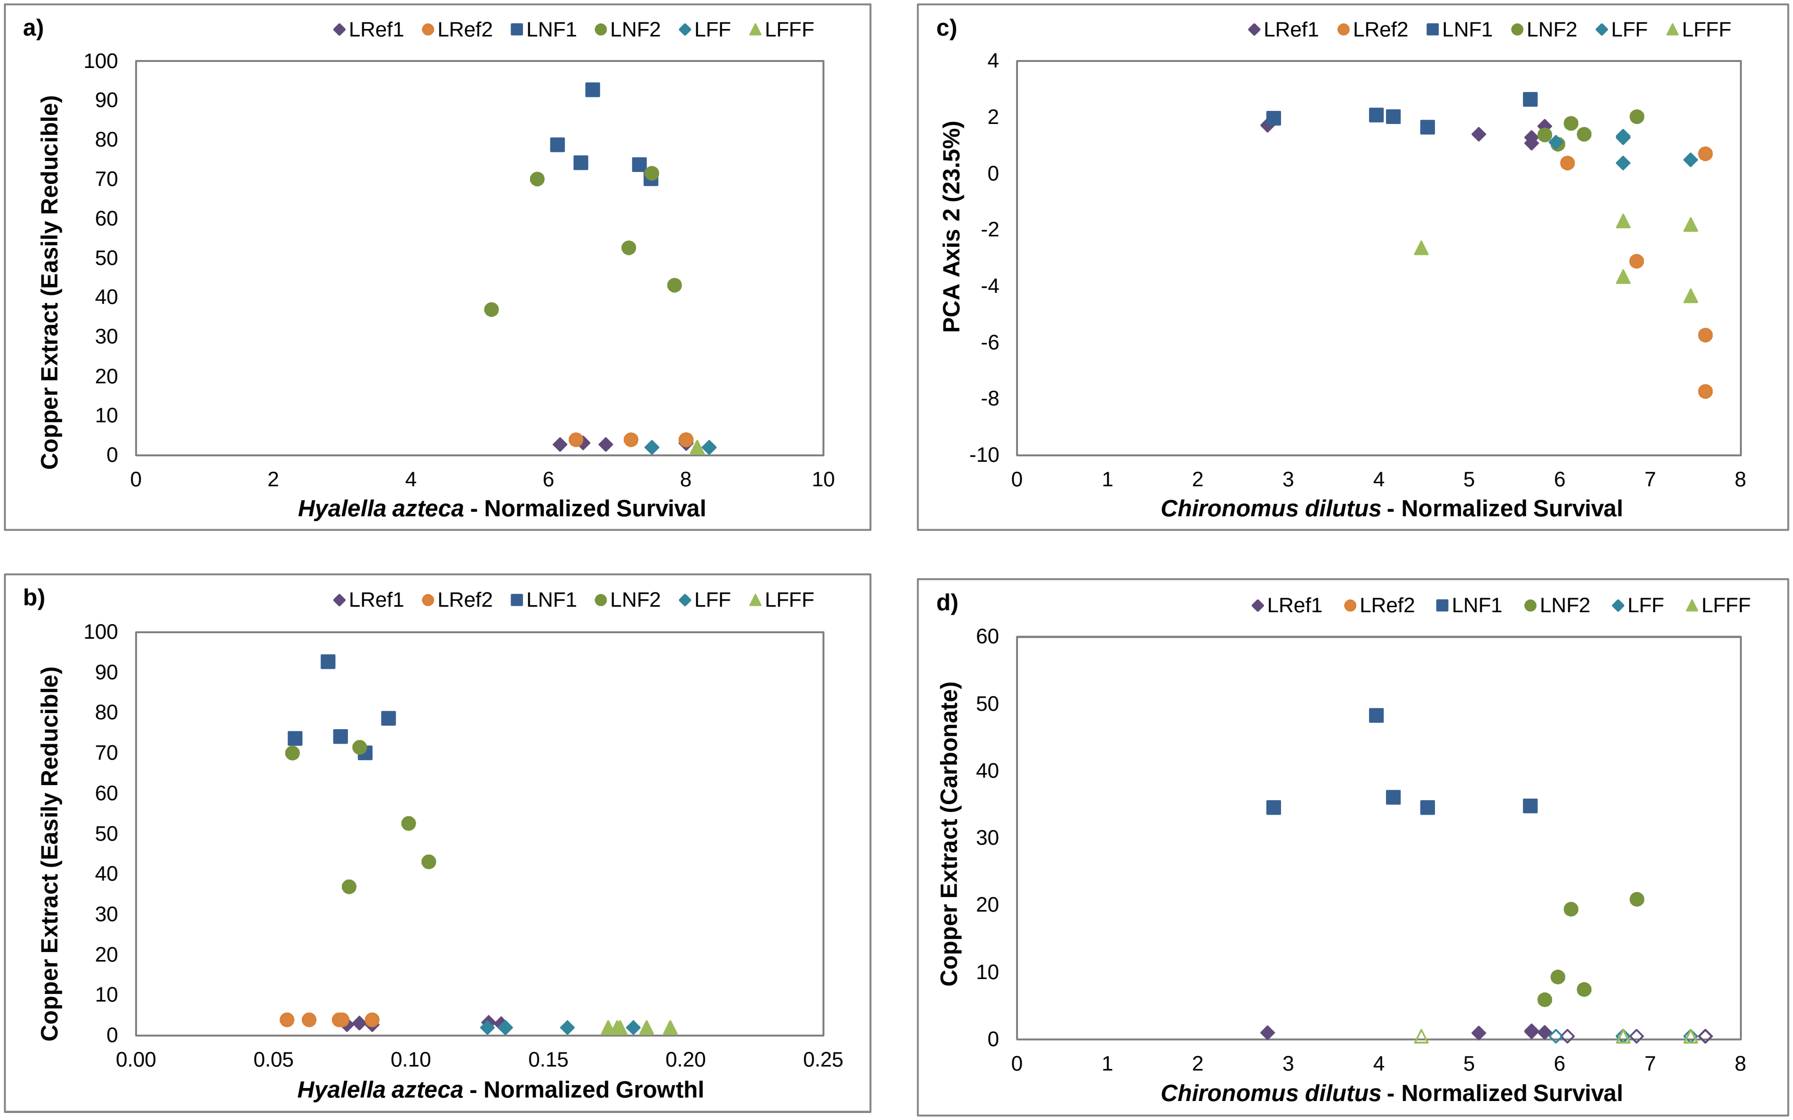

Figure I.7: Scatterplots of significant Spearman's correlation relationships ($p < 0.00009$) between toxicity endpoints, benthic invertebrate community metrics, sediment physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Quesnel Lake littoral sampling areas. Hollow symbols indicate values < MDL.

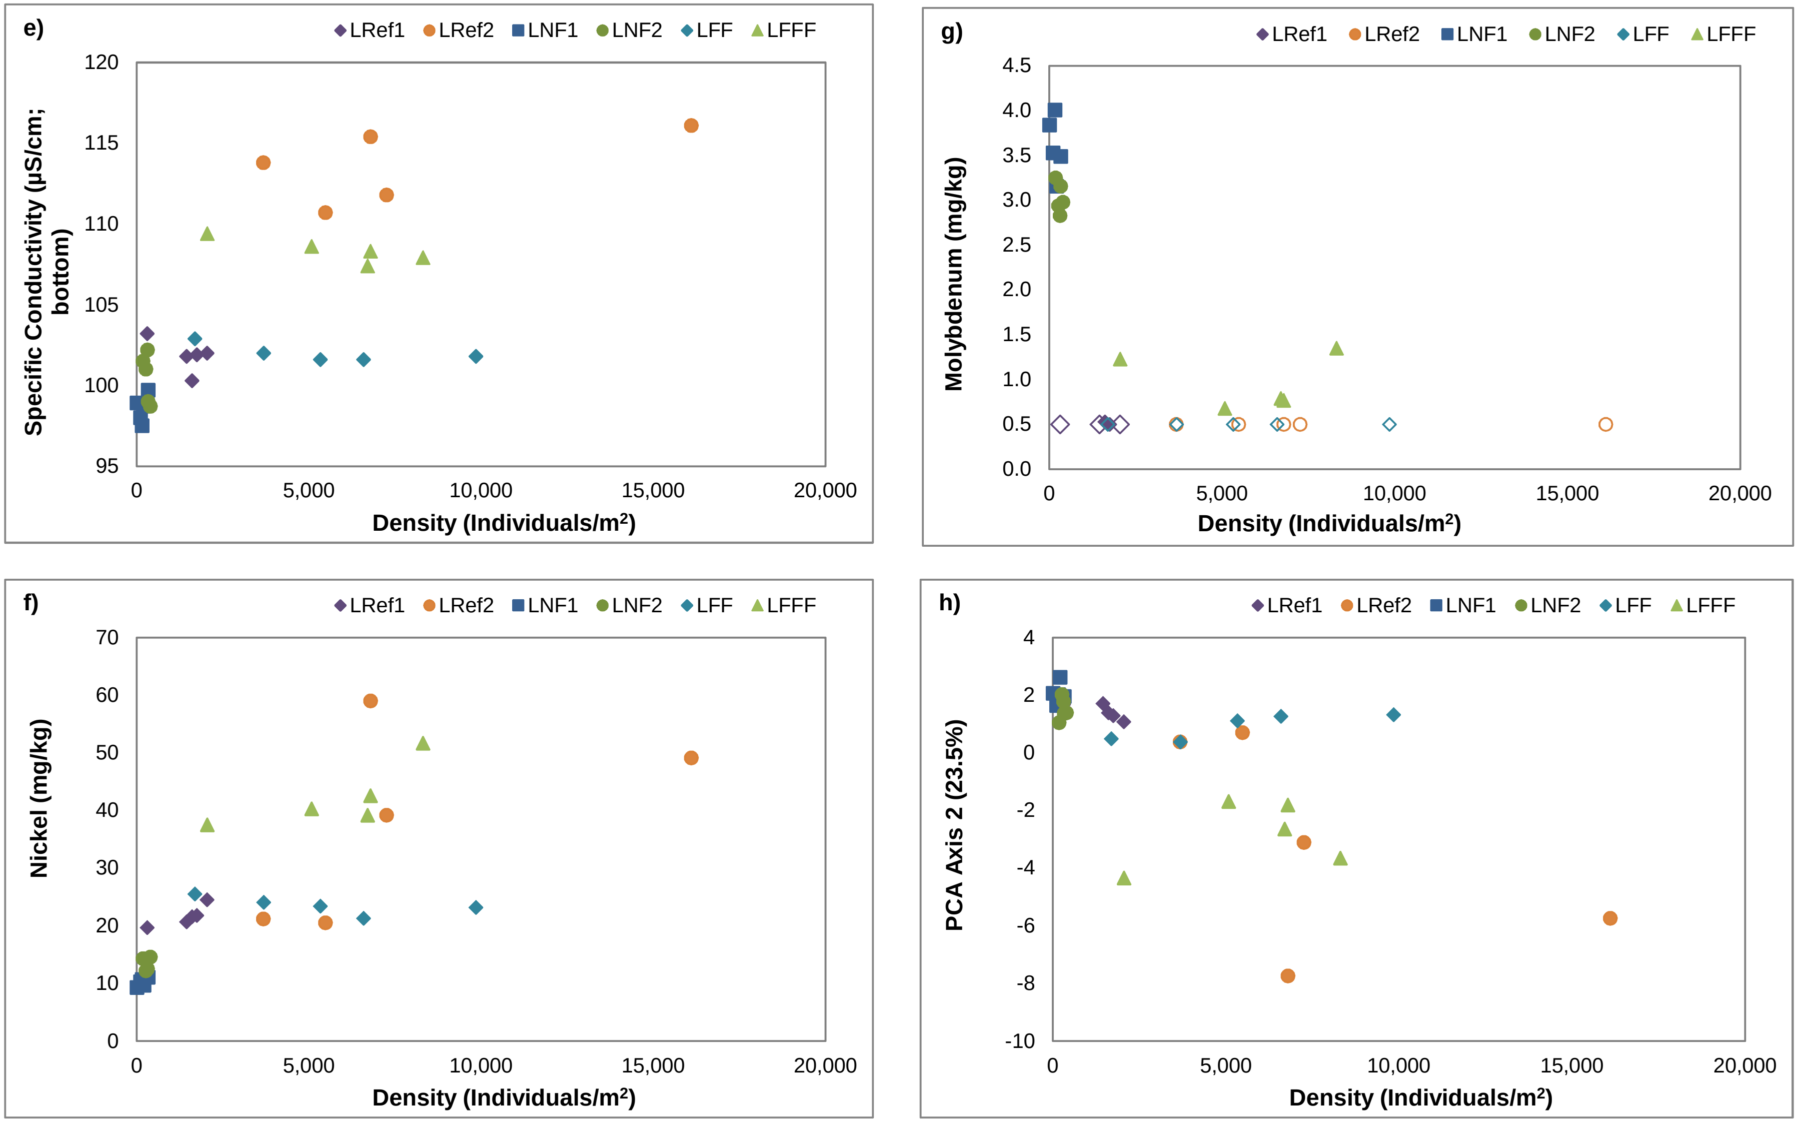

Figure I.7: Scatterplots of significant Spearman's correlation relationships ($p < 0.00009$) between toxicity endpoints, benthic invertebrate community metrics, sediment physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Quesnel Lake littoral sampling areas. Hollow symbols indicate values < MDL.

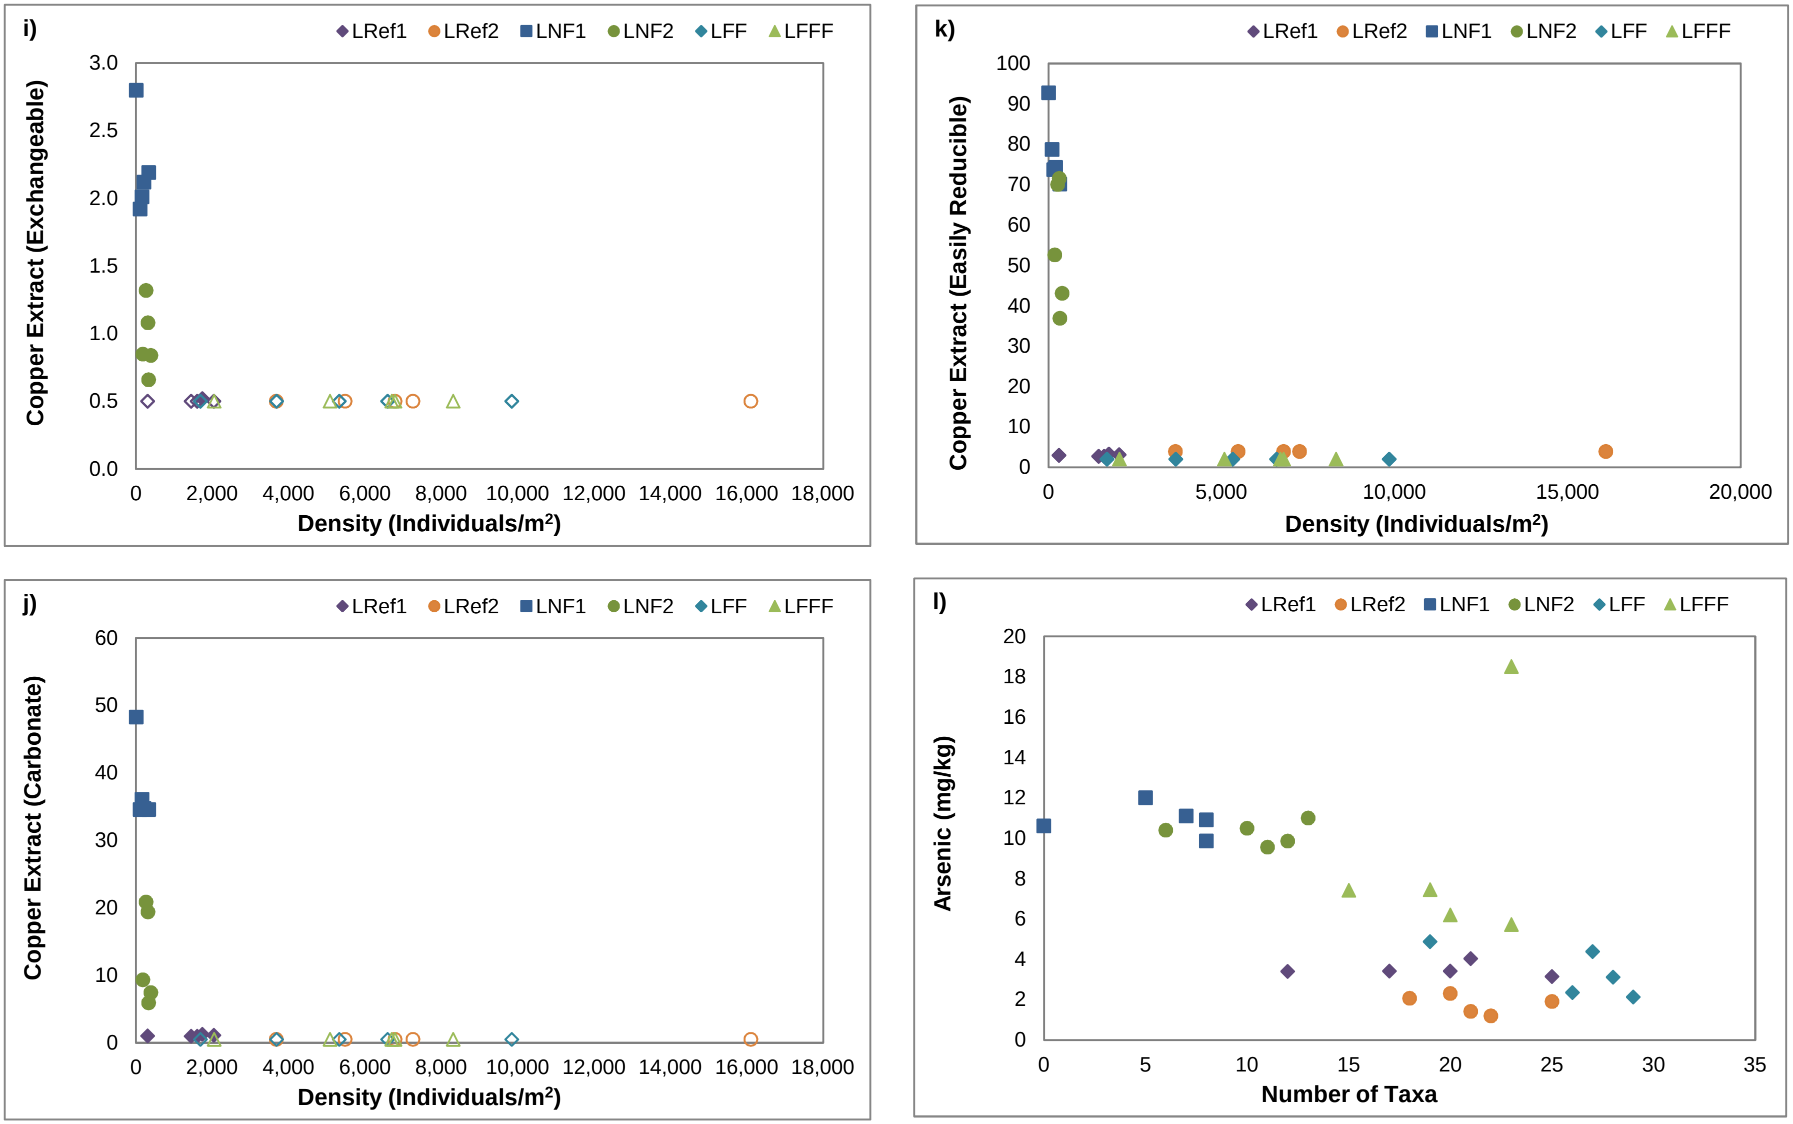

Figure I.7: Scatterplots of significant Spearman's correlation relationships ($p < 0.00009$) between toxicity endpoints, benthic invertebrate community metrics, sediment physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Quesnel Lake littoral sampling areas. Hollow symbols indicate values < MDL.

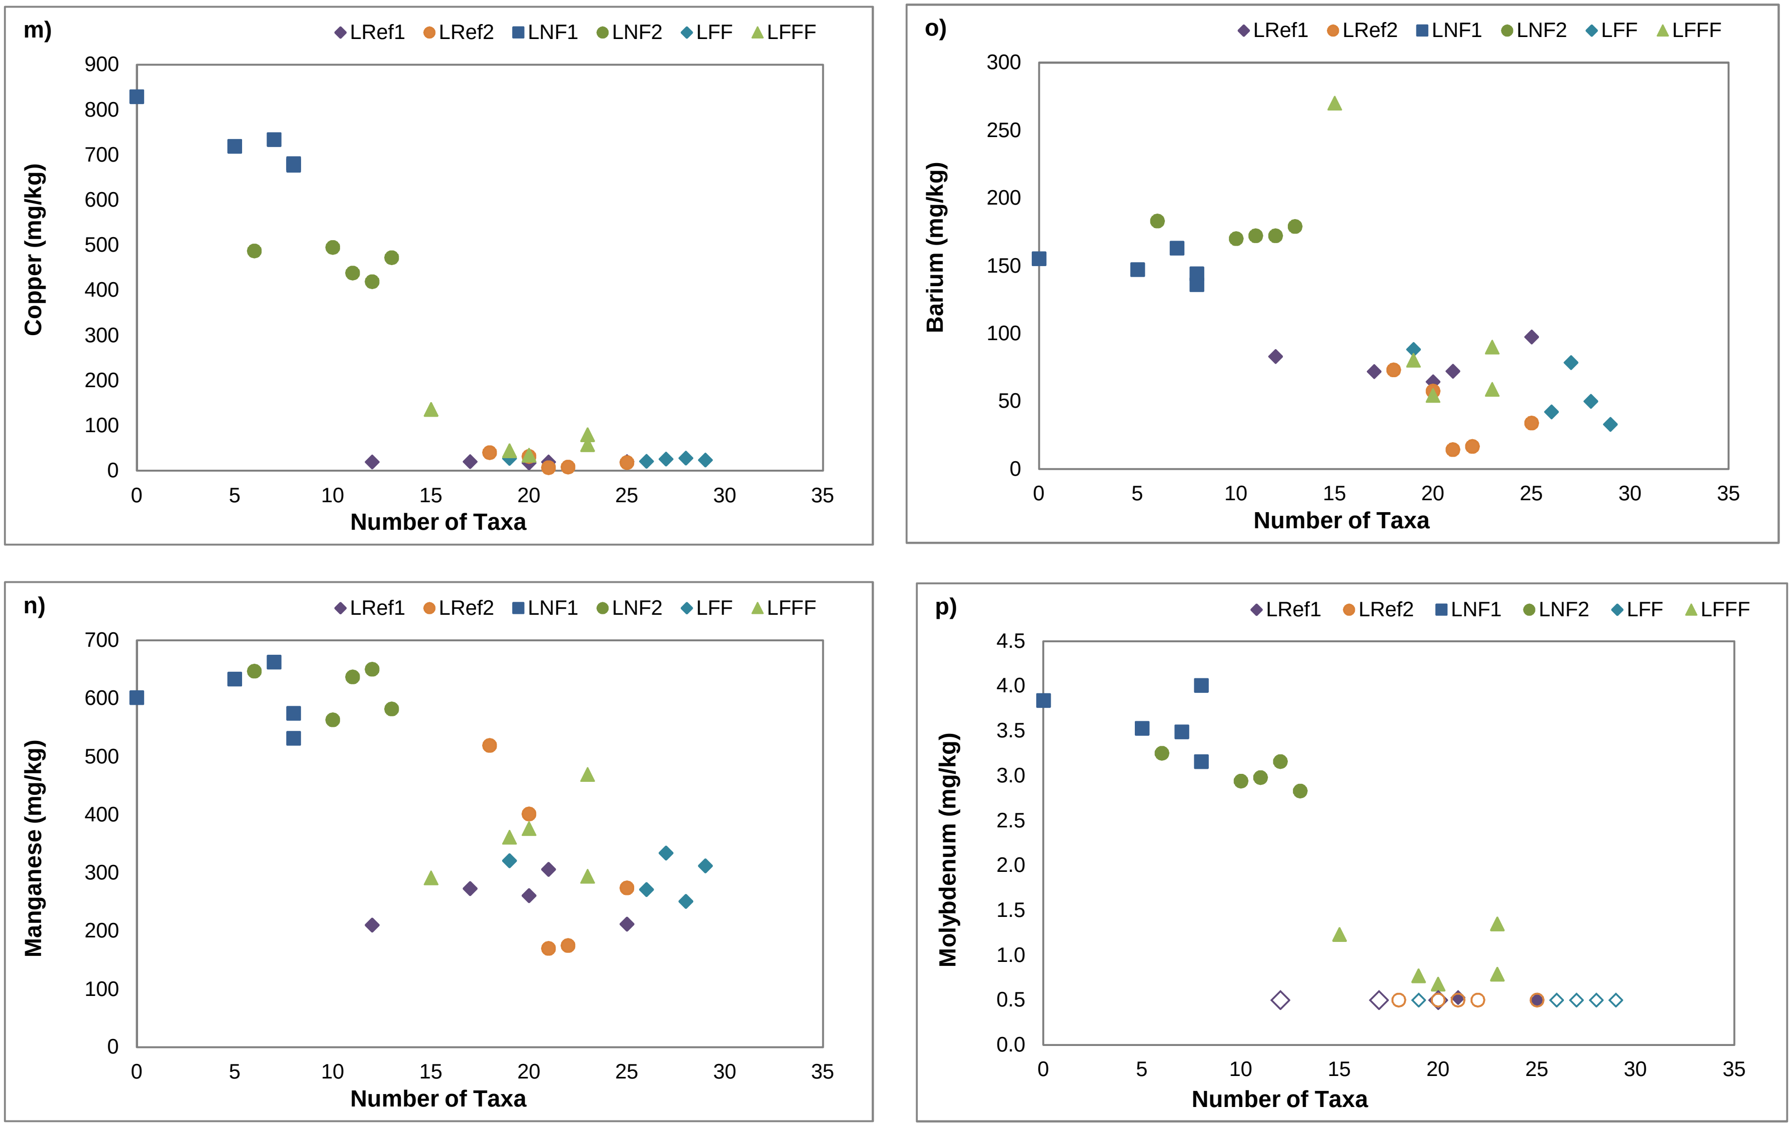

Figure I.7: Scatterplots of significant Spearman's correlation relationships ($p < 0.00009$) between toxicity endpoints, benthic invertebrate community metrics, sediment physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Quesnel Lake littoral sampling areas. Hollow symbols indicate values < MDL.

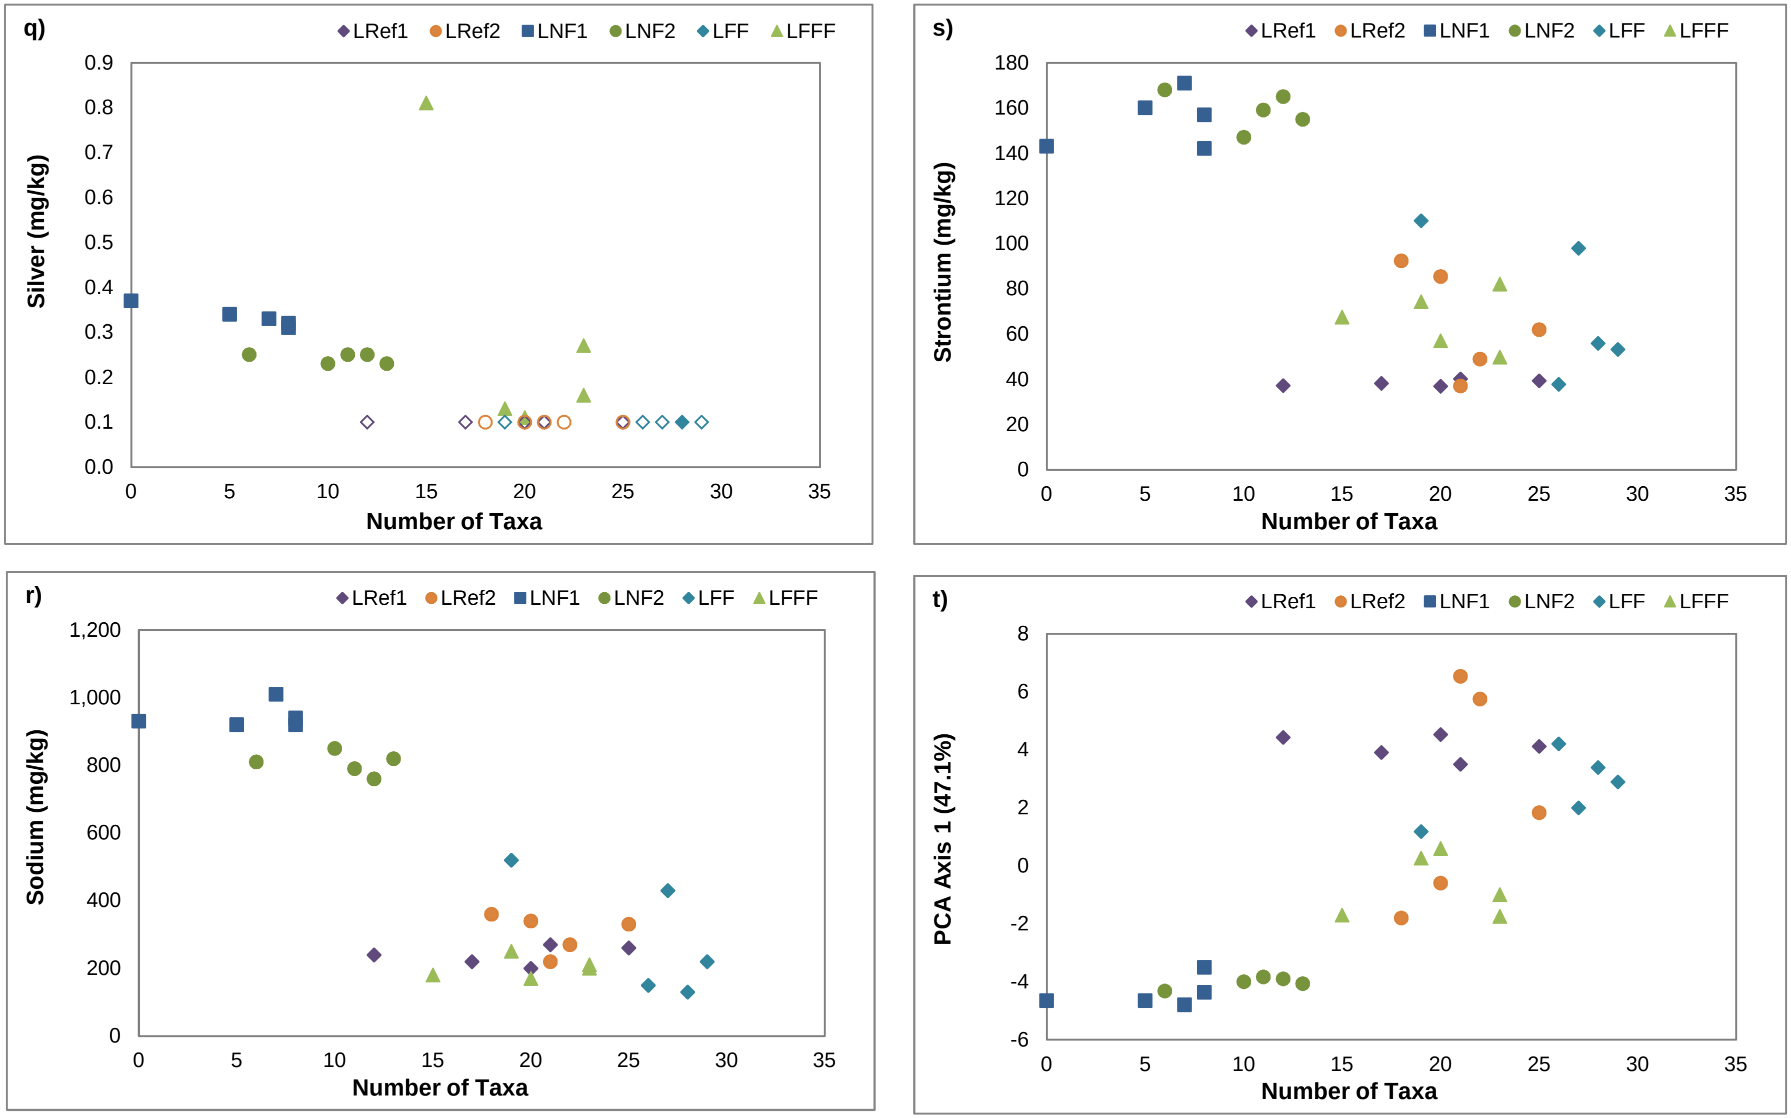

Figure I.7: Scatterplots of significant Spearman's correlation relationships (p < 0.00009) between toxicity endpoints, benthic invertebrate community metrics, sediment physical endpoints, parameters of interest, indicator parameters, PCA axes and copper extracts (Tessier extraction), Mount Polley Mine, 2014. Quesnel Lake littoral sampling areas. Hollow symbols indicate values < MDL.

REPORT

EXECUTIVE SUMMARY

The purpose of this surface Water Quality Impact Assessment (WQIA) was to characterize potential changes in downstream water quality, as a result of the August 4, 2014, tailings dam failure (the event) at the Mount Polley Mine. Changes in concentrations of contaminants identified by this report to be of potential concern following the event were evaluated in Hazeltine Creek and the downstream receiving environments Polley Lake, Quesnel Lake, and Quesnel River.

- Hazeltine Creek was directly impacted by the event. As a result of the large-scale physical impacts on this creek it was not considered to be fish habitat and thus was not defined as receiving environment for the assessment. Even though this creek is currently not considered to be an aquatic habitat, it was assessed based on comparisons to British Columbia Water Quality Guidelines (BC WQGs. Over the longer term, Mount Polley Mining Corporation (MPMC) intends to continue the restoration work of Hazeltine Creek, adding habitat features to support trout spawning and rearing in the upper reaches and spawning by sockeye and coho in the lower reaches.
- Receiving environments downstream of the tailings dam failure considered were Polley Lake, Quesnel Lake, and Quesnel River.

Changes in receiving environment water quality related to the event were evaluated based on a comparison to water quality guidelines and geochemical analysis of the waterborne and particulate material. The bioavailability of the copper in water was measured using aquatic toxicity tests with a variety of aquatic test species ranging from primary producers (plants), primary consumers (aquatic insects) to secondary consumers (fish). In general, immediately following the event, there were changes in water quality with concentrations of copper and turbidity exceeding water quality guidelines. However, the geochemical analysis indicated that the copper was tightly bound to particulate material indicating low potential for bioavailability. The low bioavailability of copper was confirmed by the results of the toxicity tests conducted during periods of higher turbidity as toxicity attributable to copper was not observed. Uncertainties in the assessment are documented for consideration in the development of water quality monitoring to support the Rehabilitation and Remediation Framework.

Hazeltine Creek

Creek water quality was influenced by the event and the subsequent erosion of exposed underlying native materials. Mitigation measures, such as construction of two sedimentation ponds in the lower creek and commissioned in December 2014, have reduced suspended particulate matter and concentrations of metals associated with suspended materials such, as aluminum and iron, in the water flowing out from Hazeltine Creek to Quesnel Lake. Post-event, total concentrations of these metals were higher than dissolved concentrations after the event, but total concentrations have now decreased such that total and dissolved concentrations are more similar. Total and dissolved copper concentrations decreased substantially over the post-event period from peak concentrations in August, but were still above BC WQGs in February 2015. More recently, stream erosion control works in Hazeltine Creek have concluded and Hazeltine Creek discharge turbidity is now typically in the single digits.

Receiving Environment

Suspended Particulate Matter

There were increased concentrations of suspended particulate matter in the waters of Polley Lake, Quesnel Lake, and Quesnel River due to the event. Over time, suspended particulates settled out in the receiving environment and the available data suggest that levels of particulate matter are no longer of concern. The larger suspended solids settled out more quickly following the event compared to the finer particulates measured by turbidity. The higher turbidity at depth in the lakes persisted until fall turnover. With turnover, turbidity at depth decreased, but increased in the near surface water. This relatively small change in surface turbidity resulted in a cloudy appearance within the West Basin. By early spring (March and April 2015), turbidity at surface and depth decreased to below BC WQGs for the protection of aquatic life except for some localised slightly elevated values close to the Hazeltine Creek mouth.

Observations of cloudy (turbid) water were recorded three times in late summer and early fall (late August, early September, early October) in Quesnel River. These cloudy-water events were the result of upwelling of deep, turbid water from Quesnel Lake at the outflow into Quesnel River as the lake responded to strong winds and currents (i.e., internal seiche). Turbidity in the river peaked in early December and declined to near baseline conditions by mid-February. As the turbidity in the main body of Quesnel Lake has returned to near baseline conditions, further cloudy water events in Quesnel River are not expected.

Phosphorus and Metals

An increase in the nutrient phosphorus was also observed in Polley and Quesnel Lakes due to the event. The potential impact of changes in phosphorus on aquatic life in Polley and Quesnel Lakes is discussed further elsewhere in the Quesnel and Polley Lakes Aquatic Productivity Impact Assessment.

Concentrations of metals immediately following the event through to April 2015, were not of potential concern with regards to drinking water sources or wildlife, with the exception of molybdenum in Polley Lake. The concentrations of molybdenum decreased over the winter and were no longer of potential concern by April. Although elevated immediately after the event with respect to BC WQGs for the protection of aquatic life, total concentrations of several metals decreased over the post-event period such that by April, only concentrations of total (but not dissolved) copper were above the water quality guideline for the protection of aquatic life in Quesnel Lake

The BC WQGs for the protection of aquatic life are a useful tool to identify chemicals in water that may cause adverse effects, but they are conservative in their derivation and should not be used for remediation purposes. Ideally, more direct measures of toxicity should be used that take into consideration the mixture of potential contaminants and other parameters in the water. The findings of toxicity testing with water samples collected throughout the post-event period, using three trophic levels of test species covering primary producers, primary consumers and secondary consumers, , together with the several geochemical lines of evidence, provided a more realistic assessment of potential impact of changes in water quality to aquatic life. These findings indicate that, although there were measured changes in water quality, the evidence available to date does not indicate that the constituents of the TSF materials resulted in toxicity in the water column. We note that this report is an interim report and that additional studies remain ongoing or are planned.

STATEMENT OF LIMITATIONS

This report was prepared for the exclusive use of MPMC. The inferences concerning the data, site and receiving environment conditions contained in this report are based on information obtained during investigations conducted at the site by Golder Associates Ltd. (Golder), other consultants and MPMC, and are based solely on the condition of the site at the time of the site studies and subsequent investigations and remediation and other information obtained by Golder, as described in this report. Soil, surface water and groundwater conditions may vary with location, depth, time, sampling methodology, analytical techniques and other factors.

In evaluating the subject site and water quality data, Golder has relied in good faith on information provided. The factual data, interpretations and recommendations pertain to a specific project as described in this report, based on the information obtained during the assessment by Golder on the dates cited in the report, and are not applicable to any other project or site location. Golder accepts no responsibility for any deficiency or inaccuracy contained in this report as a result of reliance on the aforementioned information.

The findings and conclusions documented in this report have been prepared for the specific application to this project, and have been developed in a manner consistent with that level of care normally exercised by environmental professionals currently practising under similar conditions in the jurisdiction. Golder makes no other warranty, expressed or implied and assumes no liability with respect to the use of the information contained in this report at the subject site, or any other site, for other than its intended purpose.

Any use which a third party makes of this report, or any reliance on or decisions to be made based on it, are the responsibility of such third parties. Golder accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or action based on this report. All third parties relying on this report do so at their own risk. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely upon the electronic media versions of Golder’s report or other work product. Golder is not responsible for any unauthorized use or modifications of this report.

MPMC may rely on the information contained in this report subject to the above limitations.

Golder makes no other representation whatsoever, including those concerning the legal significance of its findings, or as to other legal matters touched on in this report, including, but not limited to, ownership of any property, or the application of any law to the facts set forth herein.

If new information is discovered during future work, including excavations, sampling, soil boring, predictive geochemistry or other investigations, Golder should be requested to re-evaluate the conclusions of this report and to provide amendments, as required, prior to any reliance upon the information presented herein. The validity of this report is affected by any change of site conditions, purpose, development plans or significant delay from the date of this report in initiating or completing the project.

1.0 INTRODUCTION

On August 4, 2014, a failure of the Tailings Storage Facility (TSF) embankment and subsequent debris flow occurred at the Mount Polley Mine. The purpose of this Surface Water Quality Impact Assessment (WQIA) was to characterize potential changes in downstream water quality as a result of the Tailings Dam Failure (the event). Changes in water quality were assessed by comparing pre- and post-event water quality, where pre-impact data were available, and by evaluating post-event data in the context of applicable water quality guidelines (WQGs) with consideration of site-specific conditions. The WQIA scope focussed on an evaluation of water quality data available for surface waters located within seven study areas defined for the Post-Event Environmental Impact Assessment Report (PEEIAR) in (Golder 2015a) and shown on Figure 1.

To characterize potential event-related changes in downstream water quality, the WQIA evaluated changes in contaminants of potential concern (COPCs) during the post-event assessment period. The WQIA first defines spatial and temporal boundaries in Section 2. The assessment approach is described in Section 3, along with specific methods used to evaluate water quality changes that may have occurred as a result of the event. The impact assessment presented in Section 4 focusses on the evaluation of COPCs over the post event period in Hazeltine Creek and the receiving environment (i.e., Polley Lake, Quesnel Lake and Quesnel River). Changes in receiving environment water quality related to the event in terms of COPC guideline comparisons are discussed, as well as the findings of site-specific studies to evaluate contaminant bioavailability. Interim findings based on this assessment are presented in Section 5. Uncertainties in the impact assessment are discussed in Section 6 for consideration in the development of water quality monitoring to support the Rehabilitation and Remediation Framework.

2.0 ASSESSMENT BOUNDARIES

2.1 Study Areas

The PEEIAR provides a description of the event, including estimates of the volumes of water, tailings, and Hazeltine debris flow scour sediments that were released. It also provides a description of the evolution of the event, areas of impact and the spatial boundary of the PEEIAR study area.

The WQIA focussed on surface water quality changes in six of the seven areas downstream of TSF and the Polley Lake "plug" identified by Golder (2015a)[1] (Figure 1), which are as follows:

- Upper Hazeltine Creek (Area 4);
- Lower Hazeltine Creek (Areas 6 and 7);
- Polley Lake (Area 3);
- Quesnel Lake (Area 8); and,
- Quesnel River (Area 9).

The spatial boundaries of the WQIA covered Hazeltine Creek located immediately downstream of the tailings dam failure and the area most directly impacted by event. As a result of the physical impacts on Hazeltine Creek, the creek was not considered to be fish habitat during the post event period and thus was not defined as a receiving environment. Receiving environments located downstream of the tailings dam failure were determined to be Polley Lake, Quesnel Lake, and Quesnel River. While the mouth of Edney Creek was impacted by the physical effects of the debris flow, Edney Creek water quality is determined by a watershed that was not influenced by the event and thus an impact assessment of Edney Creek water quality was not undertaken.

A brief description of Hazeltine Creek and each receiving environment with respect to pre-event surface water quality is presented below.

2.1.1 Hazeltine Creek

Hazeltine Creek flows from Polley Lake into the West Basin of Quesnel Lake, a distance of approximately 9.2 km. Minnow Environmental Inc. (Minnow 2014) provides summaries of surface water quality in upper Hazeltine Creek during three time periods: baseline (pre-1997), post-baseline operations (1997 to 2008), and recent operations prior to the event (2009 to 2013). Based on the most recent pre-event summary, surface waters in Hazeltine Creek were generally characterized as clear (median turbidity of 1.4 nephelometric turbidity units [NTU], range 0.28 to 16 NTU), alkaline (median pH of 7.9, range 6.7 to 9.1) and moderately soft in hardness (median hardness of 80 milligrams per litre [mg/L] as $CaCO_3$, range 39 to 820 mg/L). Based on median concentrations, total phosphorus (TP) and copper were higher than British Columbia water quality guidelines (BC WQGs)[2], but other parameters were less than BC WQGs (Minnow 2014). Upper concentration limits (defined by 95th percentile concentrations) ofllr total suspended solids (TSS), turbidity, nitrate, nitrite, aluminum, and copper were higher than BC WQGs.

---

[1] Post-event water quality data were not available for Hazeltine Canyon [Area 5] but the water quality in the canyon is considered to be sufficiently represented by water quality upstream and downstream of the canyon.

[2] In this document, reference to BC WQG is intended to mean the water quality guidelines for freshwater aquatic life, except where specifically stated to the contrary.

2.1.2 Receiving Environment

2.1.2.1 Polley Lake

Polley Lake is a long (6.17 kilometre [km]) narrow (0.65 km) lake situated adjacent to the Mount Polley Mine within a watershed area of 17.1 square kilometres (km^2). Minnow (2014) estimated the hydraulic residence time of the lake as approximately 16.2 years. The lake has a mean depth of 18 metres (m) and maximum depths of 35 m in the southeast basin and 33 m in the northwest basin. The main inflow to the lake is from the Frypan Lake sub-watershed situated to the north. The present configuration of Polley Lake is not its natural form. Polley Lake was dammed and its drainage modified to provide water to hydraulic mining activities that occurred in the region during the early 1900's.

Polley Lake is a dimictic lake that mixes from the surface to the lake bottom twice each year. Thermal stratification occurs in summer; a thermocline typically forms at a depth between 5 and 15 m (Minnow 2014). Hypoxic conditions generally occur at depths greater than 20 m, with dissolved oxygen (DO) concentrations less than 5 mg/L (Minnow 2014). Trophic status of the lake changed from oligotrophic/mesotrophic prior to mine development to mesotrophic/eutrophic in 2012 (Minnow 2014).

Minnow (2014) summarized a sub-set of water quality data collected prior to the event (2009 to 2013) at two stations (P1 and P2) and two depths (surface and bottom) in Polley Lake. Based on this summary, water in Polley Lake is characterized as clear (median turbidity of 1.1 NTU), slightly alkaline (median pH 8.9 at surface and 7.7 at bottom), moderately soft in hardness (median hardness of 104 mg/L as $CaCO_3$) based on the scale described by McNeely et al. (1979), with low sensitivity to acid inputs (median total alkalinity of 79 mg/L as $CaCO_3$) based on the scale of acid sensitivity for lakes by Saffran and Trew (1996). Median concentrations of total dissolved solids (TDS) at surface and bottom ranged from 132 to 135 mg/L. Pre-event, median concentrations of chloride, sulphate, nitrate, nitrite, and ammonia were less than applicable BC WQGs as were median concentrations of metals[3] (Minnow 2014).

2.1.2.2 Quesnel Lake

Quesnel Lake is a large, deep fjord lake with a surface area of 266 km^2; the lake is comprised of East, West and North Arms. It is the deepest fjord-type lake in the world with a maximum depth of 511 m in the East Arm (Laval et al. 2008). The West Basin is a shallower (113 m maximum depth) portion of the West Arm that is separated from the rest of the lake by a shallow sill that is approximately 35 m deep, near Cariboo Island, and is considered the area between Cariboo Island and the Quesnel River (Laval et al. 2008). The West Basin has vertical mixing that is typical of temperate lakes, with thermal stratification for most of the year interrupted by brief turnover periods in the spring and the fall when vertical density gradients are lowest. In the deeper portions of the lake, seasonal turnover events only occur in the upper 100-200 m of the water column due to changes in temperature-density relationships with increased pressure at greater depths. The key drivers of circulation patterns in Quesnel Lake have been studied in detail (see James 2004; Laval et al. 2008; Laval et al. 2012; Potts 2004) and are most recently described in TetraTech EBA Inc. (Tetra Tech 2015).

---

[3] The term "metal" is used in this report to encompass metals, metalloids (e.g., arsenic) and non-metal elements (e.g., selenium).

Limnological data were collected between 1985 to 1988 and in 1990 by Nidle et al. (1994). These data provided mean values for thermocline depth (12.4 m), epilimnetic temperature (12.4 degrees Celcius [°C]), and euphotic zone depth (15.5 m) (Shortreed et al. 2001). Mount Polley Mine is located near the West Basin of Quesnel Lake, which received inputs from the event via water and debris flows from Hazeltine Creek.

Nidle et al. (1994) also collected water chemistry data related to lake productivity, specifically, nutrients, pH, alkalinity, and TDS. At the time of sampling, mean annual lake-wide concentrations of TP (0.0027 mg/L), nitrate (0.104 milligrams of nitrogen per litre [mg N/L]), and total chlorophyll (1.03 micrograms per litre [µg/L]) were within the range for oligotrophic lakes (Shortreed et al. 2001). Annual lake-wide summaries indicated that the lake was slightly alkaline (average pH 7.2 to 7.8), low in TDS (59 to 66 mg/L), with low sensitivity to acid inputs (total alkalinity from 44 to 50 mg/L as $CaCO_3$) (Nidle et al. 1994).

More recent nutrient data obtained from the British Columbia Ministry of the Environment (BC MoE) suggests that Quesnel Lake has maintained its oligotrophic status (Appendix A). In water samples collected between August 2004 and September 2006, TP concentrations were within the range for oligotrophic lakes according to the Canadian Council of Ministers of the Environment (CCME 2004) trophic status classification for lakes. Total nitrogen concentrations (median of 0.17 mg/L) were similar to concentrations of nitrate measured previously by Nidle et al. (1994).

Limited pre-event water chemistry data are available for Quesnel Lake, with no available turbidity or metals data (Appendix A). Concentrations of ammonia, nitrate, and nitrite were less than their corresponding BC WQGs.

2.1.2.3 Quesnel River

Quesnel River is a major tributary of the Fraser River located in the Cariboo District of central British Columbia. From its outflow at Quesnel Lake, near the town of Likely, it flows 100 km to the northwest, descending 2500 m, to its confluence with the Fraser River at the town of Quesnel. The river is situated in a basin with an area of approximately 11,500 km^2 and has a mean discharge rate of 230 cubic metres per second (m^3/s) (Reynoldson et al. 2010).

Limited historical water quality data for Quesnel River were obtained from the BC MoE and are mostly restricted to the Likely Bridge near the town of Likely (Appendix A). During the sampling period (1972 to 1987) the surface water at Likely was well-oxygenated (DO from 8.5 to 13.4 mg/L), clear (turbidity from 0.2 to 1.4 NTU) and characterized as soft in hardness (46 to 56 mg/L as $CaCO_3$). A pH range of 6.5 to 8.1 was identified for this river with all measurements within the BC WQG pH range. Median concentrations of chloride, ammonia, nitrate, nitrite, and sulphate were less than their corresponding BC WQGs. Metals data were limited for Quesnel River; however, data for aluminum, chromium, copper, iron, lead, manganese, and zinc indicated that concentrations for these metals were less than BC WQGs. At the Gravelle Ferry Bridge, 50 km downstream of Likely, during the sampling period (2011 to July 2014), DO ranged from 9.3 to 10.5 mg/L, pH ranged from 7.8 to 8.0, and hardness ranged from 51 to 63 mg/L. Turbidity ranged from 0.18 to 47 NTU. Data for total phosphorus, total chromium, total copper, total iron, total zinc, and dissolved aluminum indicated that 95th percentile concentrations exceeded BC WQGs. These exceedances indicate that inputs of particulate bound metals to the river exist downstream of Likely.

2.2 Temporal Boundaries

The WQIA focussed on an evaluation of water quality changes after the event. Water quality monitoring is ongoing; however, for the purposes of this report, a data time period cutoff had to be set. For the purposes of initial identification of COPCs, the post-event time period was defined as August 2014 to February 2015, which was the time period for which water quality data were available,. For the evaluation of chemical COPCs in the receiving environment this assessment period was extended from February to April 2015 as new data became available. The assessment period was extended for these parameters because data collected after lake turn over were limited by a cessation of sample collection at the majority of lake stations during winter due to safety and logistical concerns. Consideration of March and April data expanded the post lake turnover dataset for these stations.

The pre-event time period represented the period of record for which water quality data were available for each of the study areas identified in Section 2.1. The compilation of pre-event water quality data is described further in Section 3.1, but data were available for Polley Lake (1995 to 2014), Hazeltine Creek (1990 to 2014), Quesnel Lake (2004 to 2006) and Quesnel River (1972 to 1987 and 2011 to 2014).

3.0 IMPACT ASSESSMENT APPROACH AND METHODS

3.1 Pre-Event Surface Water Quality

3.1.1 Data Compilation

Pre-event surface water quality data were compiled to provide context for the post-event WQIA. Data search efforts are detailed in Appendix A with an overview provided below.

The data search focused on surface water quality data collected in the spatial areas described in Section 2.1; i.e., Polley Lake, Hazeltine Creek, Quesnel Lake and Quesnel River. MPMC has a large baseline and pre-event water quality data set that includes water chemistry data related to the TSF supernatant, Polley Lake, Hazeltine Creek, and the mouth of Edney Creek (Table 3-1). These data were considered to be sufficiently comprehensive to enable a background characterization for those areas, such that only a search for Quesnel Lake and Quesnel River pre-event data was undertaken.

Representatives of the following agencies and groups were contacted to identify pre-event data in their possession or if they had knowledge of other data sources for Quesnel Lake and Quesnel River:

- BC MoE;
- BC Ministry of Forests, Lands and Natural Resource Operations;
- Fisheries and Oceans Canada;
- Environment Canada;
- BC Interior Health;
- local consultants who have worked in the Likely and Quesnel Lake area; and,
- regional researchers at the University of British Columbia (UBC) and University of Northern British Columbia.

Based on the results of this inquiry, a more limited pre-event data set was compiled for Quesnel Lake and Quesnel River (BC MoE data) compared to the pre-event data available for Polley Lake and Hazeltine Creek (MPMC data). Data for Quesnel River at the town of Likely included water samples analysed for a sub-set of chemical parameters including metals, nutrients, and major ions, with the most recent pre-event sample collected more than 25 years ago. Sampling at the Likely Bridge was re-commenced post-event. Data for Quesnel River 50 km downstream of Likely at the Gravelle Ferry Bridge was limited to six samples collected between June 2011 and July 2014. Water samples were analysed for a sub-set of parameters including turbidity, metals, nutrients, and major ions; TSS was not measured.

The Quesnel Lake dataset was comprised of data from nutrient-related monitoring surveys that were primarily focused around Horsefly Bay just east of Cariboo Island. Quesnel Lake data collected in 2003 (UBC and BC MoE data) and reported previously by MPMC (2009), were not included because sample location coordinates and documented quality assurance and quality control (QA/QC) procedures were not available, only total metals were reported without dissolved metal concentrations, and method detection limits for most metals were elevated above BC WQGs.

The surface water quality stations identified to define pre-event water quality conditions are listed in Table 3-1 and illustrated in Figure 2.

Table 3-1: Summary of Surface Water Quality Stations Identified to Define Pre-Event Conditions

Area	Monitoring Station	Station Description	Number of Samples	Date Range	Data Source
Polley Lake	P1	North end of Polley Lake	84 (and 40 depth profiles)	1995 to 2014	MPMC
	P2	South end of Polley Lake	82 (and 42 depth profiles)	1995 to 2014	
Hazeltine Creek	W7	Upper Hazeltine Creek	266	1990 to 2014	MPMC
Edney Creek	W11	Downstream of confluence with Hazeltine Creek	67	1995 to 2014	MPMC
Quesnel Lake	E256574	Horsefly Bay	28	2004 to 2006	BC MoE
	E256575	Horsefly Bay	37		
	E256576	Horsefly Bay	37		
	E256577	Horsefly Bay	36		
	E256578	Horsefly Bay	36		
	E256579	Near Cariboo Island	35		
	E256580	West of Cariboo Island	33		
	E256582	West of Cariboo Island	34		
	E256583	East of Cariboo Island	33		
	E256584	East of Cariboo Island	4		
	E256585	East of Cariboo Island	4		
	E256586	East of Cariboo Island	34		
Quesnel River - near lake outlet	600034	At town of Likely	35	1972 to 1988	BC MoE
	E206117	Downstream of Likely	8	1985 to 1987	
Quesnel River -downstream	Gravelle Ferry Bridge	50 km downstream of Likely, towards Fraser River	6	2011 to 2014	BC MoE

3.1.2 Data Analysis

Pre-event water quality data received from MPMC and BC MoE were summarized and used in the screening approach to identify COPCs for the WQIA. The data were grouped into four areas: Hazeltine Creek, Polley Lake, Quesnel Lake, and Quesnel River. The data were received from sources with established QA/QC programs and were considered reliable for the purpose of defining baseline conditions for the impact assessment. Field quality control samples (e.g., field duplicates) were removed from the dataset and the following summary statistics were calculated for each area:

- total number of samples;
- number and percentage of samples with values below the method detection limit (MDL); and,
- minimum, maximum, median, mean, standard deviation (SD), standard error (SE), and 95th percentile concentrations.

For values that were reported as less than the MDL, one-half the MDL was substituted for calculation of mean, SD, SE, and 95th percentile. For parameters with greater than 50% non-detect values, mean, SD, and SE were not calculated. For parameters with greater than 95% non-detect values, 95th percentile was not calculated.

The summary statistics for each study area are presented in Appendix A. The 95th percentile was used to define baseline conditions in the post-event COPC screening (Section 3.3).

3.2 Post-Event Surface Water Quality

3.2.1 Data Collection

After the event, MPMC[4] initiated a water quality monitoring program in Polley Lake, Hazeltine Creek, Edney Creek, Quesnel Lake, and Quesnel River. The program was adapted based on factors that included, but were not limited to: monitoring results, safety and logistical constraints, recommendations from BC MoE, and seasonal conditions (e.g., lake turnover, onset of winter). A summary of the monitoring program, locations of all sampling stations, and reports on the field methods, data management, and data quality review are presented in Appendix B. An overview of the program, as it occurred from August 6, 2014, to February 28, 2015, is presented below.

The monitoring program had several components, including the following:

- delineation and tracking of the suspended solids plume in Quesnel Lake;
- monitoring at key locations in Polley Lake, Hazeltine Creek, Quesnel Lake, and Quesnel River;
- monitoring associated with movement of Polley Lake water around the “plug” at the south end of Polley Lake and into Hazeltine Creek;
- residential drinking water monitoring; and,
- sampling for an acute and chronic toxicity testing program.

[4] The post-evetn water quality monitoring program was developed by a team at MPMC that included a water quality specialist and environmental scientist.

Water quality monitoring was undertaken at a large number of stations at varying frequencies (Table 3-2 and Table 3-3; Figure 3). In the lakes, samples were collected at surface and throughout the water column. Stations sampled more than four times between August and February were termed 'routine stations' for the purpose of the WQIA and reflect stations where monitoring was undertaken at an implied frequency. Following the event, sampling was undertaken daily or every two days at first with a transition to approximately weekly in the months that followed[5] (Table 3-2; Figure 3). A number of other stations were sampled between one and four times from August to February, largely in Quesnel Lake, for the purposes of tracking the suspended solids plume and monitoring of residential drinking water quality. These stations were termed 'investigative stations' for the purpose of the WQIA because monitoring was undertaken infrequently for a specific purpose that did not require frequent sampling at one location (Table 3-3; Figure 3).

Water samples were analysed for a broad suite of parameters, including total and dissolved metals (limited dataset for mercury), anions, nutrients, and other water quality parameters[6]. Depth profiles of field parameters (i.e., pH, temperature, specific conductivity, DO, and turbidity) were conducted throughout the water column at stations in Polley Lake and Quesnel Lake. At some stations in Hazeltine Creek and Quesnel River, continuous data loggers were installed to record field parameter measurements (Table 3-2).

Seven routine stations were sampled in Polley Lake. Immediately after the event, boat access to Polley Lake was not permitted for safety reasons and sampling was limited to shoreline stations (POL-2, POL-3, and POL-4). In early September, sampling began at four stations located down the midline of the lake (P1, P2, POL-5, and POL-6) and continued until mid-November. Sampling was reduced going into winter because of limited safe access to the lake. Unseasonably warm winter conditions did not allow typical formation of ice on the lake, and as a result planned under-ice sampling was not carried out.

For safety reasons, monitoring of Hazeltine Creek did not commence until late August, when Polley Lake water levels were reduced to a safe level (in accordance with potential geotechnical risks associated with the "plug") and a safety protocol was in place for accessing the creek. One routine station was sampled in upper Hazeltine Creek (HAC-05) and two routine stations were sampled in lower Hazeltine Creek (HAC-01, HAC-08). Samples collected at HAC-01, HAC-01a, HAC-01b in lower Hazeltine Creek have contiguous sampling periods and are considered to represent the same location, as the sample point was moved slightly to adapt to changes in the creek channel due to rehabilitation activities and construction of sedimentation ponds. Continuous data loggers were deployed at two stations in Hazeltine Creek and removed according to winter conditions. Two routine monitoring stations were established in Edney Creek in February 2015 once its flow was diverted from the sedimentation ponds into a reconstructed lower Edney Creek channel. A data logger was deployed again in lower Hazeltine Creek in January 2015.

There were a total of 27 routine stations in Quesnel Lake. Immediately after the event, routine monitoring at key near-field and downstream stations commenced in addition to investigative monitoring for plume delineation. By late August, a routine monitoring program was implemented for the West Basin. Stations were added east of Cariboo Island in mid-September as the plume migrated east towards the main body of the lake during seiche events. As the onset of winter conditions made safe boat access to stations less reliable, the monitoring program was modified in late October in an effort to maintain spatial coverage and frequent monitoring of key locations for fall turnover. The program was maintained through turnover until mid-December 2014.

[5] Winter water quality sampling frequency also considered safety and accessibility related to weather or ice cover.

[6] Conductivity, turbidity, hardness, TDS, TSS, temperature, dissolved oxygen, pH.

One routine station (QUR-1) was established on Quesnel River at the Quesnel River Research Centre near the town of Likely on August 6, 2014, and was monitored daily until December 23, 2014. This station was a key location to monitor water flowing out of Quesnel Lake to the downstream environments. In addition to daily grab samples, an automatic sampler was installed that collected water three times per day for analysis of metals, anions, and turbidity. Removal of the automatic sampler was necessary with the onset of winter conditions. A sonde instrument was also installed to measure field parameters (i.e., pH, temperature, specific conductivity, DO, and turbidity) every 15 minutes. This instrument remains in place to the present day.

Investigative stations were located in most study areas (Table 3-3), and were sampled less frequently for specific purposes (e.g., delineation of the suspended solids plume). A residential drinking water monitoring program was initiated in response to source water concerns for residents that draw drinking water from Quesnel Lake and Quesnel River and included sampling near residential water intakes.

Table 3-2: Post-Event Routine Water Quality Monitoring Stations (August 2014 to February 2015)

Area	Station Name	Number of Surface Samples	Number of Samples at Depth	Sample Depth Range	Number of Profiles	Date Range (mm/dd/yyyy)

3.2.2 Data Compilation and Analysis

SNC-Lavalin Inc. (SNC-Lavalin) was retained by MPMC to assist with the development and implementation of a QA/QC program for the water quality monitoring program implemented immediately after the event. On December 20, 2014, program oversight and data management for the water quality monitoring program transitioned to MPMC from SNC-Lavalin. A summary of the program and relevant reports on the field methods, data management, and data quality review are presented in Appendix B.

The water quality monitoring data were evaluated by SNC-Lavalin and MPMC for quality and usefulness in accordance with the BC Field Sampling Manual (BC MWLAP 2003). Analytical and field monitoring data that were verified to be reliable, as well as station location information, were uploaded by MPMC to their water quality database. MPMC provided outputs of the data from August 2014 to February 2015 in an electronic format for this WQIA. The data were used as received and considered reliable for the purposes of the impact assessment because there was a process of sample continuity and data quality verification. The data were grouped into four areas, corresponding to samples that represent water quality conditions within Polley Lake, Hazeltine Creek, Quesnel Lake, and Quesnel River. For the purpose of the impact assessment, all remediation areas along Hazeltine Creek were combined and evaluated as one area.

Post-event water quality data compiled for all stations within an area were evaluated as one dataset for COPC screening (Section 3.3). Subsequent data analysis of COPC temporal trends focused on representative stations selected for each area. Substitutions were not made for values that were reported as less than the MDL and these values were set equal to the MDL for purposes of plotting data, calculating 30-day (d) averages, and correlation analysis. For field parameters, daily averages were calculated from continuous data loggers and averages at 1-m depth intervals were calculated for high-resolution depth profiles. Data from stations HAC-01, HAC-01a, HAC-01b were combined for station-specific water quality analyses as the data were considered to represent one sample location because of their close proximity and contiguous datasets.

3.3 Identification of COPCs: Hazeltine Creek and Receiving Environment

The total number of parameters or substances considered in the WQIA was 76, including physical parameters (specific conductivity, DO, hardness, pH, total dissolved solids, total suspended solids, turbidity, and water temperature), major ions (alkalinity, chloride, fluoride, sulphate), nutrients (ammonia, nitrate, nitrite, total nitrogen, total phosphorus), and total and dissolved metals (Appendix C, Table C-1). The purpose of the COPC screening process outlined below is to focus the post-event assessment on those substances that might be of consequence, thereby carrying out a more focused and detailed evaluation of post-event impact on water quality.

COPCs were identified from the post-event dataset for further characterization of post-event water quality at representative monitoring stations in Hazeltine Creek and the receiving environment. Substances were identified as COPCs if they were greater than pre-event concentrations and applicable BC WQGs based on the most sensitive receiving environment water use.

3.3.1 Receiving Environment Water Uses

Known environmental uses on Quesnel Lake, particularly with respect to the West Basin, were identified to determine the most sensitive water use for the receiving environment. The following environmental uses were identified for Quesnel Lake:

- Commercial, recreational, and aboriginal (CRA) fisheries;

- Recreational uses such as scenery and wildlife viewing, swimming, boating, kayaking, canoeing, waterskiing/tubing/wakeboarding, and in the winter snowmobiling and ice fishing when ice conditions allow; and,
- Drinking and residential water use for domestic purposes[7].

Although agriculture, especially cattle ranching, is an economic driver in the local area (Cariboo Envirotech 2009), there are no water licenses (current or pending) for stock watering or irrigation use for Quesnel Lake (BC MoE 2015b).

Water quality guidelines have been developed by BC MoE to be protective of different water uses, including aquatic life, wildlife, drinking water sources, recreational contact, and agriculture. Based on the above uses identified for Quesnel Lake, guidelines protective of aquatic life, wildlife, drinking water sources and recreational contact are applicable to the receiving environment in Quesnel Lake.

With the exception of molybdenum, total aluminum, and pH, the most sensitive receiving environment use was the protection of aquatic life. For molybdenum, the most conservative 30-d BC WQG value was adopted (i.e., irrigation assuming the copper: molybdenum ratio is less than 2:1 *in lieu* of a 30-d value for wildlife). For total aluminum, the most conservative maximum BC WQG was adopted (i.e., water for wildlife) because aquatic life guidelines are based only on dissolved aluminum. Recreational guidelines are not shown in Table 3-4; they are similar to, but in some cases less stringent than, drinking water guidelines and are thus implicitly considered in the analysis; however, recreational use is clearly a relevant receiving environment use. For pH, the drinking water guideline range of 6.5-8.5 was adopted that is slightly narrower than that specified for aquatic life.

Table 3-4: BC Water Quality Guidelines for Receiving Environment Uses Relevant to the Water Quality Impact Assessment

Parameter	Units	Maximum BC Water Quality Guidelines			Chronic BC Water Quality Guidelines	
		Aquatic Life	Drinking Water	Wildlife Water	Aquatic Life	Wildlife Water

Notes:
Values are taken from the approved guidelines unless otherwise noted
W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage
Hardness dependent guidelines are based on hardness of 50 mg/L, considered representative of average conditions in the receiving environment
Bold Indicates most conservative WQG
(a) up to 4 - highly sensitive to acid inputs; 4 to 8 - moderately sensitive; over 8 - low sensitivity
(b) hardness dependent sulphate guideline: BC 30-d WQG (mg/L) = 128 at hardness <30 mg/L, at hardness 31-75 mg/L = 218, at hardness 76-180 mg/L = 309, at hardness 181-250 mg/L = 429, at hardness >250 mg/L determine base on site water
(c) pH and temperature dependent ammonia guideline: values selected from Table 3 (maximum WQG) and Table 4 (30-d WQG) in BC WQG based on a temperature of 10°C and 7.0 pH, considered representative of average conditions in the receiving environment
(d) chloride dependent nitrite guideline: BC Max WQG (mg/L) = 0.06 at Cl <2 mg/L, at Cl 2-4 mg/L = 0.12, at Cl 4-6 mg/L = 0.18, at Cl 6-8 mg/L = 0.24, at Cl 8-10 = 0.30, at Cl >10 = 0.6; BC 30-d WQG (mg/L) = 0.02 mg/L at Cl <2 mg/L, at Cl 2-4 mg/l = 0.04, at Cl 4-6 mg/L = 0.06, at Cl 6-8 mg/L = 0.08, at Cl 8-10 mg/L = 0.1, at Cl >10 = 0.2, determined based on Cl <2 mg/L considered representative of average conditions in the receiving environment
(e) guideline is for chromium VI (Cr(VI))
(f) hardness dependent copper guideline: BC Max WQG (mg/L) = (0.094(hardness)+2)/1000; BC 30-d WQG (mg/L) = 0.002 at hardness ≤50 mg/L , at hardness >50 mg/L = 0.04*hardness/1000
(g) hardness dependent manganese guideline: BC Max WQG (mg/L) = 0.01102*(hardness)+0.54; BC 30-d WQG (mg/L) = 0.0044*hardness+0.605
(h) BC 30-d WQG for irrigation water for forage crops (most sensitive WQG) substituted due to concern for ruminants and no 30-d WQG proposed for wildlife water supply
(i) hardness dependent silver guideline: BC Max WQG (mg/L) = 0.0001 at hardness ≤100 mg/L, at hardness >100 mg/L = 0.003; BC 30-d WQG (mg/L) = 0.00005 at hardness ≤100 mg/L, at hardness > 100 mg/L = 0.0015
(j) hardness dependent zinc guideline: BC Max WQG (mg/L) = (33+0.75(hardness-90))/1000; BC 30-d WQG (mg/L) = (7.5+0.75(hardness-90))/1000
(k) pH dependent dissolved aluminum guideline: BC Max WQG (mg/L) = 0.1 at pH ≥6.5, at pH <6.5 = exp(1.209-2.426*(pH)+0.286*(pH^2)); BC 30-d WQG (mg/L) = 0.05 at pH ≥6.5, at pH <6.5 = exp(1.6-3.327*(median pH)+0.402*(median pH^2), determined based on 7.0 pH
(l) hardness dependent dissolved cadmium guideline: BC MaxWQG (mg/L) = (exp(1.03*ln(hardness)-5.274))/1000; BC 30-d WQG (mg/L) = (exp(0.736*ln(hardness)-4.943))/1000

3.3.2 COPC Identification

Post-event maximum and 95th percentile parameter concentrations calculated for Hazeltine Creek and each receiving environment area were compared to BC WQGs for the most sensitive water use identified in Table 3-4. Maximum and 95th percentile concentrations represented upper limit concentrations in the post-event water quality dataset. Water quality parameters were not identified as COPCs for Hazeltine Creek or the receiving environment areas if post-event upper limit concentrations were below the applicable guideline. BC WQGs are conservative environmental quality benchmarks with built-in safety factors that represent concentrations where adverse impacts on water quality are not expected. A parameter was identified to be of concern if maximum and 95th percentile concentrations were above the lowest applicable BC WQG. The potential for adverse effects on aquatic life and other receiving environment uses was evaluated in the impact assessment for parameters identified as COPCs.

With respect to parameters that do not have applicable BC WQGs, these parameters were identified to be of concern if post-event upper-limit concentrations were more than 20% higher than comparable pre-event concentrations. A difference of less than or equal to 20% between comparable post-event concentrations and pre-event concentrations was not considered to be distinguishable from the background conditions and therefore not considered to represent a potential effect to water quality in the receiving environment. This assessment criterion is consistent with BC MoE (2013) where a relative percent difference less than 20% between two duplicate water quality values is not considered to indicate a distinguishable difference between the two values.

Parameters that did not have a BC WQG and where a pre-event condition could not be defined (i.e., Quesnel Lake), were conservatively identified as COPCs.

Additional considerations in the identification of COPCs are listed below.

- Alkalinity, hardness, calcium, magnesium, potassium and sodium are components of TDS mixtures and so were not evaluated individually. Instead TDS was identified as a COPC because predicted concentrations were higher than baseline (+20%) and so were distinguishable from the baseline conditions. However, TDS benchmarks have been established in Northwest Territories (Diavik Diamond Mine), Alaska and Iowa (from 500 to 1000 mg/L) (ADEC 2009, IDNR 2009, WLWB 2013). Post-event 95th percentile TDS concentrations for Hazeltine Creek (460 mg/L), Quesnel Lake (101 mg/L) and Polley Lake (219 mg/L) were below these TDS benchmarks. Furthermore, upper bound concentrations in TDS constituents, sulphate and chloride, were below the BC WQG for the protection of aquatic life in Hazeltine Creek and the receiving environment areas.
- Tin was not identified as a COPC because it is the organic form of tin that is toxicologically relevant, not the inorganic form.
- Strontium was not identified as a COPC because 95th percentile concentrations in Hazeltine Creek and the receiving environment were substantially below the strontium chronic effects benchmark of 10.7 mg/L recently proposed by McPherson et al. (2014) for freshwater environments.
- Pre-event upper-limit concentrations of total chromium and zinc in Quesnel River were above the applicable BC WQG and post-event concentrations were indistinguishable from comparable pre-event concentrations (less than a 20% difference). Total chromium and zinc were therefore not identified as COPCs for Quesnel River.Mercury was not identified as a COPC in the receiving environment because measured values above the BC WQG were rarely reported. Detection limits in some cases (<0.00001, <0.00005) were equal to or

greater than the WQG and this uncertainty should be addressed by future monitoring of waterborne mercury in the receiving environment at detection limits below the BC WQG. Measurement of mercury in water is a relatively poor indicator of mercury toxicity. As a bioaccumulative constituent, the toxic effects of mercury are best evaluated through a comparison of aquatic organism tissues to tissue-based toxicological benchmarks or guidelines. With respect to Quesnel Lake, mercury concentrations in fish tissues sampled after the event will be addressed in the future Human Health Ecological Risk Assessment.

- Vanadium was not identified as a COPC in the receiving environment because concentrations were below the lowest chronic toxicity value documented by Environment Canada and Health Canada (2010) (0.1 mg/L).
- Total phosphorus was retained as a COPC for Polley Lake and Quesnel Lake because the BC WQG directly applies to lake environments. In Quesnel River close to Likely, the upper bound post-event concentration was lower than the corresponding concentration before the event, indicating no contribution from the event. Further downstream at the Gravelle Ferry Bridge post-event concentrations in Quesnel River are also lower than concentrations measured prior to the event. A post-event assessment of total phosphorus was only relevant for the receiving environment, not Hazeltine Creek because the creek does not currently support substantial instream habitat including plants and algae whose growth could be affected by phosphorus concentrations in the water.

3.4 Impact Assessment Approach

3.4.1 Hazeltine Creek

3.4.1.1 COPC Assessment

At Station HAC-05[8] in the upper creek and Station HAC-01[9] in the lower creek, instantaneous measurements and rolling 30-d average values for each COPC were compared against the following applicable ambient BC WQGs to assess changes in water quality as a result of the event. Data collected between August 2014 and February 2015 were used in the assessment.

- Instantaneous measurements were compared against the short-term maximum BC WQGs (where available) for the most sensitive water use, to evaluate intermittent or transient impacts on water quality (BC MoE 2015a).
- Rolling 30-d average values were calculated and compared against long-term average BC WQGs. The 30-d mean guidelines are intended to be applied to mean concentrations of a minimum of five samples collected over a 30-d time period (BC MoE 2015a).

Temporal and spatial trends in the concentrations of each COPC were discussed with a focus on changes in concentrations related to the event.

[8] Station HAC-05 in upper Hazeltine Creek is downstream of the TSF at the Gavin Lake Road bridge.

[9] Station HAC-01 in lower Hazeltine Creek is at the outlet of Hazeltine and Edney creeks into Quesnel Lake. This station was moved to HAC-01a, then HAC-01b during construction of the sedimentation ponds just upstream of this location.

3.4.1.2 Supporting Environmental Parameters

Turbidity, DO, specific conductivity, and temperature data collected from August 2014 to February 2015 from station HAC-05 (upper Hazeltine Creek) and station HAC-01 (lower Hazeltine Creek) were plotted.

3.4.2 Receiving Environment

3.4.2.1 Selection of Representative Stations

Parameters identified as COPCs were evaluated further by examining temporal trends at representative monitoring stations in each of the three receiving environment areas (Figure 4 and Table 3-5). The time period for the evaluation of trends of metal and nutrient COPCs at these representative stations was extended to April 2015 as discussed in Section 2.2. The rationale for station selection is provided in the summaries by water body provided below.

Table 3-5: Summary of Representative Water Quality Stations for the Receiving Environment

Water Quality Study Area	Area #	Water Quality Monitoring Stations Selected as Representative Stations
Polley Lake	Area 3	P1, P2
Quesnel Lake	Area 8	QUL-2, QUL-66, QUL-66a, QUL-18, QUL-21
Quesnel Lake (turbidity only)	Area 8	QUL-120a, QUL-21a
Quesnel River	Area 9	QUR-1, Gravelle Ferry Bridge

TITLE
POST-EVENT REPRESENTATIVE WATER QUALITY STATIONS

PROJECT NO.	CONTROL	REV.	FIGURE
1411734	10000	A	4

IF THIS MEASUREMENT DOES NOT MATCH WHAT IS SHOWN, THE SHEET SIZE HAS BEEN MODIFIED FROM: ANSI B

Polley Lake

Two stations that represented the deepest areas of the lake, provided geographical coverage, and with the largest number of post-event water quality data, were selected from a possible seven routine stations sampled on Polley Lake:

- **Station P1** along the midline, at the north end of the lake.
- **Station P2** along the midline, at the south end of the lake.

Quesnel Lake

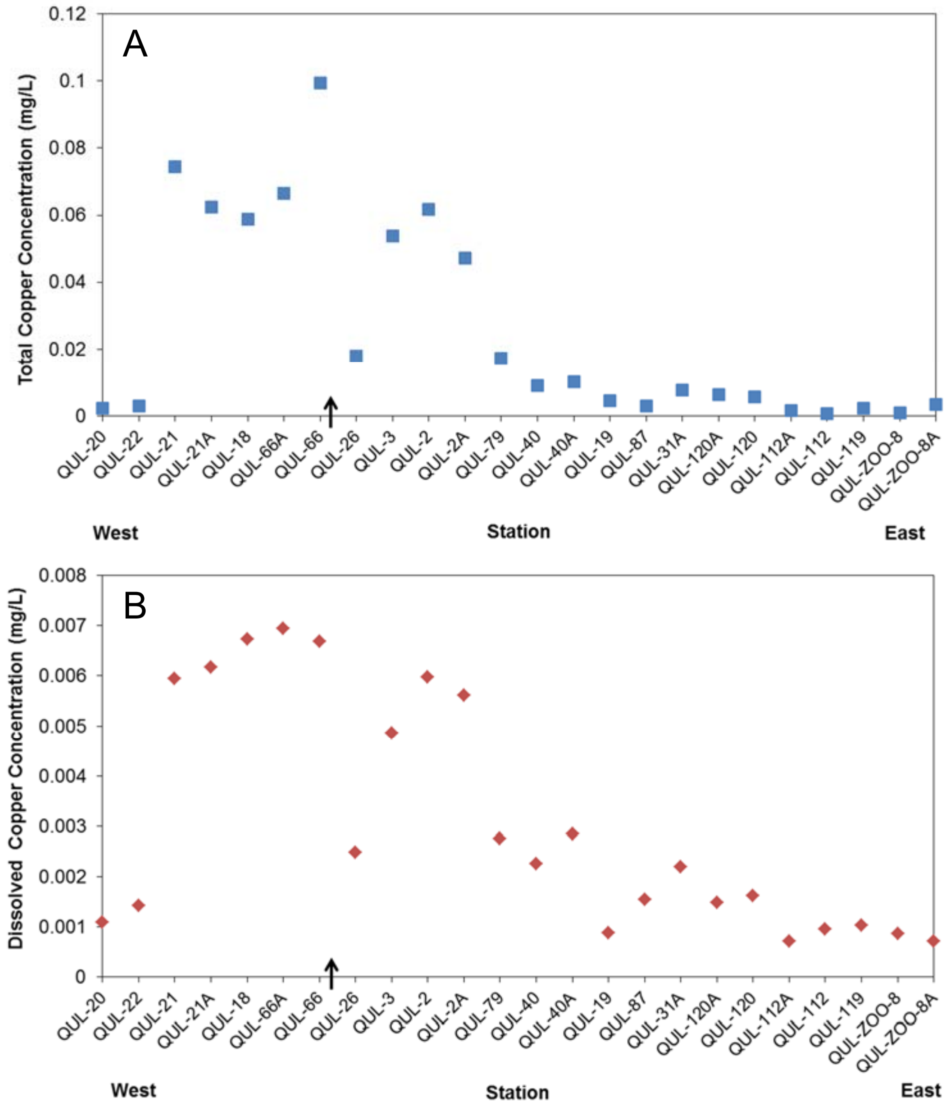
Five stations on Quesnel Lake were selected from a possible 27 routine stations sampled, to provide spatial representation across the West Basin relevant to the event, based on the following considerations:

- The location of the monitoring stations relative to event-related inputs via Hazeltine Creek. Stations representative of near-field (close to Hazeltine Creek), mid-field (some distance from Hazeltine Creek) and far-field areas (located closer to Likely [west] and Cariboo Island [east]) were targeted for assessment.
- Specific stations were selected from examination of post-event 95^{th} percentile values calculated for copper and turbidity at depth (below 20 m) at 24 routine stations on Quesnel Lake (Figure 5 and Figure 6). Copper data at depth were used to select representative stations because it was the only metal where both total and dissolved forms were identified as COPCs in Quesnel Lake and concentrations were higher at depth (see Section 4.2). Stations with higher reported copper concentrations and turbidity levels for that area of the lake (as indicated by 95^{th} percentile values) were typically selected to represent a conservative assessment of water quality over time.
- The number of measurements available for each station relative to the other routine stations.

The locations of each representative station selected for assessment are described as follows:

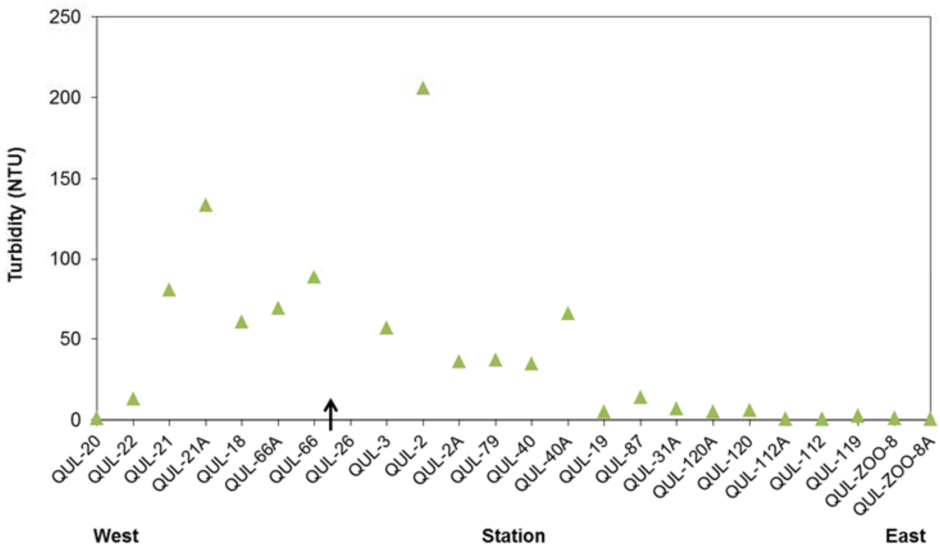
- **Station QUL-66** is located near the mouth of Hazeltine Creek where the debris flow entered the lake. Stations QUL-54, -55, and -56 replaced Station QUL-66 in March 2015 to adapt to the new outlet location of Hazeltine Creek into Quesnel Lake, downstream of the sedimentation ponds.
- **Station QUL-66a** is a deep station north of QUL-66, but still close to the mouth of Hazeltine Creek.
- **Station QUL-18** is located northwest towards Quesnel River between QUL-66 and QUL-21, and represents one of the deepest points in the West Basin. It was assessed with regards to chemical COPCs because monitoring at this station extended to April 2015.
- **Station QUL-21** is located further northwest towards Quesnel River. QUL-21a is the corresponding deep station south of QUL-21 and was only assessed with regards to turbidity measures of the plume in 2014.
- **Station QUL-2** is located east of the mouth of Hazeltine Creek towards Cariboo Island. Data were pooled with Station QUL-2a (a nearby deep station) with regards to time series for turbidity and chemical COPCs because monitoring at this latter station extended to April 2015.

- **Station QUL-120a** is a deep far-field station located east of Cariboo Island towards the main body of the lake and was assessed with regards to turbidity measures of the plume. Data were pooled with Station QUL-120 with regards to time series of phosphorus to provide a more comprehensive dataset.



Note: Arrow represents the inflow from Hazeltine Creek and Tailings Dam Failure event-related inputs to the West Basin of Quesnel Lake.

Figure 5: Total (A) and Dissolved (B) Copper Concentrations (95th Percentile) at Depth (below 20 m) at 24 Routine Stations on Quesnel Lake (data from August 2014 to February 2015). The highest concentrations were typically measured at depth.



Note: Arrow represents the inflow from Hazeltine Creek and Tailings Dam Failure event related inputs to the West Basin of Quesnel Lake

Figure 6: Turbidity Levels (95th Percentile) at Depth (below 20 m) at 24 Routine Stations on Quesnel Lake (data from August 2014 to February 2015). The highest concentrations were typically measured at depth.

Quesnel River

Two stations on Quesnel River were selected as representative stations; one station close to the outlet of Quesnel Lake and one station 50 km downstream of Likely:

- **Station QUR-1** is located at the Quesnel River Research Centre near the town of Likely and reflects water quality at the outflow of Quesnel Lake. This station was routinely monitored by MPMC during the post-event period.
- **A station at the Gravelle Ferry Bridge**, which is more than 50 km downstream of Likely, was monitored by BC MoE prior to the event (June 2011, 2012, and 2014 and July 2014) and more frequently post-event (August 2014 to March 2015). Approximately 50 water samples were collected in the post-event period for metals concentrations, major ions, nutrients, turbidity, and general physical parameters. Measurement of TSS and TDS were limited to six sampling events. Water quality data from this location were not used for the identification of COPCs for Quesnel River, but were relied upon for discussion of downstream water quality because of the limited number of samples collected from the Quesnel River between the Gravelle Ferry Bridge and Station QUR-1 at Likely.

3.4.2.2 COPC Assessment

Instantaneous measurements and rolling 30-d average values for each COPC were compared against the following applicable ambient BC WQGs to assess changes in water quality as a result of the event.

- Instantaneous measurements were compared against the short-term maximum BC WQGs (where available) for the most sensitive water use to evaluate intermittent or transient impacts on aquatic life.

- Rolling 30-d average values were calculated and compared against long-term average BC WQGs that are intended to prevent sub-lethal and lethal effects on the most sensitive species and life stage for an indefinite time period. The 30-d mean guidelines are intended to be applied to mean concentrations of a minimum of five samples collected over a 30-d time period (BC MoE 2015a).

Temporal and spatial trends in the concentrations of each COPC were discussed with a focus on changes in concentrations related to the event.

3.4.2.3 Supporting Environmental Parameters

Water quality profiles of turbidity, DO, specific conductivity, and temperature were plotted for representative stations in Quesnel Lake and Polley Lake. Water quality measurements taken at Station QUR-1 on the Quesnel River were plotted.

4.0 IMPACT ASSESSMENT

4.1 Hazeltine Creek

Hazeltine Creek located directly downstream of the TSF was the study area most directly impacted by the event. As a result of the physical impacts on Hazeltine Creek, the creek was not considered to be fish habitat during the post-event assessment study period. Even though this creek is currently not significantly utilized by aquatic organisms, aquatic habitat use is an intended future use in the longer term; therefore, water quality was assessed based on comparisons to WQGs that imply an aquatic habitat use.

Post-event TSS and turbidity levels in Hazeltine Creek were elevated and varied widely by one to three orders of magnitude (Section 4.1.2 and Appendices D and E). Turbid and high suspended sediment conditions inevitably meant that 21 metals in total form were identified as COPCs (Table 4-1). Six of these 22 metals were also identified as COPCs in their dissolved forms.

Table 4-1: Contaminants of Potential Concern Identified in Hazeltine Creek

Study Area	Non-Chemical Substances	Total Metals	Dissolved Metals
Hazeltine Creek (#4-7)	**particulate matter (turbidity, TSS)**	**aluminum**, arsenic, barium, beryllium, cadmium, **chromium**, cobalt, **copper**, **iron**, lead, lithium, manganese, mercury, **molybdenum**, nickel, **selenium**, silver, thallium, titanium, vanadium, zinc	**aluminum, chromium, copper, iron, molybdenum, selenium**

Notes:
TSS = total suspended solids; TP = total phosphorus; TDS = total dissolved solids
Bolded COPCs were evaluated in the Water Quality Impact Assessment
Dissolved oxygen was above the minimum requirements for aquatic life
In-situ pH was within the BC WQG range of 6.5 to 9.0 for aquatic life

Changes in water quality described here in the WQIA relate to the COPCs aluminum, chromium, copper, iron, molybdenum, and selenium. Both total and dissolved forms of these COPCs were elevated in Hazeltine Creek following the event. Post-event concentrations of the other 15 metals were identified as COPCs based on total metal concentrations that were associated with elevated loads of suspended sediment and particulates rapidly transported downstream to Quesnel Lake in the weeks immediately following the event. An assessment of the potential impact of the downstream transport of particulate metals on aquatic life in Quesnel Lake is addressed in Section 4.2.2.3 of this WQIA as well as in the Quesnel and Polley Lakes Aquatic Productivity Impact Assessment (Golder 2015d).

- *WQIA Section 4.2.2.3:* Total and dissolved metal concentrations measured post-event in the Quesnel Lake and Quesnel River receiving environments were evaluated based on comparison to WQGs and pre-event concentrations.
- *Quesnel and Polley Lakes Aquatic Productivity Impact Assessment*: Both aqueous and dietary exposure routes for metal COPCs identified in the WQIA were evaluated further with respect to potential impacts on aquatic life.

4.1.1 Field Measured Environmental Parameters

Post-event temperature changes in Hazeltine Creek reflected typical seasonal patterns and DO was above the minimum requirements for aquatic life during all sampling events from August 2014 through February 2015 (Appendix D, Section 2.0). Turbidity is discussed with suspended particulate matter in Section 4.1.2.

4.1.2 Suspended Particulate Matter

In both upper and lower Hazeltine Creek, turbidity fluctuated by two- to three orders of magnitude, respectively, with no apparent temporal trends. Ongoing, active erosion of exposed banks has been noted in parts of the creek and examples are highlighted in Figure 7. Additionally, construction activities related to bank stabilization, erosion control, and rehabilitation have been undertaken in various parts of the creek. Sedimentation ponds constructed in lower Hazeltine Creek and commissioned on December 12, 2014, have reduced turbidity in the outflow to Quesnel Lake; however, these ponds are not capable of removing very fine particulate material (MPMC unpublished data). Golder investigated the possibility of using flocculants to enhance particulate removal efficiency of the sedimentation ponds (Golder 2015b), but it was determined that while flocculants are a proven technology in closed, engineered systems, they would be of limited efficacy in that specific application. Further details are provided in Golder (2015b).

Figure 7: Photographs of erosion along Hazeltine Creek post-event.

Available post-event data indicate that TSS and turbidity in both upper and lower Hazeltine Creek did increase as a result of the event, and that post-event concentrations were above BC WQGs. The magnitude of observed exceedances was more prominent in the lower creek compared to the upper creek prior to sedimentation pond commissioning in December 2014. Since then, the magnitude of guideline exceedance in the lower creek has been smaller than the upper creek.

- In upper Hazeltine Creek (HAC-05), TSS and turbidity varied by two or more orders of magnitude during the post-event period and were higher than the corresponding 24-h BC WQGs, at times considerably so. The 30-d average concentrations of these parameters were consistently above the 30-d BC WQG, with turbidity and TSS showing different patterns over time (Appendix D: Section 2.0, Appendix E: Section 2.1).
- In lower Hazeltine Creek (HAC-01), both TSS and turbidity were above the 24-h and 30-d average BC WQGs (Appendix D: Section 2.0, Appendix E: Section 2.1). Both parameters decreased over time, although turbidity was more variable. Concentrations of both turbidity and TSS were reduced by approximately two orders of magnitude after the sedimentation ponds in this lower section were commissioned in December 2014.

TSS and turbidity in Hazeltine Creek are expected to improve as the creek channel erosion control work is extended to the canyon. The data included in this report extend to February; however, considerable water quality improvements have been more recently observed as the channel was extended to the canyon and Hazeltine Creek water clarity being visibly improved (Figure 8). Detailed results from March 2015 onward will be provided in subsequent reports.

Figure 8. Hazeltine Creek turbidity has decreased since erosion control works, part of Hazeltine Creek channel rehabilitation, was completed on May 11, 2015.

4.1.3 Metals

Copper

Total copper concentrations in Hazeltine Creek were above BC WQGs for the protection of aquatic life following the event and post-event concentrations remained above BC WQGs in February 2015 (Appendix E: Section 2.2). The frequency and magnitude of exceedance was more prominent in the lower section of the creek compared to the upper creek.

The progressive decrease in total copper from peak concentrations in August was particularly evident in lower Hazeltine Creek. Concentrations decreased from several orders of magnitude above the BC WQG in the first three to four months following the event, to concentrations closer to the guideline after December 2014. Dissolved concentrations in lower Hazeltine Creek were more stable over the post-event period, with 30-d average concentrations consistently above the 30-d guideline and periodic exceedances of the maximum WQG (Appendix E: Section 2.2).

Aluminum

Total aluminum concentrations in upper and lower Hazeltine Creek were elevated by one to two orders of magnitude above the BC maximum wildlife WQG after the event, but decreased to below the guideline by December 2014 when the sediment ponds became operational (Appendix E: Section 2.3).

Dissolved concentrations were typically below BC WQGs for the protection of aquatic life in the upper creek and were above these guidelines in the lower creek (Appendix E: Section 2.3). In the lower creek dissolved concentrations periodically exceeded the maximum BC WQG throughout the post-event period, though a decrease in concentrations was evident in December through February when concentrations were lower than or approximated the maximum WQG (Appendix E: Section 2.3). Thirty-day rolling average concentrations calculated for the lower creek remained above the 30-d BC WQG for the duration of the post-event period until February 2015 (Appendix E: Section 2.3).

Chromium

Chromium is most commonly found in trivalent Cr(III) and hexavalent Cr(VI) states in freshwater environments. Cr(III) oxidizes slowly to Cr(VI), although Cr(VI) is more soluble (United States Environmental Protection Agency [US EPA] 1984). As such, Cr(III) dominates in reducing environments such as sediments and wetlands, whereas Cr(VI) is the primary species found in surface waters (CCME 1999). The hexavalent form is more toxic to aquatic life than the trivalent form, and thus is typically addressed separately in water quality guideline derivations. The 30-d working BC WQGs for chromium are 0.001 mg/L for Cr(VI) and 0.0089 mg/L for Cr(III) adopted from the federal chromium water quality guideline (CCME 1999).

Post-event, 30-d average total concentrations in Hazeltine Creek were above both Cr(VI) and Cr(III) guidelines, until January 2015, when total concentrations decreased below the Cr(III) WQG, but remained above the Cr(VI) WQG (Appendix E: Section 2.4). Dissolved 30-d average concentrations were typically below the lowest guideline. Speciation data available for lower Hazeltine Creek indicate a small proportion of the dissolved chromium was likely present in the more toxic Cr(VI) form. The Cr(III) WQG is therefore more applicable to the lower section of this creek (Appendix C, Table C-7). In January and February total concentrations were below the Cr(III) BC WQG.

Iron

Total iron concentrations in Hazeltine Creek were elevated by two to three orders of magnitude above the BC maximum WQG for the protection of aquatic life after the event, but decreased to below the guideline by December 2014 when the sediment ponds became operational (Appendix E: Section 2.5). In February total concentrations were above the BC WQG, but were within an order of magnitude of the guideline. Total iron concentrations are expected to reflect elevated suspended sediment conditions in the creek that are influenced by ongoing bank erosion because iron has a propensity to preferentially adsorb to particulates.

Dissolved concentrations in February were below the dissolved BC WQG in Hazeltine Creek. Between August and December 2014 the majority of dissolved iron concentrations were below the dissolved BC WQG with periodic guideline exceedances in the lower creek (Appendix E: Section 2.5).

Molybdenum

Total and dissolved molybdenum concentrations were below the most conservative maximum WQG for wildlife, but 30-d rolling average concentrations were above the most sensitive long term average WQG conservatively applied to address potential exposure to sensitive ruminant wildlife (Appendix E: Section 2.6). The most relevant exposure route for molybdenum uptake by wildlife ruminants, such as deer and moose, is through their plant-based diet rather than directly via drinking water (Swain 1986). Hazeltine Creek does not currently support within-stream vegetation, and riparian vegetation is presently limited; planting has only recently started. Thus, since the event, there has been no or limited potential for the uptake of molybdenum by ruminant wildlife. Sampling of vegetation in impacted areas is planned for the near future, as part of the risk assessment studies.

Selenium

Thirty-day rolling average concentrations of total selenium calculated for upper Hazeltine Creek from September to February were below the 30-d BC WQG. Corresponding average concentrations in the lower creek were above this guideline for a few weeks following the event (Appendix E: Section 2.7). By mid-October, total concentrations had decreased below the guideline and this decrease continued throughout the post-event period. The initial transient peak in total selenium lasted a few weeks and was not accompanied by dissolved concentrations that exceeded the BC WQG. The potential for selenium uptake by lower trophic levels following the event would have been further limited by the altered creek environment. After the event the creek had limited aquatic habitat to support lower trophic levels, no fish presence and a lack of breeding habitat for aquatic feeding birds.

4.1.4 Summary

Water quality in Hazeltine Creek has been influenced by the event, ongoing active erosion of exposed banks, and remediation activities in the creek. Sedimentation ponds constructed in lower Hazeltine Creek and commissioned December 12, 2014, had reduced suspended particulate matter in the lower creek. However, following termination of discharge from the TSF, completion of erosion control works was the primary strategy for addressing turbid water outflows from Hazeltine Creek (see photo Figure 8). Concentrations of metals associated with suspended materials, such as aluminum and iron, have also decreased substantially from peak concentrations in August. Dissolved concentrations of iron and aluminum were substantially lower than total concentrations. By the end of February, dissolved iron had decreased below the BC WQG, but dissolved aluminum was still above the 30-d WQG. Total and dissolved copper concentrations decreased substantially over the post-event period from peak concentrations in August, but were still above BC WQGs in February.

4.2 Receiving Environment

Polley Lake received direct inputs of TSF supernatant, tailings, and potentially some dam construction material from the event whereas Quesnel Lake received event-related inputs via Hazeltine Creek which included the above, as well as material eroded from the Hazeltine channel. Quesnel River represented the far-field receiving environment downstream from Quesnel Lake. Based on the COPC screening process described in Section 3.3, COPCs were identified for Polley Lake, Quesnel Lake, and Quesnel River (QUR-1; Table 4-2).

Table 4-2: Contaminants of Potential Concern Identified in the Receiving Environment

Study Area	Non-Chemical Substances	Total Metals	Dissolved Metals	Non-Metal Substances
Polley Lake (#3)	particulate matter (turbidity, TSS)	copper, molybdenum	molybdenum	TP
Quesnel Lake (#8)	particulate matter (turbidity, TSS)	chromium, copper, iron	copper	TP
Quesnel River (#9)	particulate matter (turbidity)	copper	copper	*no substances*

1) Notes:
2) TSS = total suspended solids; TP = total phosphorus; TDS = total dissolved solids.
3) Dissolved oxygen was above the minimum requirements for aquatic life in all areas except Polley Lake; this will be discussed under Section 4.2.2.1 – Supporting Environmental Parameters.
4) In-situ pH was within the BC WQG range of 6.5 to 8.5 (drinking water) with the exception of: 39% of samples in Polley Lake and <1% of samples in Quensel Lake and Quesnel River that exceeded WQG upper limit of 8.5
5) In-situ pH was within the BC WQG range of 6.5 to 9.0 (aquatic life) with the exception of 4% of samples in Polley Lake and <1% of samples in Quesnel River that exceeded WQG upper limit of 9.0.
6) Nitrite concentrations were below the maximum and 30-day BC WQGs at representative stations P1 (North) and P2 (South). Nitrate exceedances occurred in samples collected in September from POL-5 and POL-6. Subsequent samples collected from this station were below the BC WQG.

4.2.1 Relationship between Receiving Environment and Source Water Quality

A comparison of baseline water quality in the near-field receiving environment (i.e., Polley Lake and Quesnel Lake) to the pre-event TSF supernatant or source water was completed to identify which parameters could be expected to be elevated in the receiving environment as a result of the event and to corroborate the identification of COPCs.

Receiving environment water quality was represented by pre-event baseline data for Polley Lake (Appendix A, Table A-1) and post-event data from Quesnel Lake monitoring stations located east of Cariboo Island collected between August 2014 and February 2015. This Quesnel Lake dataset was used to represent baseline conditions because pre-event data from the West Basin and West Arm were insufficient to do so (i.e., no metals data). Samples with turbidity values above 1 NTU were excluded from this dataset as these could reflect flow of the turbid plume, trapped below the thermocline, that was transported eastward over the sill during seiche events in late summer 2014 (Tetra Tech 2015; Petticrew et al. 2015). Source water quality was based on data reported by SNC-Lavalin (2014) for the period from 2009 to 2014, where available, or from MPMC site monitoring. An enrichment factor, calculated as the ratio between a chemical concentration in source water and the receiving environment, was determined for chemical parameters identified as COPCs in Polley Lake and Quesnel Lake (Table 4-2), based on respective mean and maximum concentrations. An enrichment factor greater than 1 is therefore indicative of high concentrations in TSF water, relative to receiving waters. The enrichment factor is used here to indicate the relative potential for increases to the concentration of the receiving environment from the TSF supernatant; however, it does not indicate a numeric multiple of predicted concentration which would depend on a number of factors such as the size of the receiving environment. It also does not provide insight into potential for increased concentrations from eroded Hazeltine Creek material.

Enrichment factors for COPCs in TSF water compared to receiving waters are presented in Table 4-3 for Polley Lake and Quesnel Lake. These ratios range from less than 1, indicating that concentrations are lower in the TSF compared to the receiving environment (e.g., phosphorus in Polley Lake), to approximately 600 for dissolved copper (in Quesnel Lake). Enrichment factors for phosphorus and chromium are low, indicating that the TSF supernatant was not likely to be a major source of these COPCs. Pre-event conditions in Hazeltine Creek regularly exceeded BC WQGs for chromium. Copper, iron, and molybdenum have high enrichment factors, indicating that these COPCs may be mine related (i.e., from the TSF).

Table 4-3: Enrichment Factors of Contaminants of Potential Concern in Pre-event TSF Supernatant Relative to Polley Lake (Pre-event) and Quesnel Lake (Post-event) Water Quality

Parameter	Concentration (mg/L)						Enrichment Factor[b]			
	Polley Lake Pre-event (1995 - July 2014)		Quesnel Lake Post-event[a] (August 2014 - February 2015)		TSF supernatant (2009 - 2014)		Supernatant / Polley Lake		Supernatant / Quesnel Lake	
	Mean	Maximum	Mean	Maximum	Mean	Maximum	Based on Mean	Based on Maximum	Based on Mean	Based on Maximum
Total Phosphorus	0.041	0.34	<0.002	0.029	0.024	0.085	0.6	0.3	12	3.0
Total Chromium	<0.0005	<0.001	<0.0005	0.006	0.00054	0.0021	n/c	n/c	1.1	0.3
Total Copper	0.0023	0.032	<0.001	0.0042	0.014	0.064	7.2	6.0	14	15
Dissolved Copper	0.0018	0.010	0.00051	0.001	0.022	0.6	n/c	n/c	42	601
Total Iron	<0.03	0.13	<0.03	0.052	0.27	1.7	n/c	n/c	8.9	33
Total Molybdenum	0.0016	0.0025	0.0003	0.0018	0.21	0.2	128	84	n/c	n/c
Dissolved Molybdenum	0.0015	0.0023	0.0003	0.00048	0.13	0.28	86	122	n/c	n/c

Notes:
n/c: Enrichment factor not calculated for parameters not identified as contaminants of potential concern in a receiving environment.

(a) Based on post-event data from monitoring stations east of Cariboo Island with turbidity ≤1 NTU (i.e., to exclude samples possibly influenced by the turbidity plume)

(b) Enrichment factor = concentration in TSF supernatant / receiving environment

4.2.2 Changes in Receiving Environment Water Quality

In this section changes in suspended particulate matter, metals, and phosphorus are evaluated for representative stations within each study area. Temporal and spatial changes throughout the post-event period from August 2014 to April 2015 are discussed in relation to applicable BC WQGs.

4.2.2.1 Field Measured Environmental Parameters

Field water column profile measurements of DO, water temperature, turbidity, and specific conductivity in Polley Lake, Quesnel Lake, and Quesnel River are shown in Appendix D. This section summarizes changes in field profiles resulting from the event with a focus on changes in turbidity.

Polley Lake

In July 2014, prior to the event, Polley Lake was thermally stratified and the thermocline was located at a depth of 5 to 10 m, as is normal for Polley Lake. Surface water above the thermocline was well oxygenated (greater than [>] 9 mg/L) and DO decreased with depth to less than 5 mg/L at approximately 25 m deep. Specific conductivity was uniform throughout the water column. Thermal stratification of the lake was less pronounced post-event in that surface water was cooler post-event than pre-event, and deep water was warmer (i.e., the difference between surface and deep temperature was less post-event than pre-event). Dissolved oxygen was reduced to less than the minimum BC WQG of 5 mg/L at depths below 10 m. Turbidity and specific conductivity were elevated below 7 m, indicative of the suspended materials and TDS deposited in the lake from the event.

Turbidity at depth decreased over the late summer as particulate matter settled (Figure 9 and Figure 10). Specific conductivity remained unchanged during late summer. In mid-October, lake surface water began to cool further and mix with the deeper water and by late October temperature, DO, turbidity, and specific conductivity were uniform throughout the water column. By mid-November, DO increased to between 5 and 7 mg/L and turbidity decreased to less than 1 NTU. Sampling was discontinued from November 18 through to April 2015 (with the exception of one sample) due to the inability to safely access off-shore stations because of thin ice cover.

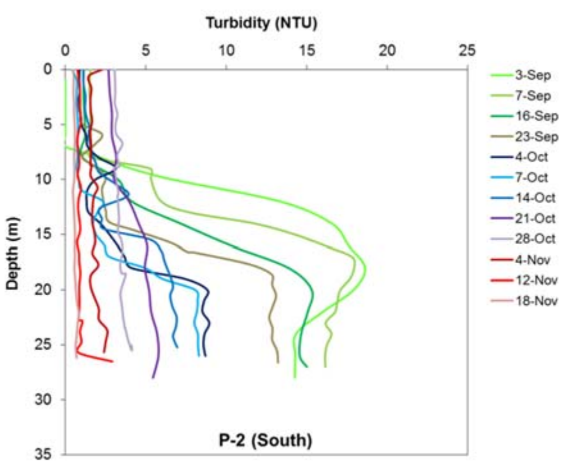


Figure 9: Post-event Depth Profiles of In-situ Measured Turbidity at Station P2, Polley Lake.

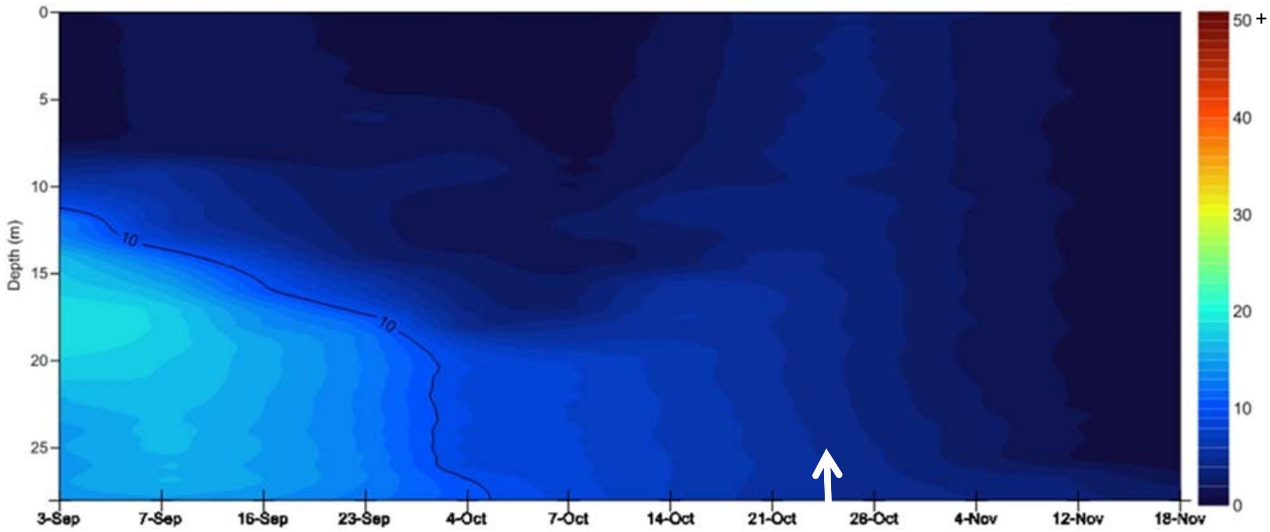

Note: The white arrow represents the approximate timing of late-October turnover in Polley Lake.

Figure 10: Post-event Contours of In-situ Measured Turbidity at Station P2, Polley Lake. Turbidity (NTU) shown on right hand axis.

Quesnel Lake

Post-event monitoring in the West Basin showed the lake to be thermally stratified with a thermocline located at depth between 10 to 25 m. Turbidity and conductivity were elevated below 30 m, indicative of the plume of suspended and dissolved materials deposited in the lake from the event that was trapped below the thermocline. Small peaks in turbidity between 20 and 50 m depths and to the east of Cariboo Island (e.g., QUL-120a, Appendix D; Section 3.0) reflect movement of deep turbid water over the sill (35 m depth) into the deeper main body of the lake. A decrease in turbidity at depth as particulate matter settled over the late summer was noted for some stations (e.g., QUL-66 close to Hazeltine Creek and QUL-18 in the West Basin towards the Quesnel River outflow; Figure 11 to Figure 13).

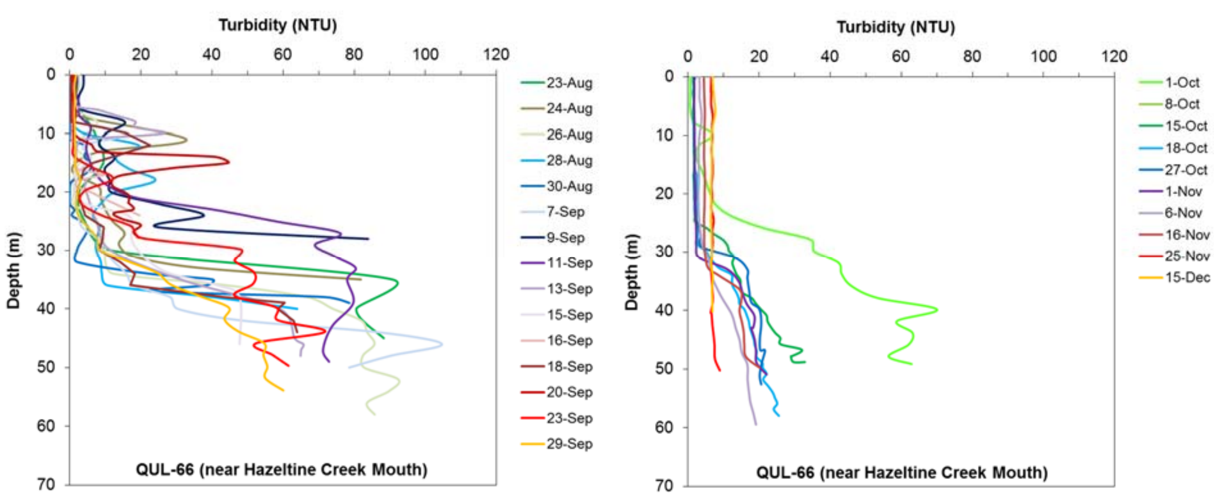

Figure 11: Post-event Depth Profiles of In-situ Measured Turbidity at Station QUL-66, Quesnel Lake.

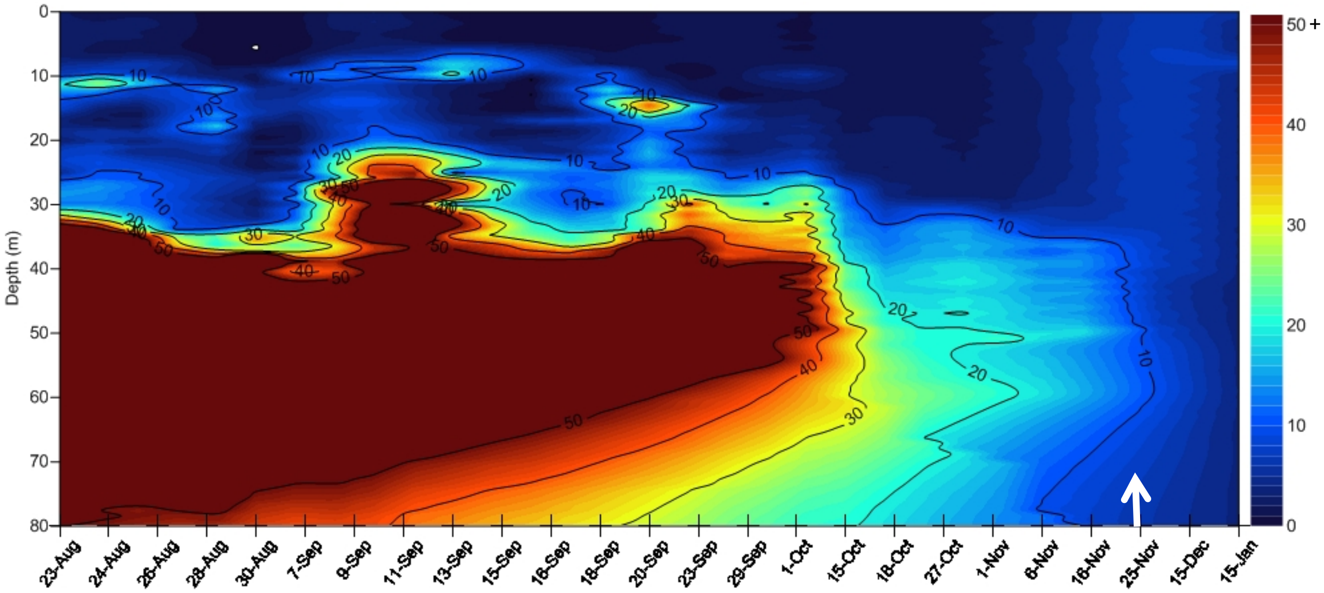
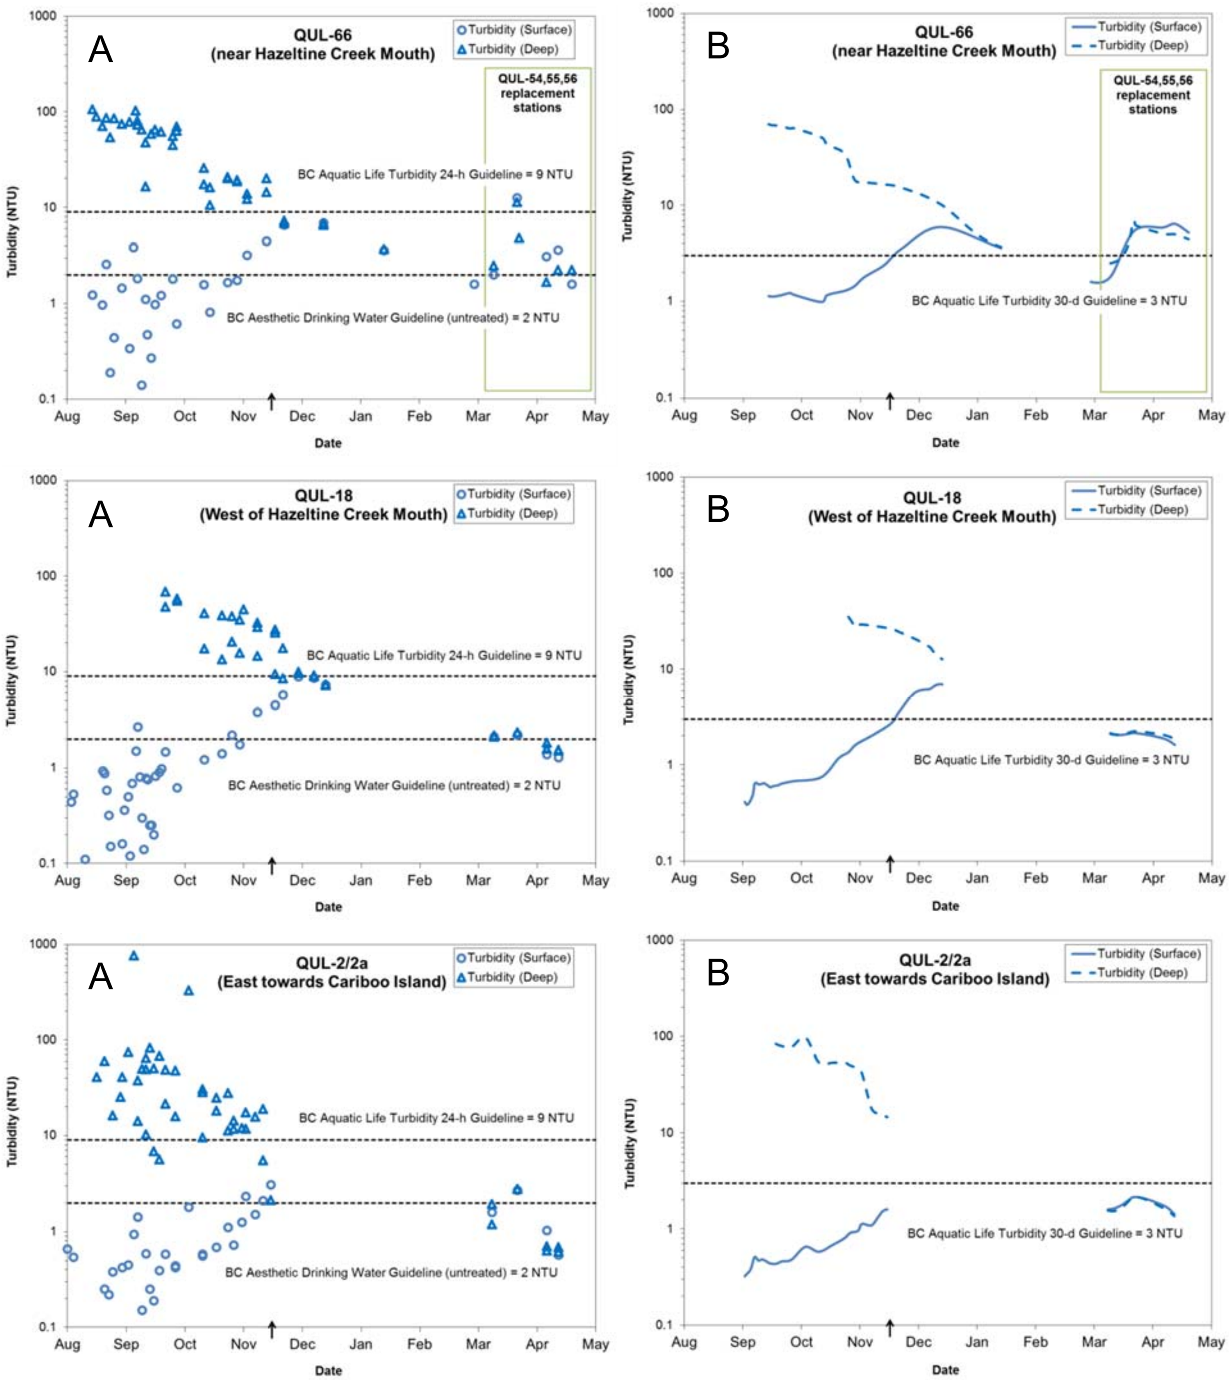


Note: The white arrow represents the approximate timing of mid-November turnover in Quesnel Lake.

Figure 12: Post-event Contours of In-situ Measured Turbidity at Station QUL-66, Quesnel Lake. Turbidity (NTU) shown on right hand axis.



Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake. Gaps represent >30 d between sampling. Baseline assumed ≤1 NTU with respect to BC WQG values.

Figure 13: Post-event Instantaneous (A) and Rolling 30-day Average (B) Concentrations of Turbidity at stations QUL-66, QUL-18, and QUl-2/2a, Quesnel Lake.

In mid- to late October, surface water began to cool and mix due to the lake turnover event. By mid-November measurements of temperature, turbidity, and specific conductivity were uniform throughout most of the water column. Turbidity at depth decreased to less than 10 NTU, which corresponded with an increase in turbidity in surface waters (Figure 13). This relatively small change in turbidity at the surface compared to deeper waters resulted in a cloudy appearance within the West Basin of the lake throughout the late fall and winter. By early spring (March and April 2015), turbidity at surface and depth decreased and was below 24-h and 30-d BC aquatic life WQGs (Figure 13). The exception to this was a few samples collected near the mouth of Hazeltine Creek (QUL-66) with slightly elevated turbidity that reflects localized input of particulate matter from Hazeltine Creek before erosion control works progressed to their current state. At stations further afield in both directions (QUL-18 towards Quesnel River and QUL-2/2a [pooled stations] towards Cariboo Island), turbidity remained low. Most recent samples show that turbidity is close to the maximum BC aesthetic drinking water guideline for untreated water (+1 NTU above baseline, when background is ≤5 NTU).

Dissolved oxygen was above the minimum requirements for aquatic life during all sampling events from August 2014 through February 2015. Sampling was discontinued from December 16 through to February 2015 at most stations in Quesnel Lake due to the inability to safely access off-shore stations.

Separate observations and data of Quesnel Lake water quality were recently published (Petticrew at al. 2015). The description of data obtained by these authors closely aligns with the findings of MPMC's team as provided here and in TetraTech (2015) as well as findings of BC MoE (2015c).

Quesnel River

Temperature changes in Quesnel River post-event reflected typical seasonal patterns as well as patterns reflective of transient "seiche" events. Dissolved oxygen was above the minimum requirements for aquatic life during all sampling events from August 2014 through February 2015. Specific conductivity in Quesnel River increased from 92 µS/cm until mid-December and has since remained relatively stable at approximately 140 µS/cm.

As discussed in the context of suspended particulate matter in Section 4.2.2.2 and shown in Figure 17 episodic peaks in turbidity concentrations were recorded three times in late summer and early fall (late August, early September, early October) and corresponded to observations of cloudy river water over several days. These "cloudy-water" events were the result of internal seiches in Quesnel Lake during the late summer and early fall and the upwelling of deep turbid water (see Figure 12) at the outflow of the lake into Quesnel River (as described by Tetra Tech 2015). Beginning in early November, turbidity increased more substantially and continually in the river as fall turnover in the lake caused the deep turbid water to be mixed throughout the water column. Turbidity in the river peaked in early December and declined to less than 2 NTU by mid-February. Turbidity in Quesnel River at the Likely Bridge is now less than 1 NTU.

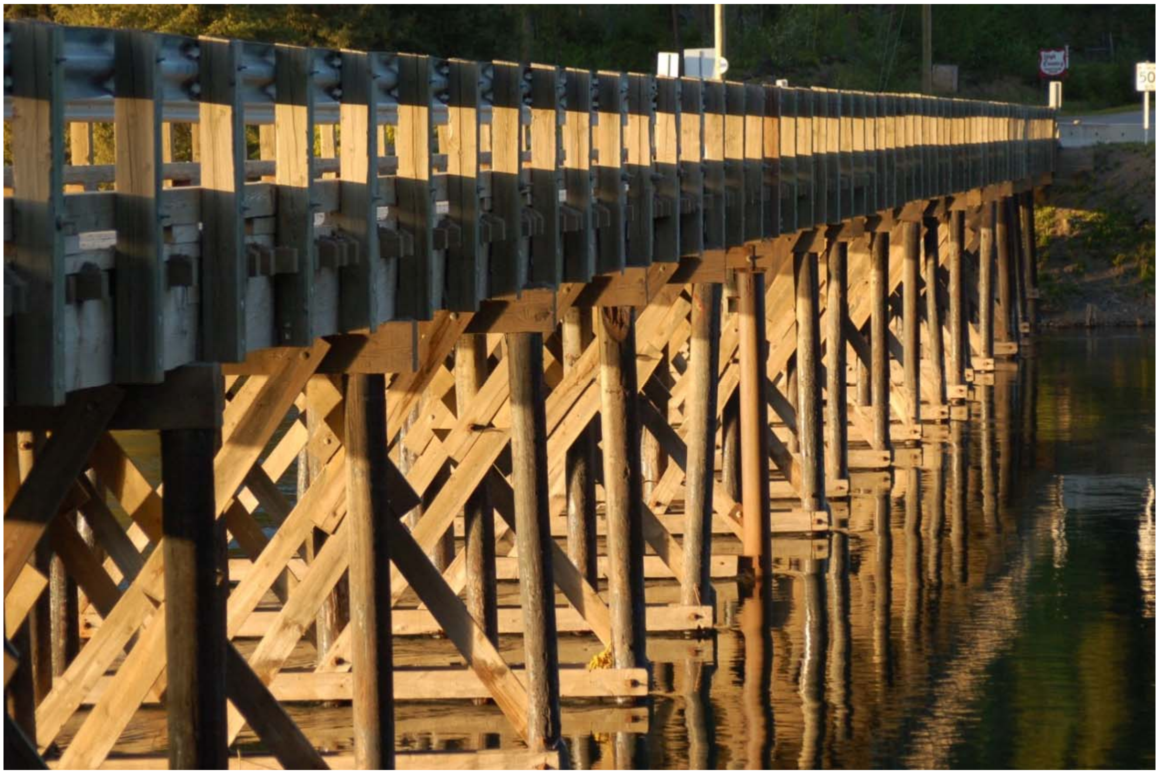


Figure 14. The turbidity of the Quesnel River at the Likely Bridge has decreased to less than 1 NTU. May 12, 2015 photo.

4.2.2.2 Suspended Particulate Matter

Background

Suspended particulate matter consists of suspended substrate particles (e.g., clay and silt), organic matter (e.g., detritus), planktonic organisms, and bacteria. It can be measured optically as turbidity or gravimetrically as TSS. Turbidity is a measure of water's cloudiness or haziness as determined by how much light can be transmitted or scattered through a sample; TSS is measured as the amount, by weight, of suspended particulate matter (solids) retained on a glass fiber filter. The relationship between turbidity and TSS depends on site-specific conditions, including particle size, colour, and reflective properties.

Turbidity and TSS data may be influenced by anthropogenic activities that affect waterbodies and watercourses, as well as natural, temporal (i.e., seasonal), and spatial phenomena (Caux et al. 1997). Under most natural conditions, soil erosion and weathering are the greatest contributors to turbidity, such as runoff during the spring freshet. Biological activity, such as the proliferation of planktonic organisms during warm summer months, may also have a seasonal effect on turbidity and TSS measurements (Chapman 1992).

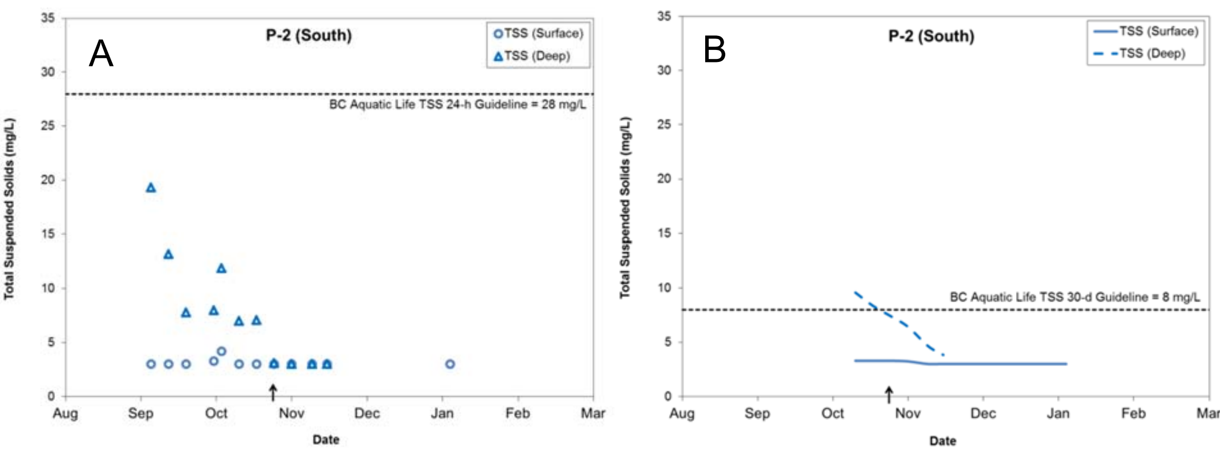
Elevated turbidity and TSS can have negative implications for drinking water quality and for aquatic life. Turbidity may affect drinking water quality by reducing the aesthetic appeal of water and/or reducing the effectiveness of water treatment methods. Turbidity and suspended solids affect light penetration, which, in turn, may affect photosynthetic organisms such as algae (Birtwell et al. 2008). As suspended sediments settle out of the water column, they can fill the interstitial spaces within aquatic substrate, thereby reducing the quantity and quality of cover and habitat available to macroinvertebrates, fish eggs, and fish fry. Elevated concentrations of suspended solids may affect fish health and survival by abrading or clogging the gills, altering behaviour (e.g., migration), and reducing the foraging efficiency of sight-feeding species (CCME 2002; Newcombe and Jensen 1996; Robertson et al. 2006). However, the potential for water quality impacts from suspended particulate matter and the extent of those impacts will depend on site-specific factors such as water velocity, particle size, and angularity, habitat characteristics, season, and other factors. Quantification of those effects is relevant to determining whether or not there is an impact.

Appendix F provides additional information on the measurement of turbidity and TSS, their occurrence and variability in the aquatic environment under natural conditions, and the BC MoE guidelines for protection of aquatic life and for drinking water quality

Polley Lake

TSS measurements over time recorded during the post event period at Station P2 are shown in Figure 15. Corresponding figures for Station P1 are provided in Appendix D: Section 1.0 and Appendix E: Section 1.1.

Concentrations of TSS at depth decreased to below detection by early November; concentrations in surface waters were rarely above detection (MDL = 3.0 mg/L). The same decreasing trend in concentrations at depth was observed for turbidity (Section 4.2.2.1); however, increased turbidity in surface waters following lake turnover was not reflected in changes to surface TSS. Instantaneous and 30-d average concentrations of TSS were lower than the 24-hour (h) and 30-d average BC WQGs. However, turbidity at depth was above the 24-h and 30-d average BC WQGs until lake turnover (Figure 9 and Figure 10).



Note: Arrow represents the approximate timing of late-October turnover in Polley Lake. Baseline assumed equal to MDL of 3.0 mg/L.

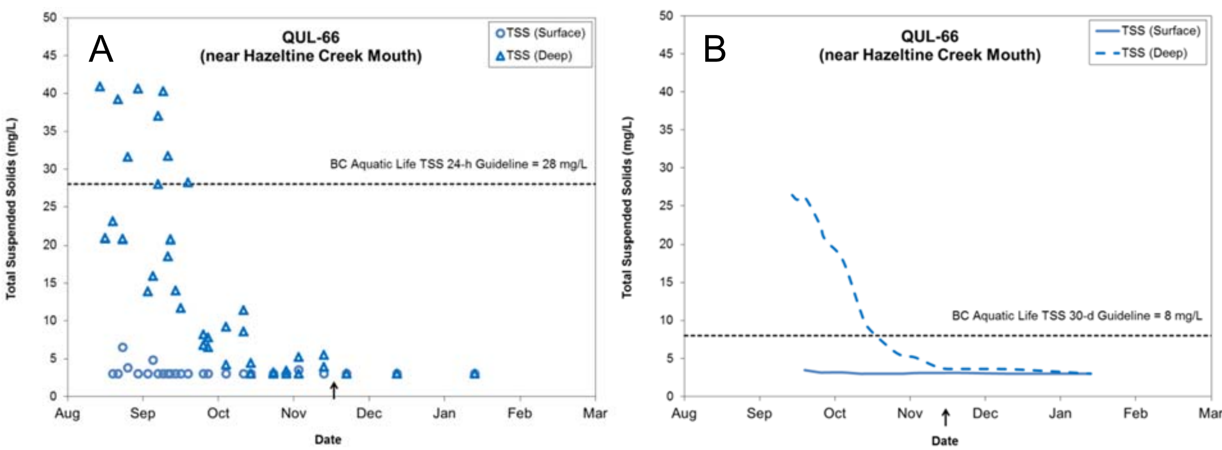
Figure 15: Post-event Instantaneous (A) and Rolling 30-day Average (B) Concentrations of Total Suspended Solids at Station P2, Polley Lake.

Quesnel Lake

Trends in TSS and turbidity were assessed at the five stations selected as representative stations in Section 3.4.2.1; i.e., QUL-66 (near the mouth of Hazeltine Creek), QUL-66a (north of QUL-66), and three stations further afield in the lake (stations QUL-21 northwest towards Quesnel River; QUL-2 east towards Cariboo Island; and QUL-120a located further east towards the main body of the lake). TSS measurements over time for Station QUL-66 are shown in Figure 16. Corresponding figures for the other stations are provided in Appendix E: Section 3.1.

At these stations, concentrations of TSS at depth decreased to near detection limits (3.0 mg/L) by mid-October, while turbidity remained elevated at depth (Section 4.2.2.1). The observed difference between the two measurements of particulate matter is likely the result of settling of larger particles (>1.5 µm measured as TSS) while smaller particles remained in suspension and were detected in turbidity measurements.

In surface waters, TSS was rarely detected before turnover and did not reflect increased turbidity in surface waters with lake turnover. Concentrations of TSS in most individual samples collected at surface and at depth were less than the 24-h BC WQGs.



Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake. Baseline assumed equal to MDL of 3.0 mg/L.

Figure 16: Post-event Instantaneous (A) and Rolling 30-day Average (B) Concentrations of Total Suspended Solids at Station QUL-66, Quesnel Lake.

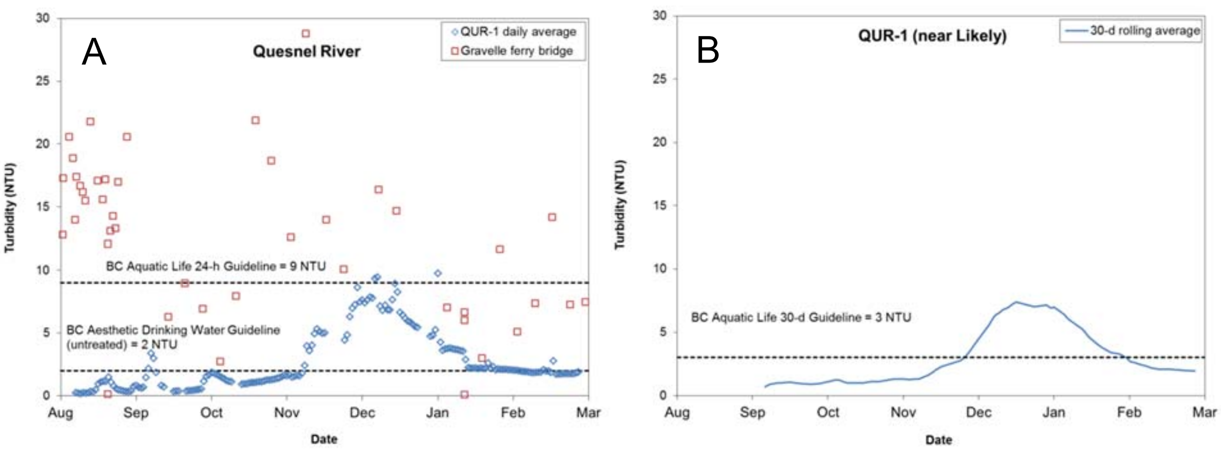
Trends in 30-d average TSS concentrations were more pronounced at Station QUL-66 close to the mouth of Hazeltine Creek, compared to other stations in the West Basin that are further away from the creek mouth to the west and the east. Close to the mouth of Hazeltine Creek 30-d average TSS concentrations were above the 30-d BC WQG until mid-October (Figure 16). At Station QUL-21 located towards the outflow to Quesnel River, 30-d average concentrations declined below the guideline by late September (Appendix E; Section 3.1). The 30-d BC WQG was not exceeded at the other three Quesnel Lake stations.

Available post-event data indicate that TSS concentrations and turbidity levels in Quesnel Lake did increase as a result of the event, particularly at depth, and post-event concentrations and levels were above BC WQGs. By September, TSS concentrations had decreased below the BC WQG, but turbidity remained elevated until early 2015.

Quesnel River

At Station QUR-1 located downstream of the lake outflow at Likely, at the Quesnel River Research Centre, concentrations of TSS were below BC WQGs and rarely detected post-event. TSS concentrations did not reflect the increases in turbidity that occurred following fall turnover in Quesnel Lake, but there was an increase in turbidity in the river from November to January with peak concentrations recorded in December (Figure 17). Turbidity concentrations were typically less than the 24-h BC WQG, but 30-d average turbidity levels were above the 30-d BC WQG from mid-November to early February. The observed difference between the two measurements of particulate matter likely reflects both the detection limit of TSS (3.0 mg/L) as well as the small particle size of suspended particles that would have passed through the glass fibre filter (1.5 µm).

At the Gravelle Ferry Bridge, which is more than 50 km downstream of Likely, BC MoE (2015d) reported that turbidity and TSS are commonly higher as compared to those measured near Likely. TSS concentrations ranged from 6.7 to 40 mg/L in samples collected between December 2014 and March 2015 at this downstream station. Turbidity at Gravelle Ferry Bridge was variable over time. Immediately after the event turbidity was as high as 15 to 20 NTU compared to less than 2 NTU at QUR-1 and at the time that turbidity peaked at Station QUR-1 in December, turbidity at Gravelle Ferry Bridge was almost twice as high (Figure 17) as it was at QUR-1. This suggests that sources of turbidity not related to the event influences water quality in the Quesnel River downstream of the town of Likely.



Quesnel River at Likely baseline turbidity assumed ≤1 NTU with respect to BC WQG values.

Figure 17: Post-event Instantaneous (A) and Rolling 30-day Average (B) Concentrations of Turbidity at Station QUR-1, Quesnel River. Turbidity measured at Gravelle Ferry Bridge also shown (BC MoE post-event data).

4.2.2.3 Metals

Background

Metals occur naturally in the environment as geochemical components of sediments, soils, and rocks. They can exist in dissolved form, adhered to particulates, as part of organic and/or inorganic complexes, and in various oxidation states (Campbell et al. 2006). Measures of total metal concentrations encompass all of these forms and do not necessarily reflect the bioavailable concentration of a metal that might be directly taken up by aquatic organisms potentially resulting in adverse effects (Chapman and Wang 2000; Chapman 2008; Singleton 1987). Metal accumulation and toxicity is dependent on metal bioavailability, which is influenced by exposure and toxicity modifying factors that include environmental exposure conditions as well as physiological and biological characteristics of aquatic organisms. Environmental exposure conditions that can influence metal toxicity and accumulation include pH, water hardness, and dissolved organic carbon (Campbell et al. 2006). For example, elevated concentrations of organic carbon can protect against metals toxicity (Wood et al. 2011; Meyer et al. 2012).

Metals adsorbed to or sequestered by particles are less bioavailable for direct uptake from the water by aquatic organisms than dissolved metals in the water column (Chapman et al. 1998; Luoma and Rainbow 2008). Total metals concentrations reflect both the proportion of metals associated with particles and that dissolved in the water column. Dissolved concentrations tend to provide a more realistic indication of the bioavailable concentration for direct uptake from the water, particularly in turbid receiving environments (Chapman and Wang 2000). However, the measure of “dissolved” metals is an operational definition based on whether the metal passes through a small (0.45 µm) filter (BC MWLAP 2013). Where particles are smaller than this size – which some of the particulates in Quesnel Lake were, metals that are associated with particulates will be measured as “dissolved” metals. Water quality guidelines for the protection of aquatic life are generally applied to total concentrations, but are derived from laboratory-based toxicity tests. In these tests, exposure concentrations are based on metals in solution from metal salts and the laboratory test water has a low level of suspended matter (typically clear water). Typically, these tests, while reporting in total metals, are based on dissolved and thus bioavailable metals. The application of WQGs to total concentrations measured in the environment can therefore be conservative, especially when those metals are part of the mineral matrix that makes up the particle.

Some metals are essential for the normal growth, development, and reproduction of organisms. Copper, chromium, and iron are essential metals, whereas aluminium is not. For example, copper is a co-factor in the function of important proteins and enzymes such as cytochrome, ascorbate oxidase, and plastocyanin (Chapman and Wang 2000). Organisms will tend to regulate their internal concentrations of essential metals within an optimal range; outside this small range deficiency occurs (insufficient metal) and toxicity (excess metal) (Chapman and Wang 2000, Campbell et al. 2006).

Aquatic organisms can take up metals from diet or water (e.g., across gills in fish). Bioconcentration (accumulation from water) and bioaccumulation (accumulation from water and diet) are relative to the concentrations in the environment: bioconcentration factors (BCFs) and bioaccumulation factors (BAFs) can be higher at low media concentrations than at higher media concentrations (i.e., BCFs and BAFs are inversely related to exposure concentrations) (Grosell 2012, Wood 2012). This pattern is likely because metals are taken up by facilitated transport (ion exchangers or channels), which can be saturated and are also physiologically regulated (Grosell 2012, Wood 2012). For example, when aqueous concentrations of copper are elevated, aquatic organisms such as plankton and fish will typically have higher body burdens of copper. However, the ratio of the concentration of copper in the tissue to the concentration in water can be lower than in environments with lower water concentrations, because in the low-concentration environment, the aquatic organism will selectively uptake the copper to meet its physiological needs.

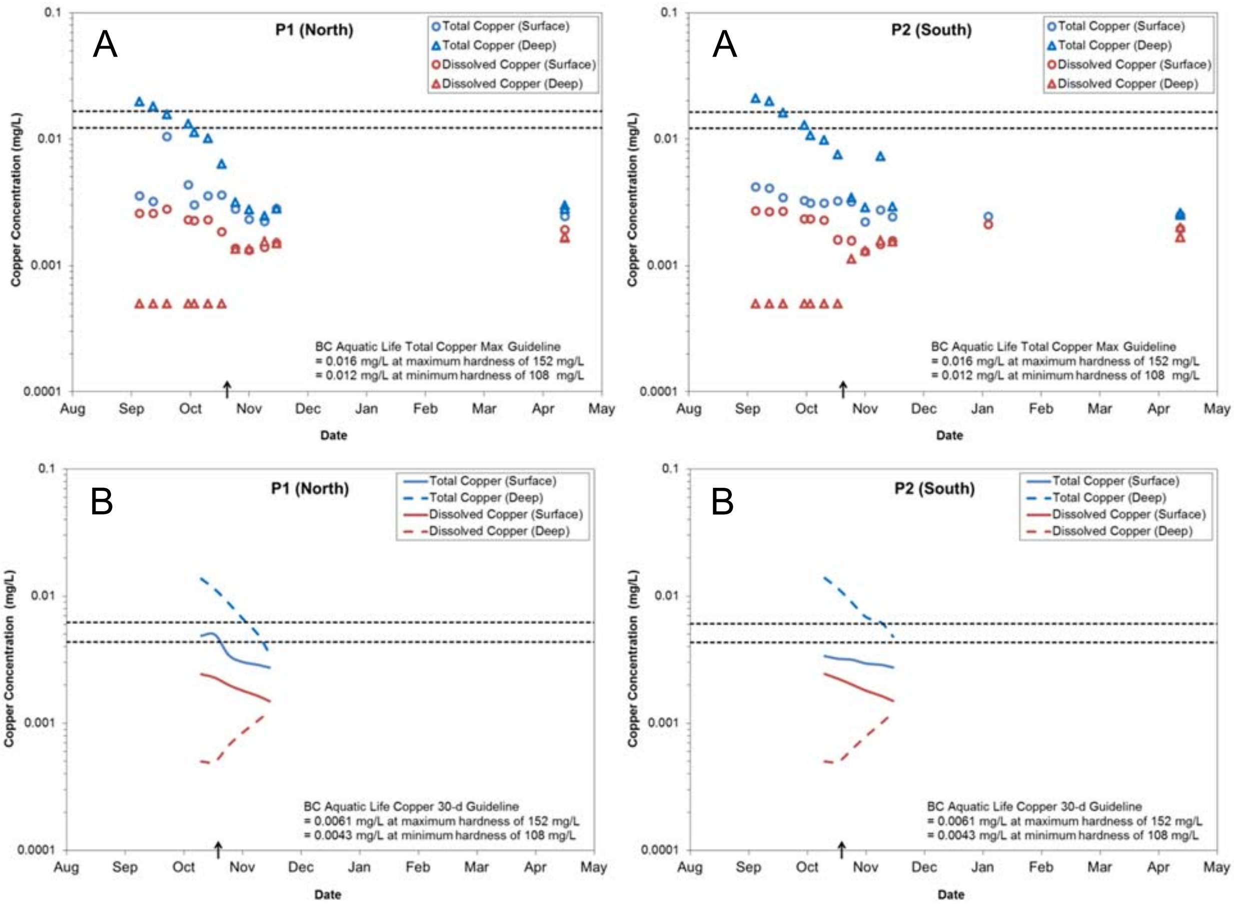
Bioaccumulation of essential metals will occur, but bioaccumulation does not necessarily indicate adverse effects, as metals in biota can be sequestered or excreted by various mechanisms (Fairbrother et al. 2007; Chapman 2008). Metallothioneins (in animals and bacteria) and phytochelatins (in algae, plants, and some fungi) are involved in both the regulation of essential metals and the detoxification of non-essential metals (Chapman and Wang 2000). These proteins and peptides are induced by the exposure to elevated metals, and will protect the aquatic organisms from metal toxicity by binding excess metals. Other detoxification strategies include sequestering metals in granules within the tissue, creating insoluble metal precipitates, or excreting (e.g., accumulating metals in the exoskeleton that can be shed during moulting) (Chapman and Wang 2000). Thus, metals in tissues of biota are divided into metabolically available metal and stored detoxified metal; toxicity does not depend on total accumulated metal concentration, but rather on a threshold concentration of internal metabolically available metal (Rainbow 2007; Luoma and Rainbow 2008).

Inorganic metals such as copper, aluminum, iron, and chromium do not biomagnify; only mercury and selenium can biomagnify, and only in their organic forms (Chapman and Wang 2000; Campbell et al. 2006; USEPA 2007; Chapman 2008). Biomagnification is defined as increasing concentrations of a substance solely via uptake from food up three or more trophic levels. Organic forms of mercury (methylmercury) and selenium (organoselenium) can biomagnify because biological uptake of these methylated forms of metals is efficient, yet elimination (excretion) is slow (e.g., Wiener et al. 2000, Stewart et al. 2010). Thus tissue concentrations of methylmercury and organoselenium are higher in successively higher trophic level organisms (e.g., predatory fish, fish-eating birds, humans) then would be expected based on concentrations in water or diet alone. Selenium is an essential element and is present in mineral supplements; however, mercury is not an essential element.

Copper

Polley Lake

Although initially elevated after the event, total copper concentrations decreased over time at the lake surface and at depth to concentrations below the maximum and the 30-d BC WQGs, and similar to median pre-event concentration (i.e., 0.002 mg/L, Appendix A, Table A-1). Instantaneous and 30-d average dissolved concentrations reported during the post-event period were lower than the maximum and 30-d average BC WQGs (Figure 18). Copper increases were not observed over the eight months following the event.



Note: Arrow represents the approximate timing of late-October turnover in Polley Lake.

Figure 18: Post-event Instantaneous (A) and Rolling 30-day Average (B) Total and Dissolved Copper Concentrations at Stations P1 and P2, Polley Lake.

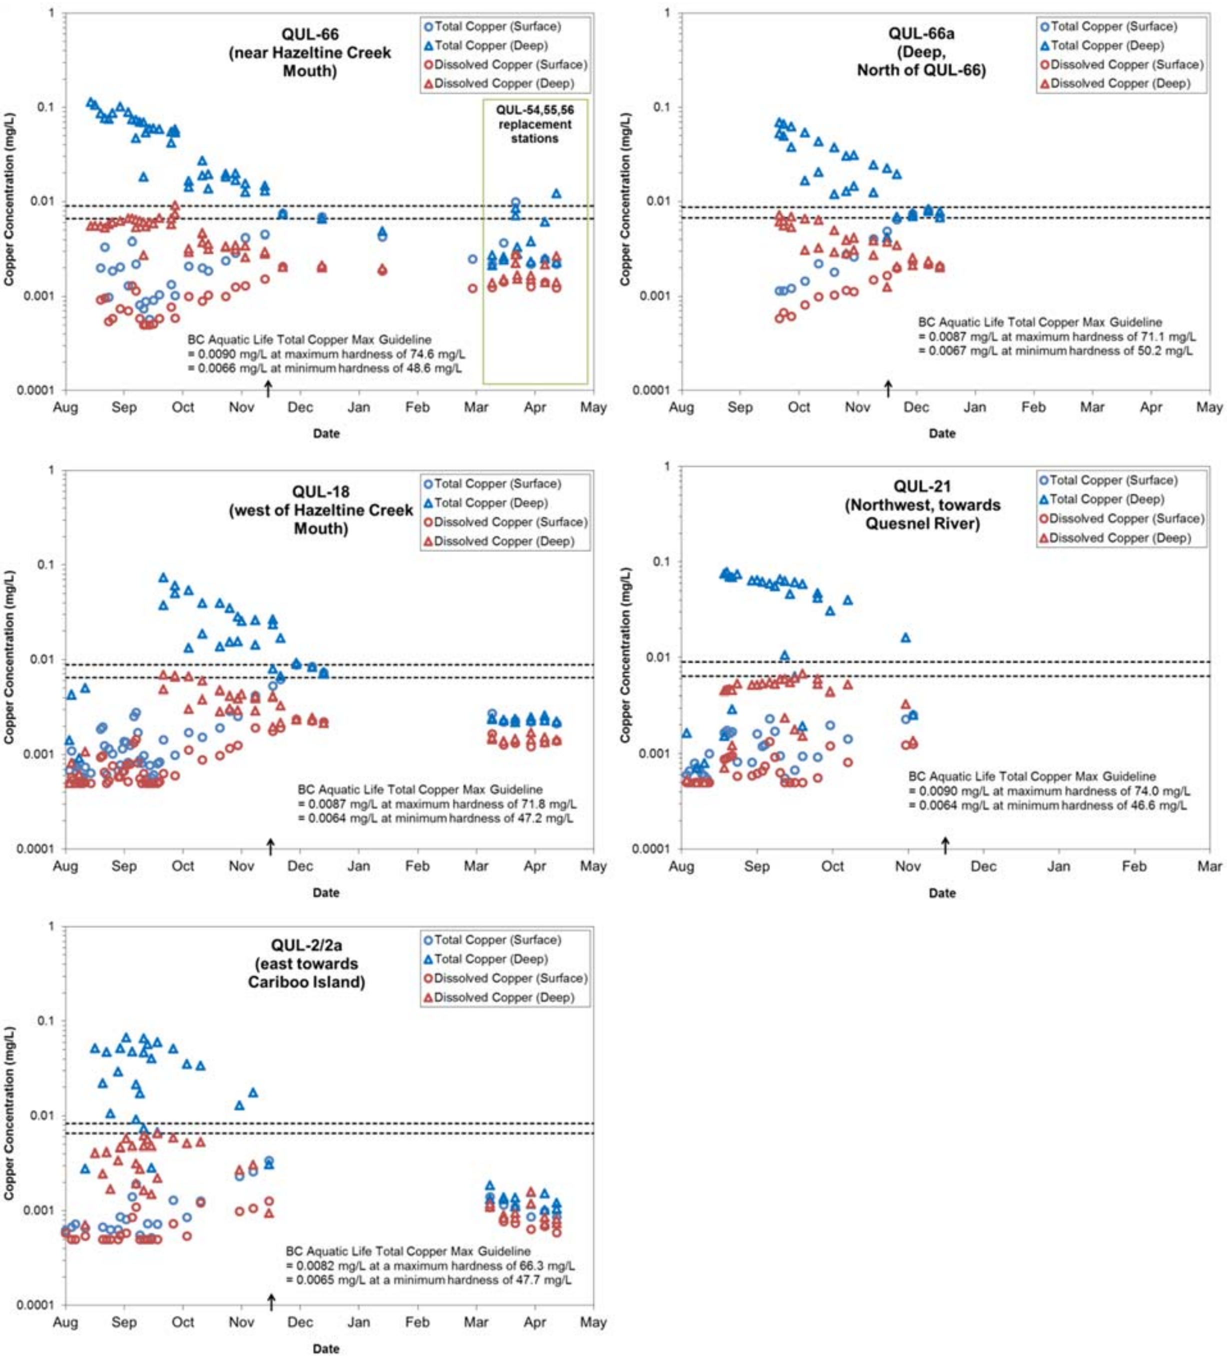
Quesnel Lake

Total and dissolved copper concentrations were assessed at the five stations selected as representative stations in Section 3.4.2.1; i.e., QUL-66 (near the mouth of Hazeltine Creek[10]), QUK-66a (a deeper station north of Station QUL-66), QUL-18 (west of Hazeltine Creek mouth), and two stations further afield in the lake in both directions (Station QUL-21 northwest towards Quesnel River and Station QUL-2/2a [pooled stations] east towards Cariboo Island).

At these stations, total concentrations at depth were higher than the maximum BC WQG, but the majority of total concentrations at surface were less than the guideline (Figure 19). Dissolved concentrations measured in most individual samples collected at surface and at depth were less than the maximum BC WQG, calculated using the lowest measured hardness. In the most recent samples collected in March and April, 2015, total and dissolved concentrations were less than maximum BC WQG at stations QUL-18 and QUL-2/2a. These results indicate that

[10] Monitoring at QUL-66 ceased at the end of February; to show changes in copper concentrations at this general location since March, data from replacement near-field stations QUL-54, QUL-55, QUL-56 were used.

concentrations were initially elevated due to the event, but declined over the sampling period to concentrations below the BC WQG in 2015. An exception to this general observation was four total copper measurements near the mouth of Hazetline Creek that approximated or were above the guideline in March and April. The corresponding dissolved copper concentrations for these measurements were below the BC WQG as were the other total measurements. Turbid waters in Hazeltine Creek flow may have resulted in more variable total measurements in March and April; however, erosion control works completed since have reduced turbid water in Hazeltine Creek.

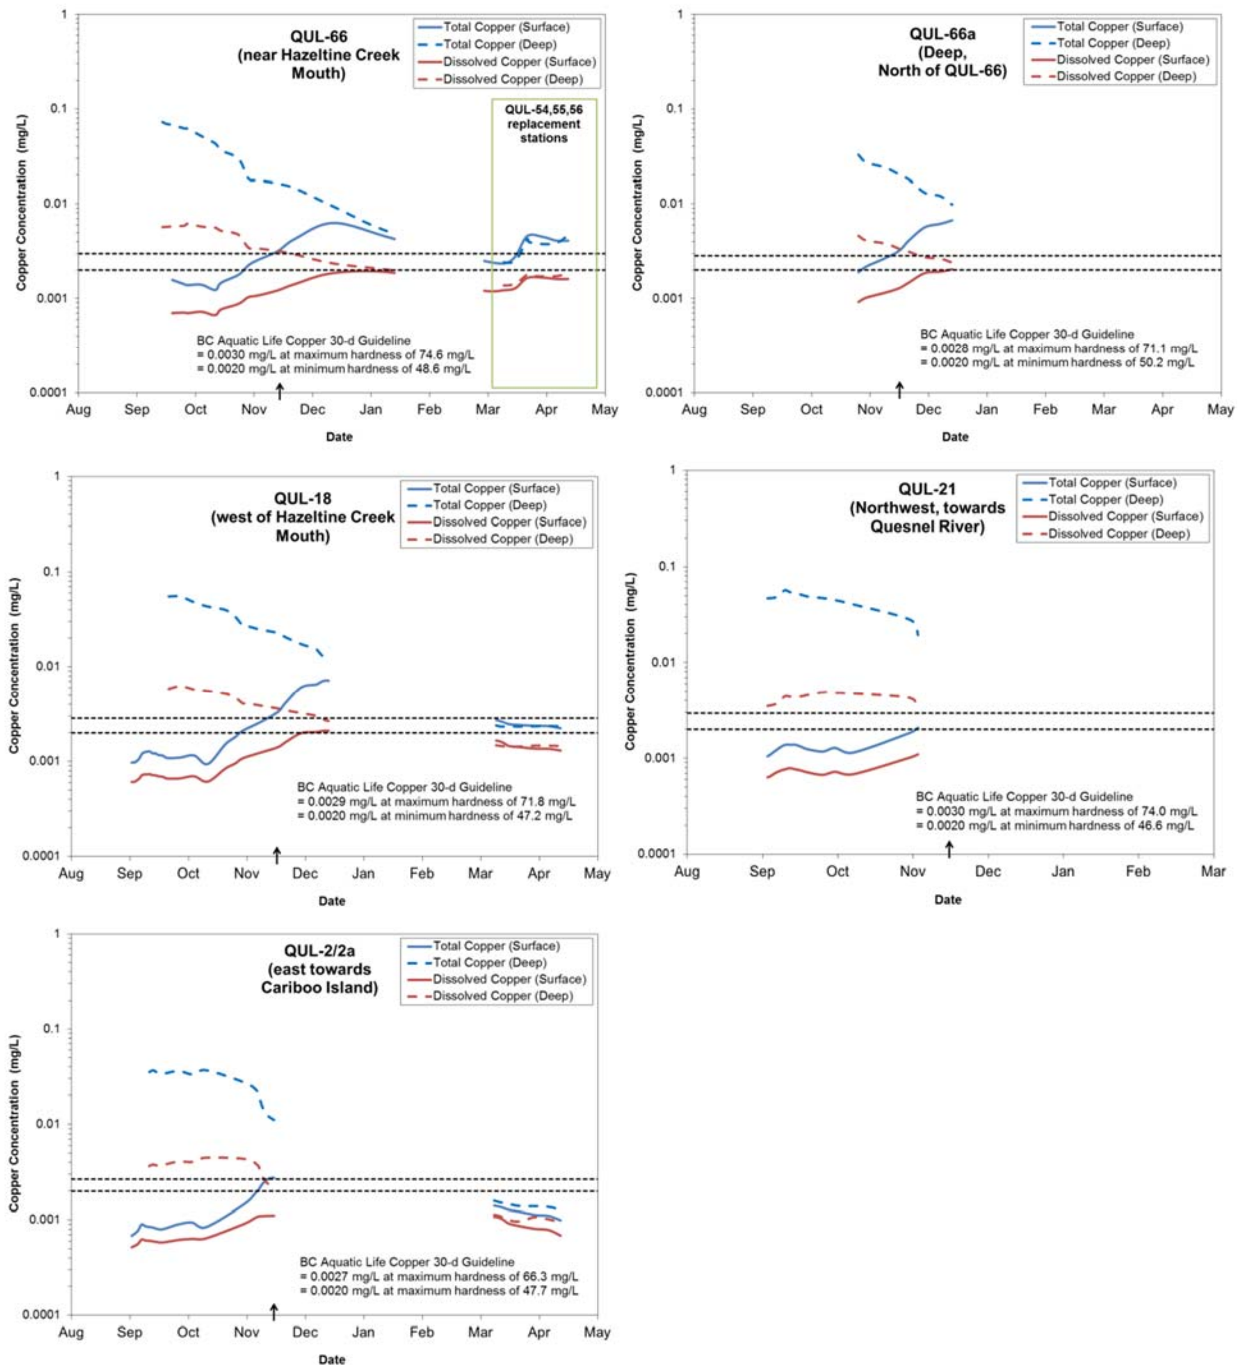


Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake.

Figure 19: Post-event Instantaneous Total and Dissolved Copper Concentrations at Stations QUL-66, QUL-66a, QUL-18, QUL-21, and QUL-2/2a, Quesnel Lake.

The rolling 30-d average concentrations showed similar trends prior to lake turnover at each of the representative stations: 30-d average total and dissolved concentrations were higher at depth than at surface, and concentrations at depth were above the 30-d average BC WQG (Figure 20).

Trends in 30-d average concentrations were more pronounced at stations closer to the mouth of Hazeltine Creek (stations QUL-66, QUL-66a, and QUL-18) relative to stations further afield in Quesnel Lake (Station QUL-21 northwest towards Quesnel River and Station QUL-2/2a to the east towards Cariboo Island). At stations QUL-66 and QUL-18, 30-d average total and dissolved concentrations at depth declined, particularly after the lake turnover in November, such that 30-d average dissolved concentrations at these stations were below the 30-d average BC WQG based on minimum hardness by March (Figure 20). Total concentrations remained above the guideline. Simultaneously, the 30-d average total and dissolved concentrations at surface increased and were the same as the concentrations at depth within a couple of months after lake turnover. The trends suggest that the lake waters were mixed after lake turnover, such that there was less of a difference between total and dissolved concentrations at surface and at depth and that concentrations were declining over time. Further afield in Quesnel Lake at Station QUL-2/2a, total and dissolved concentrations were below 30-d average BC WQG by March.



Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake. Gaps represent >30 d between sampling.

Figure 20: Post-event Rolling 30-day Average Total and Dissolved Copper Concentrations at Stations QUL-66, QUL-18, QUL-21, and QUL-2/2a, Quesnel Lake.

Quesnel River

Instantaneous and 30-d average total copper concentrations in grab samples collected in Quesnel River near the town of Likely (QUR-1) were higher than maximum and 30-d average BC WQGs; the highest total copper concentrations were measured at the beginning of December (Figure 21). Rolling 30-d average total copper concentrations declined from a peak in January to the 30-d average BC WQG in mid-April.

In comparison, dissolved copper concentrations in grab samples were substantially lower than the maximum BC WQG throughout the sampling period (Figure 21). Rolling 30-d average dissolved concentrations were higher than the 30-d average BC WQG for a short time between December and mid-January (Figure 21). However, this 30-d average BC WQG was conservatively calculated using the minimum measured hardness for all individual samples analyzed during the post-event period. When calculated using the 30-d average hardness associated with these samples, the 30-d average dissolved concentrations were less than the applicable BC WQGs.

BC MoE reports on water samples collected from two locations on the Quesnel River: at the Likely Bridge, which is upstream of Station QUR-1, and the Gravelle Ferry Bridge, which is more than 50 km downstream of Likely. Post-event water quality results at Likely Bridge have been consistent with MPMC samples collected at Station QUR-1. BC MoE (2015d) reported that pre-event water samples collected at the Gravelle Ferry Bridge exceeded BC WQGs for total copper as well as total chromium and dissolved aluminum. BC MoE (2015d) noted that the Quesnel River at the Gravelle Ferry Bridge receives inputs from several smaller tributaries and one large river (Cariboo River) and that the observed water quality is influenced by factors other than just Quesnel Lake. Prior to and immediately after the event, total copper concentrations at Gravelle Ferry Bridge were more than four times higher than measured at Likely (Figure 21), indicating that there are sources of particulate bound metals entering the river system between these locations. Therefore, there is the potential for sources of turbidity not related to the event to influence water quality downstream of Likely (as discussed in Section 4.2.2.2).

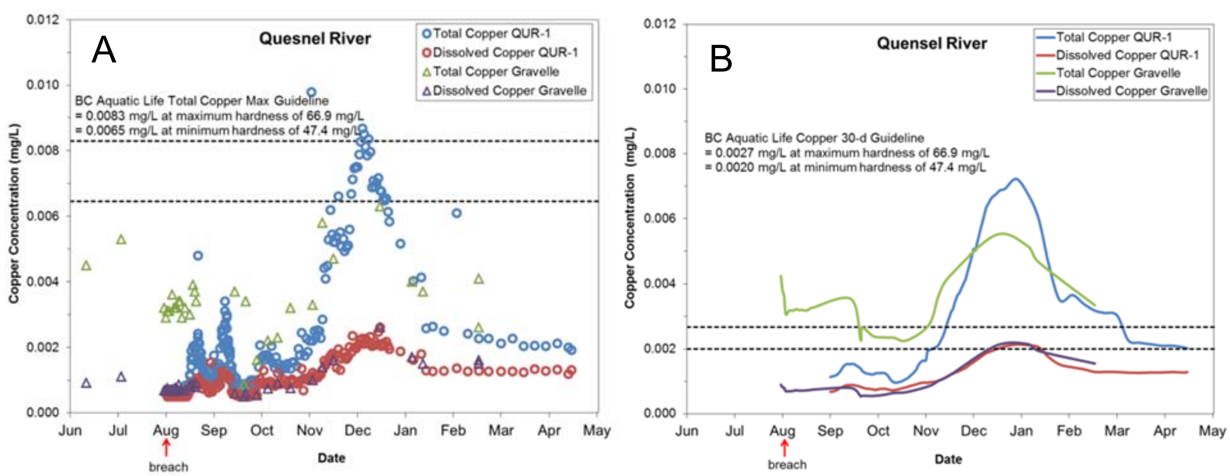


Figure 21: Post-event Instantaneous (A) and Rolling 30-day Average (B) Total and Dissolved Copper Concentrations at Station QUR-1 near Likely and at the Gravelle Ferry Bridge, Quesnel River.

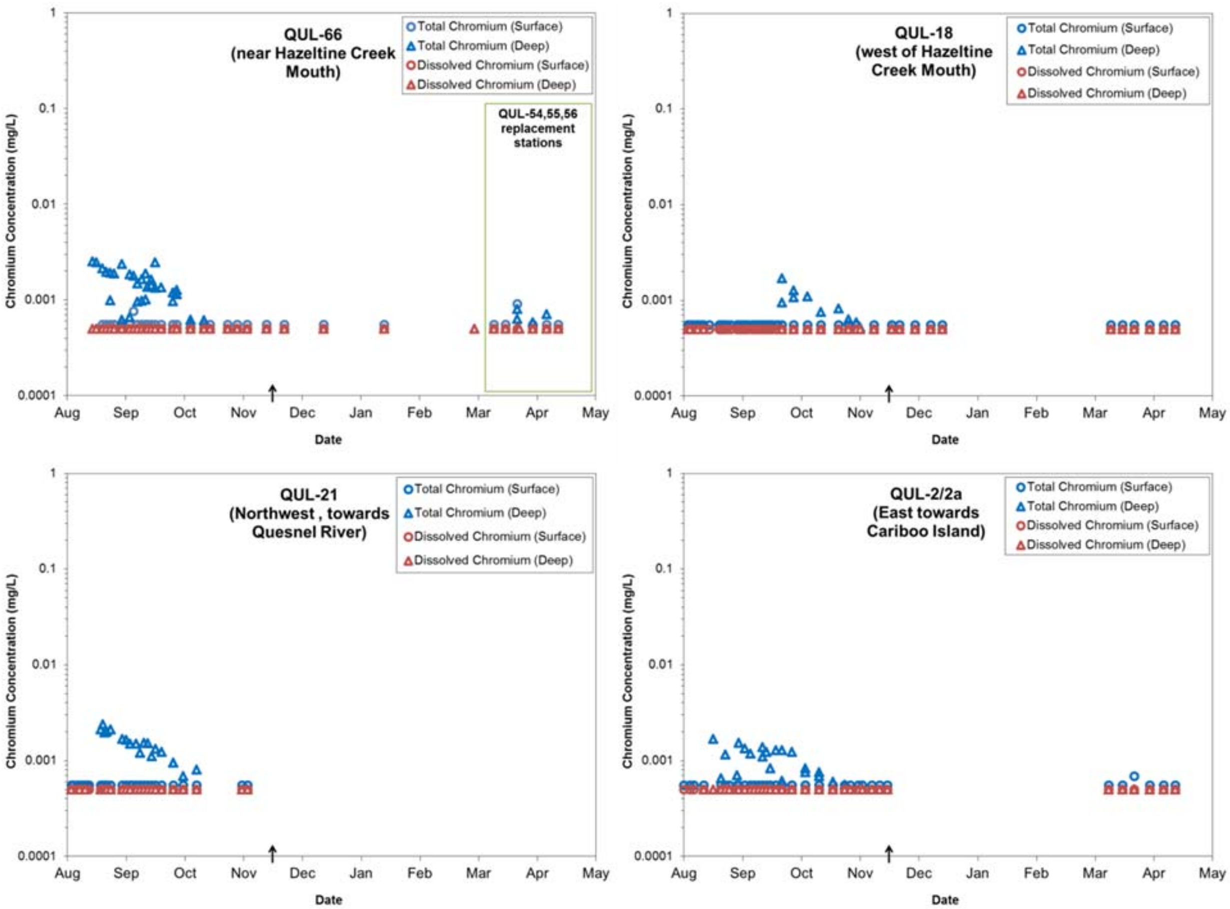
Chromium

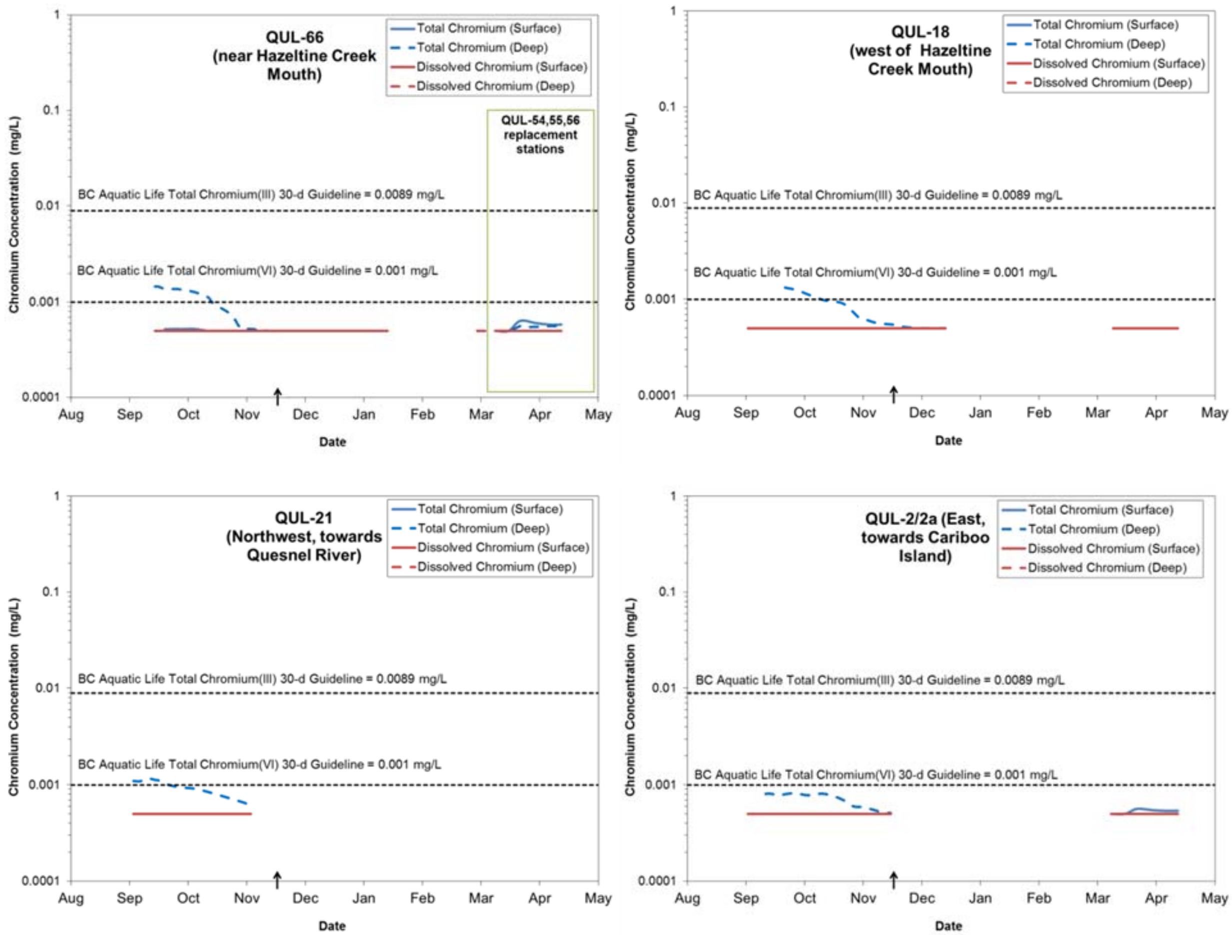
Quesnel Lake

Total chromium concentrations at depth were higher than the 30-d BC WQG after the event at near-field stations close to the mouth of Hazeltine Creek, but declined to below the most conservative guideline in October (Figure 22 and Figure 23). Total concentrations at surface were always less than the guideline and several results were reported as less than the detection limit. Dissolved chromium was not detected in samples collected at surface and at depth. These results indicate that concentrations were initially elevated due to the event, but declined over the sampling period.



Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake.

Figure 22: Post-event Instantaneous Total and Dissolved Chromium Concentrations at Stations QUL-66, QUL-18, QUL-21, and QUL-2/2a, Quesnel Lake.



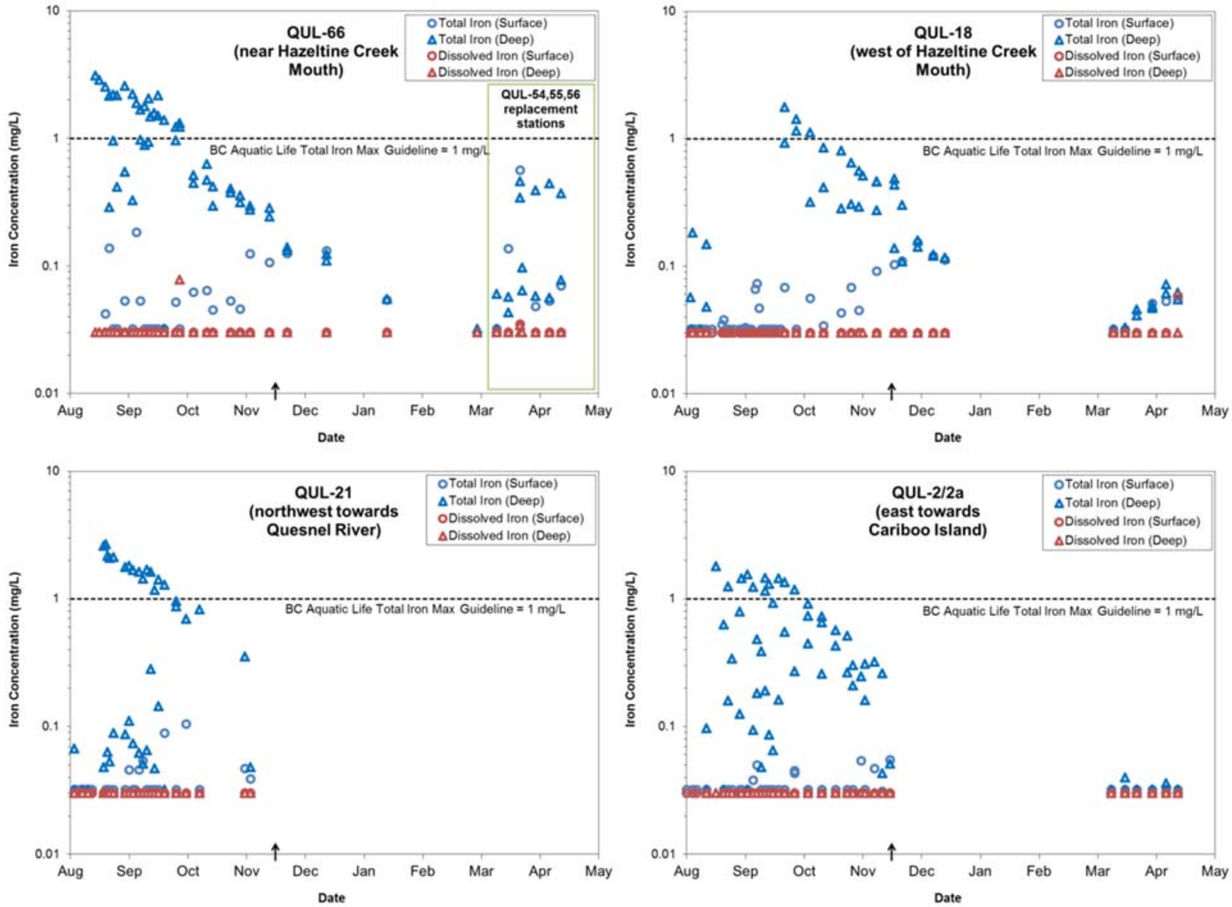
Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake. Gaps represent >30 d between sampling.

Figure 23: Post-event Rolling 30-day Average Total and Dissolved Chromium Concentrations at Stations QUL-66, QUL-18, QUL-21, and QUL-2/2a, Quesnel Lake.

Iron

Quesnel Lake

Total iron concentrations at depth were higher than the maximum BC WQG immediately after the event, and declined below the guideline by October (Figure 24). There was no obvious temporal or spatial trend in total concentrations at surface; values were always below the maximum BC WQG. Dissolved iron was typically not detected in individual samples collected at surface or at depth. These results indicate that total iron concentrations at depth were initially elevated due to the event, likely in association with suspended particulate matter, but declined over the sampling period.



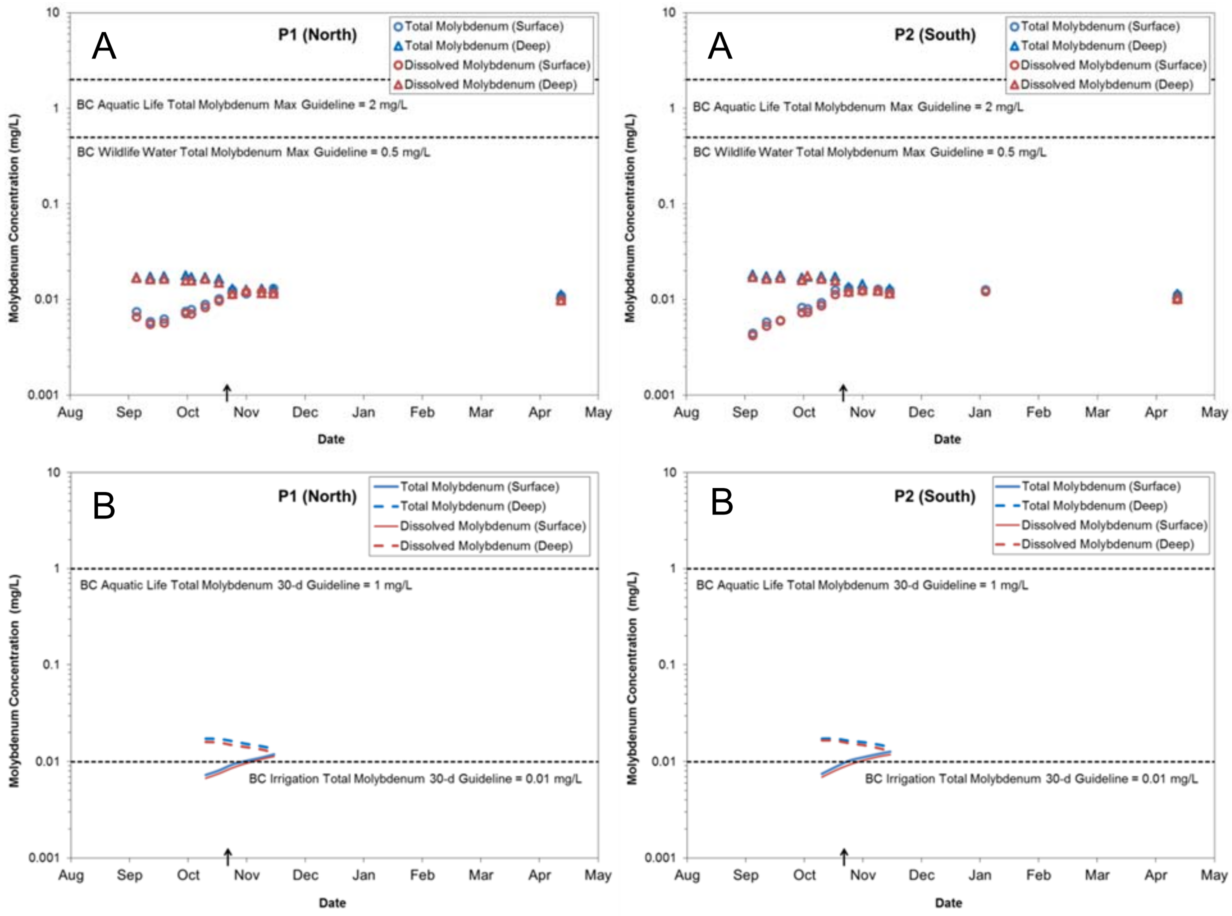
Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake.

Figure 24: Post-event Instantaneous Total and Dissolved Iron Concentrations at Stations QUL-66, QUL-18, QUL-21, and QUL-2/2a, Quesnel Lake.

Molybdenum

Polley Lake

Total and dissolved molybdenum concentrations were below the most conservative maximum BC WQG for wildlife (Figure 25). Thirty-day rolling average concentrations calculated were above the most sensitive long-term average BC WQG at depth before and after turnover and after turnover close to the lake surface (Figure 25). Discrete samples taken at surface and at depth in January and April were below or approximated this 30-d guideline conservatively applied to address exposure to potentially sensitive ruminant wildlife. Swain (1986) suggested that wildlife would be less susceptible to molybdenosis than domesticated ungulates because wildlife are not confined to one area and will forage from a variety of food sources. Harmful effects due to moose and deer that may have foraged on plants adjacent to or within Polley Lake are considered unlikely based on the low proportion of the diet of moose or deer these plants would be expected to represent. Furthermore, although toxicity data for wildlife ruminants are limited, available data for deer suggests they are more tolerant than sheep or cattle (Swain 1986).



Note: Arrow represents the approximate timing of late-October turnover in Polley Lake.

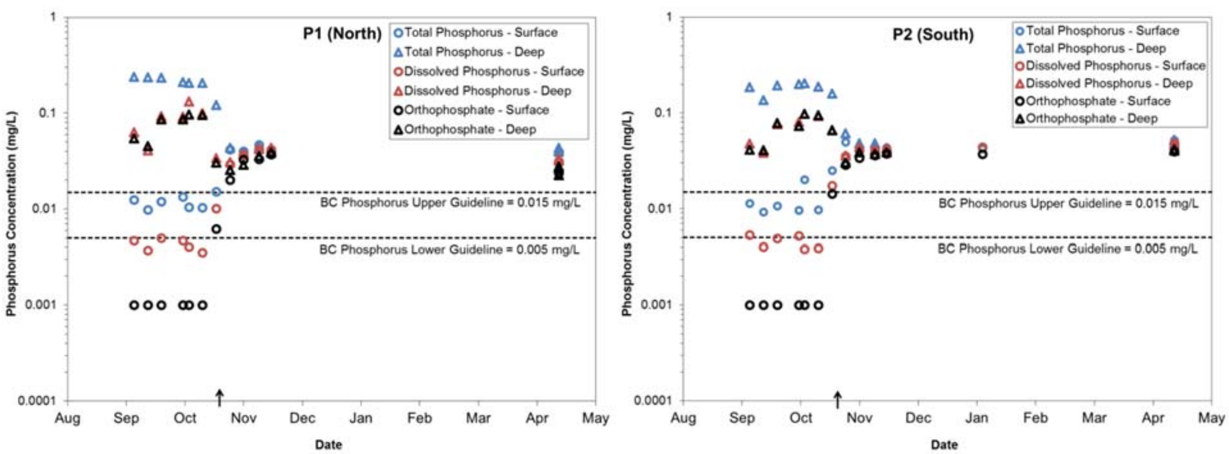
Figure 25: Post-event Instantaneous (A) and Rolling 30-day Average (B) Total and Dissolved Molybdenum Concentrations at Stations P1 and P2, Polley Lake.

4.2.2.4 Total Phosphorus

Unlike some of the nitrogen forms (ammonia, nitrite), phosphorus is not toxic to aquatic biota. However, given that primary productivity in freshwater lake environments tends to be limited by phosphorus, relative changes in lake phosphorus concentrations due to the event were evaluated (Environment Canada 2004). The BC WQG for TP in lakes is intended to be applied to the spring turnover concentration or the mean epilimnetic growing season concentration (e.g., May to September). Although post-event data were collected in the latter portion of the summer and into the fall, TP concentrations at surface and depth in Polley and Quesnel lakes were compared to the BC WQG range for lakes (i.e., 0.005 to 0.015 mg/L; BC MoE 2015a).

Polley Lake

Prior to the event, Minnow (2014) described a progressive increase in phosphorus concentrations in Polley Lake that resulted in a change in trophic status from oligotrophic/mesotrophic during the baseline (1989 to 1996) to mesotrophic/eutrophic in 2012 (Appendix A: Table A-1). After the event, concentrations of TP at the surface were within the 2009 to 2013 pre-event range reported by Minnow (2014). At depth, TP concentrations were substantially higher and were elevated above pre-event concentrations (Appendix A, Table A-1 and Minnow 2014) and above the upper limit of the BC WQG (Figure 26). Dissolved phosphorus and orthophosphate were also elevated at depth. Relatively lower concentrations of dissolved compared to total phosphorus suggested that a proportion of the TP was bound to or part of the mineral matrix of particulates present at depth. A common geologic source of phosphorus is the mineral apatite, which was part of the mineral matrix of the tailings particles. In deep samples, concentrations of dissolved phosphorus and orthophosphate were similar, indicating that most of the dissolved phosphorus would have been available for uptake by plants. In contrast, the surface samples contained orthophosphate concentrations near or below the detection limit. During fall turnover, concentrations of total and dissolved phosphorus, and orthophosphate from both surface and deep samples converged to median pre-event concentrations (i.e., 0.02 to 0.03 mg/L; Appendix A, Table A-1) and remained above the upper limit of the BC WQG in subsequent samples (Figure 26).



Note: Arrow represents the approximate timing of late-October turnover in Polley Lake.

Figure 26: Post-event Instantaneous Total and Dissolved Phosphorus and Orthophosphate at Stations P1 and P2, Polley Lake.

Quesnel Lake

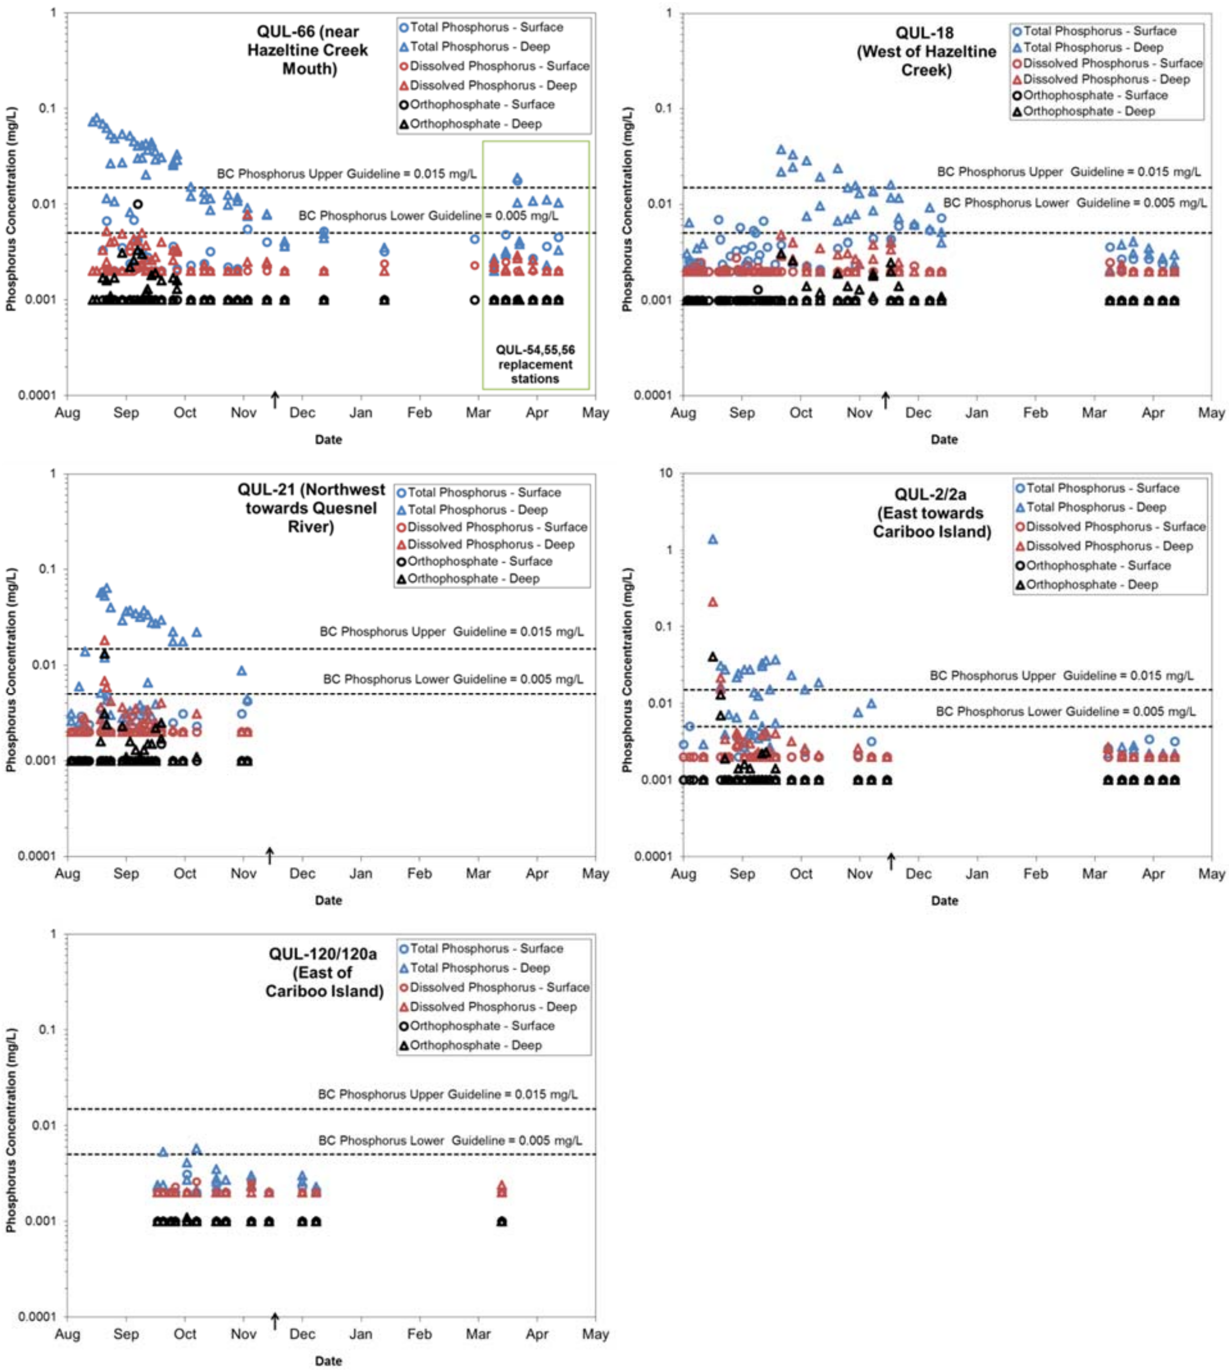
Similar to Polley Lake, total and dissolved phosphorus and orthophosphate were higher in deep water samples than surface waters.

Total and dissolved phosphorous concentrations were assessed at the five stations selected as representative stations in Section 3.4.2.1; i.e., QUL-66 (near the mouth of Hazeltine Creek[11]), QUL-66a (a deeper station north of Station QUL-66), QUL-18 (west of Hazeltine Creek mouth), and two stations further afield in the lake in both directions (Station QUL-21 northwest towards Quesnel River and Station QUL-2/2a east towards Cariboo Island).

[11] Monitoring at QUL-66 ceased at the end of February; to show changes in copper concentrations at this general location since March, data from near-by stations QUL-54, QUL-55, QUL-56 were used.

After the event, TP concentrations at depth were elevated above pre-event concentrations (Appendix A, Table A-1), concentrations measured outside of the West Basin (i.e., QUL-120/120a), and the upper limit of the BC WQG (Figure 27). At the surface, where suspended particulate concentrations were low, TP was not elevated above pre-event concentrations or guidelines. A comparison of total and dissolved phosphorus concentrations at depth suggests that a large proportion of the TP was bound to particulates, because mean dissolved concentrations were much lower. The association of TP with the presence of particulate material may be a reflection of the phosphate mineral apatite or inputs of soil and organic debris associated with the debris that flowed down Hazeltine Creek to Quesnel Lake as a result of the event.

Concentrations of TP at depth decreased over time, such that concentrations measured after fall turnover were below guidelines and similar to surface water concentrations (Figure 27). The observed increase in TP concentrations in the spring at depth at Station QUL-66 likely reflects input of particulate matter from Hazeltine Creek. Post-event, dissolved phosphorus and orthophosphate concentrations at surface and depth were typically below the median pre-event concentration (i.e., 0.003 mg/L; Appendix A, Table A-1), changed little over time, and in surface water samples were frequently near or below detection limits. The potential impact of changes in phosphorus concentrations on aquatic life in Quesnel Lake is discussed further in Golder (2015d).



Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake.

Figure 27: Post-event Instantaneous Total and Dissolved Phosphorus and Orthophosphate at Near Field Stations QUL-66, QUL-18, QUL-21, QUL-2/2a and Far Field Station QUL-120/120a, Quesnel Lake.

4.2.3 Evaluation of Copper Bioavailability

Of the metal COPCs evaluated in the receiving environment, copper was the COPC of primary interest because total and dissolved forms reported to be above BC WQGs during the post-event period (Section 4.2.2.3). The following evaluation of copper bioavailability in the receiving environment considers the relationship between turbidity and copper in addition to geochemical speciation modelling undertaken for Quesnel Lake and Quesnel River.

4.2.3.1 Relationship between Turbidity and Copper

Measures of total metal concentrations in water include metals adsorbed to particulate matter, thus there is often a correlation between total metal concentration and turbidity or total metal concentration and TSS. In contrast, concentrations of metals in truly dissolved forms have no correlation with particulate matter. Due to the amount of materials, including fine clays and organic materials, which were deposited into the downstream environment after the event, as well as the subsequent periods of turbid conditions, the correlation between turbidity and total and dissolved copper was examined for the receiving environment.

Correlation analysis was conducted on log-transformed values of in-situ measured turbidity and concentrations of both total and dissolved copper to determine Spearman's correlation coefficients and p-values. Correlation was considered significant at p-values less than or equal to (≤) 0.05; plots and statistics are shown for the representative stations in Polley Lake, Quesnel Lake, and Quesnel River in Appendix G.

For each of the representative stations, there was a significant positive correlation between total copper concentration and turbidity. In Polley Lake, there was a significant negative correlation between dissolved copper concentration and turbidity; dissolved copper concentrations were below method detection limits in samples with the highest turbidity (Figure 28 and Appendix G). At each of the Quesnel Lake stations and the one station in Quesnel River, there was a significant positive correlation between dissolved copper concentration and turbidity (Figure 28 and Appendix G). These relationships suggest that measures of dissolved concentrations may have included fine particulate matter that passed through the 0.45-μm filter, particularly in Quesnel Lake. Laser diffraction particle size analysis of water samples collected at surface and depth from stations QUL-66 and QUL-18 in November 2014 showed that particles less than 0.45 μm comprised up to 6% (v/v) of the particle size distribution (MPMC unpublished data). Therefore, the reported dissolved metals concentrations may have overestimated the metal concentration that would have been bioavailable for direct uptake from the water by aquatic biota. Copper adsorbed to or sequestered by particulates could have potentially been taken up by aquatic organisms via dietary exposure, but as discussed in Section 4.2.3.2 fish have been shown to regulate and internally compartmentalize dietary copper, thus maintaining homeostasis. The potential for copper accumulation in aquatic organisms in Quesnel Lake due to waterborne and dietary exposure routes is addressed in Golder (2015d).

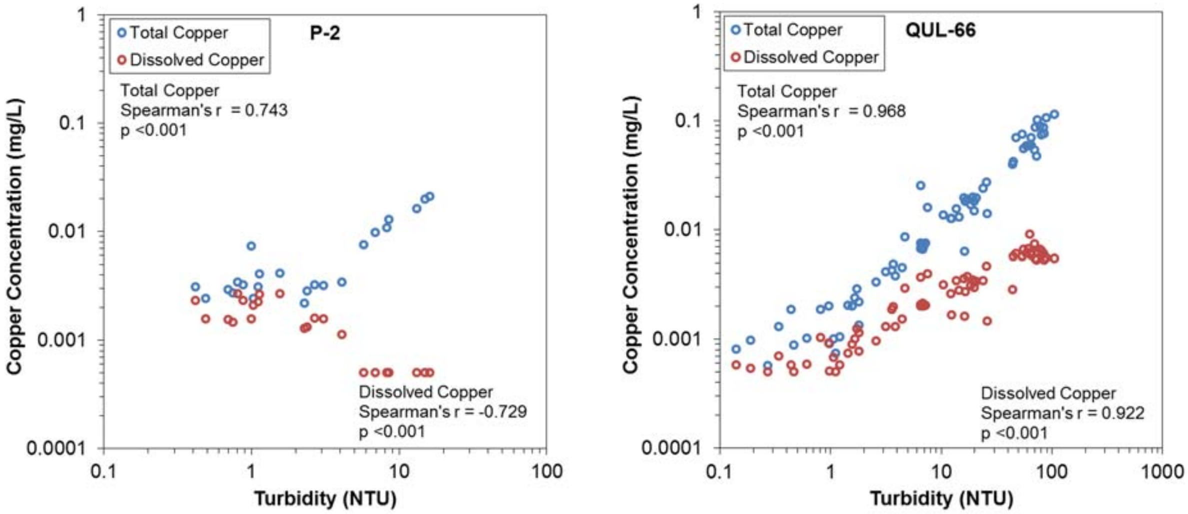


Figure 28: Correlation between turbidity and total and dissolved copper at Station P-2 in Polley Lake and Station QUL-66in Quesnel Lake post-event.

4.2.3.2 Copper Speciation Modelling

Copper occurs in surface waters in several forms or "species", depending on exposure conditions in the receiving environment, such as pH, alkalinity, hardness, salinity, and dissolved organic matter (Campbell et al. 2006). Dissolved copper species include free ionic copper (Cu^{2+}), copper hydroxides ($CuOH^{+}$ and $Cu(OH)_2$), copper carbonates ($CuCO_3$, $Cu(CO_3)_2^{2-}$), and copper bound to dissolved organic carbon (Cu-DOC). An understanding of the speciation of the "dissolved" metal fraction (per operational definition of <0.45 µm-filter) provides a truer measure of the bioavailability because scientific knowledge indicates it is the free metal species that is typically bioavailable for uptake from the water, with the potential to illicit adverse effects (Campbell 1995; Campbell et al. 2006). The particulate fraction also included in the measurement of total copper can potentially also be taken up by aquatic organisms through the dietary exposure route. Dietary copper uptake by fish has been shown to be regulated by the liver before being discharged via bile excretion and the kidneys, thus maintaining homeostasis (Miller et al. 1992, 1993). The potential for copper accumulation in aquatic organisms in Quesnel Lake due to waterborne and dietary exposure routes is addressed in Golder (2015d).

With respect to waterborne exposure addressed here in the WQIA, free ionic Cu^{2+} is the most bioavailable form and so has the greatest potential for toxicity to aquatic life, although copper-hydroxide complexes can also be bioavailable to a lesser extent and can thus also contribute to toxicity (Grosell 2012). Copper tends to be more bioavailable, and thus more toxic to aquatic life in surface waters having high dissolved copper concentrations, low ionic strength, low pH, and low DOC, as the copper will be predominantly present as the free ionic Cu^{2+} under such conditions (Grosell 2012). In freshwaters characterized by alkaline pH, copper-carbonate complexes tend to dominate.

Speciation modelling reported in Golder (2015c; Appendix H) estimated copper speciation at the representative stations assessed in Quesnel Lake and Quesnel River using the pH Redox Equilibrium in C language (PHREEQC) computer geochemical equilibrium modeling program (Parkhurst and Appelo 1999). The model output made it possible to estimate the proportion of copper bioavailable under site-specific water chemistry conditions at the representative Quesnel Lake stations. The PHREEQC program computes metal species and their concentrations based on inputs of water metal concentration and water chemistry parameters known to affect the speciation of the metal in question.

The speciation modelling suggested that the bioavailable fractions of the reported dissolved copper concentrations for Quesnel Lake (Figure 19 and Figure 20) and Quesnel River (Figure 21) would likely have been present at concentrations substantially lower than 30-d BC WQG. The modelling results indicate that copper was mainly present as copper carbonate ($CuCO_3$) (generally greater than 80% of the dissolved concentration), with minor percentages of copper hydroxide ($CuOH^+$ and $Cu(OH)_2$) and free ionic copper (Cu^{2+}) present.

Given the copper species most bioavailable to aquatic life are free ionic copper and copper hydroxides, the speciation modelling suggested that only a small percentage of dissolved copper concentrations would have been bioavailable for direct uptake from the water by organism in Quesnel lake and Quesnel River. The majority of dissolved copper, as represented by the fraction passing a 0.45-µm filter, would have been present as copper carbonate that is less bioavailable for direct uptake compared to free ionic copper.

4.2.4 Post-Event Toxicity Testing Program

The evaluation of water quality impacts in the receiving environment discussed in Section 4.2.2focussed on changes in water chemistry and exceedance of BC WQGs based on an examination of individual COPCs; however, in reality these substances exist in a complex mixture. Although the most common form of interaction among contaminants is additive, it is possible that more-than-additive (synergistic) or less-than additive (antagonistic) interactions are operable. In addition to monitoring water quality following the event, MPMC also initiated a toxicity testing program where water samples taken from the receiving environment were subject to a battery of standard laboratory acute and sub-lethal tests using sensitive plant, invertebrate, and fish test species. The program provides the strongest evaluation of the bioavailable fraction as it is a direct measure of effect using water from the site and sensitive test species representing primary producers, primary consumers, and secondary consumers.

4.2.4.1 Initial Toxicity Testing (August to September 2014)

Minnow (2015) reported on a total of 53 toxicity tests using six different species that were carried out on water samples collected in August and September 2014 from Polley Lake (POL-2, POL-6), Quesnel Lake (QUL-66), and the Quesnel River (QUR-1). These tests also included testing of the discharge from Polley Lake to Hazeltine Creek (HAD-1, HAD-2). Quesnel Lake water samples were taken from the monitoring station closest to the source of event-related inputs at the mouth of Hazeltine Creek.

The following standard toxicity tests were included in the post-event toxicity testing program:

- 96-h acute lethality to rainbow trout (*Oncorhynchus mykiss*);
- 48-h acute lethality to *Daphnia magna*;
- 7-d survival and growth of fathead minnow (*Pimephales promelas*);
- 7-d survival and reproduction of *Ceriodaphnia dubia*;
- 7-d growth inhibition in the aquatic plant *Lemna minor;* and,
- 72-h growth inhibition in the alga *Pseudokirchneriella subcapitata*.

Overall, the results of this testing in the weeks following the event indicated no toxicity that could be attributed to the elevated concentrations reported for some metals. This finding supports the chemistry results of the water quality monitoring program that consistently reported lower concentrations of dissolved metals compared to total metals, as well as the copper speciation described above. As discussed in Section 4.2.2.3 dissolved forms are understood to be more bioavailable for direct uptake from water by aquatic organisms compared to particulate metals.

In a relatively small number of tests (9 of 53 tests) some responses were noted. These were typically observations of impaired reproduction in *C. dubia* exposed to turbid deep water samples from Quesnel Lake. The observed effects were not considered to be related to metal concentrations; however, recommendations were made by Minnow (2015) to undertake confirmatory resampling and retesting to verify the observed responses and examine potential causes.

4.2.4.2 Follow Up Toxicity Testing (November 2014 to February 2015)

Subsequent water samples collected from November 2014 to February 2015 were subject to the following sub-lethal toxicity tests:

- 7-d survival and reproduction of *C. dubia* on filtered (0.45 µm) and unfiltered samples to examine the influence of suspended solids.
- 7-d survival and growth of rainbow trout; and,
- 7-d survival and growth of fathead minnow.

Fish Toxicity Testing

No impacts on survival and growth of fathead minnows and rainbow trout were observed for water samples collected from Polley Lake (P2 surface, POL-4), Quesnel Lake (QUR-66 surface and depth), and Quesnel River (QUR-1; Table 4-4).

An early life stage test (embryo-alevin) with rainbow trout was carried out using water samples regularly collected from the Quesnel River (QUR-1) between November 25 and December 22, 2014. The water samples were collected to coincide with egg availability which also coincided with the period of greatest turbidity in Quesnel River. There were no reported adverse effects on the survival or normal development of rainbow trout eggs exposed to the water through to hatching of the alevin stage (MPMC 2015). Similar results were observed when the test was repeated with water samples collected from December 10, 2014 to January 7, 2015 (MPMC unpublished data). These results suggest that the increase in turbidity in the Quesnel River after turnover of Quesnel Lake was unlikely to have an effect on incubating salmonid eggs in the river.

Invertebrate Toxicity Testing

No impacts on *C. dubia* survival were observed in water samples collected from Polley Lake (P2 surface, POL-4), Quesnel Lake (QUR-66 surface and deep), and Quesnel River (QUR-1; Table 4-4). Likewise no impacts on *C. dubia* reproduction were observed in samples from Polley Lake (P2 surface, POL-4), Quesnel River in January and February 2015, and from filtered samples from Quesnel Lake.

Reproductive effects were reported for unfiltered samples, taken mainly at depth from Quesnel Lake close to the Hazeltine Creek mouth, but no effects were observed for the corresponding filtered samples suggesting that exposure to suspended particulate matter in the samples may have resulted in a reproductive test response in this sensitive invertebrate. Two unfiltered samples taken from Quesnel River in November and December 2014 also showed a reproductive test response (Table 4-4) that coincided with rising turbidity at the station sampled (QUR-1).

Table 4-4: Summary of Post-event Surface Water Toxicity Testing (November 2014 to February 2015) (unpublished MPMC data)

Test Type	Station	Sample Date	LC50 (% v/v)[a] (Median Lethal Concentration)	IC25 (% v/v)[a] (25th Percentile Inhibitory Concentration)	IC50 (% v/v)[a] (Median Inhibitory Concentration)

4.2.5 Summary

Observed Changes in Water Quality

Following initial screening of water quality using BC WQGs, including total and dissolved forms of relevant parameters, COPCs were identified for the receiving environment (Table 4-2). Changes in concentrations of COPCs (i.e., suspended particulate matter, metals, and phosphorus) were evaluated for stations selected to be representative of Polley Lake, Quesnel Lake, and Quesnel River. Temporal and spatial changes throughout the post-event period from August 2014 to April 2015 were examined in relation to applicable BC WQGs.

Post-event changes in COPCs over time are summarized in Table 4-5. Post-event concentrations of COPCs were typically only elevated at depth until the beginning of lake turnover. Following turnover when the lakes were mixed, concentrations of some COPCs at depth decreased, but increased near the surface as a result of the mixing throughout the water column. The most recent sampling (up to April 2015) indicates that concentrations of all identified COPCs have decreased to below BC WQGs or are within the range of pre-event conditions, with the exception of total copper in Quesnel Lake. Although total copper concentrations showed a substantial decreasing trend over the post-event period, concentrations in one or more samples from at least one of the representative stations in Quesnel Lake remain elevated above BC WQGs for the protection of aquatic life. Concentrations of total copper and the other COPCs measured following the event, from August 2014 to April 2015, were below BC WQGs for other relevant uses; i.e., wildlife, and drinking water sources[12].

[12] Molybdenum concentrations at the representative stations were below BC WQGs for the protection of aquatic life and drinking water

Table 4-5: Summary of Post-Event Changes of Identified Contaminants of Potential Concern in the Receiving Environment over Time at Representative Stations

Study Area	Contaminant of Potential Concern	Event to Lake Turnover (August 2014 to November 2014)		Lake Turnover to Last Sampling Event (November 2014 to April 2015)		Last Sampling Event (up to April 2015)	
		Surface	Deep	Surface	Deep	Surface	Deep

	Dissolved Copper	● (green)		● (orange)		● (green)	

Notes:
n/a: Not applicable; only surface water samples were collected from Quesnel River.
(a) Dissolved metal form shown, but results are summarized because the total metal form was identified as a COPC.
(b) Concentrations exceed the BC WQG, but are comparable to pre-event conditions (Section 4.2.2).
(c) Concentrations began to increase above the 30-d BC WQG range (based on the range of hardness) in October 2014.
● (green) = Concentrations are below BC WQG(s) at representative stations
● (orange) = Concentrations exceed the maximum and/or 30-day BC WQG in one or more samples from at least one representative station.

Evaluation of Copper Bioavailability

Based on comparison to BC WQGs for the protection of aquatic life and pre-dam failure conditions, total copper concentrations in Quesnel Lake have increased and exceed the BC WQGs (Table 4-5). The BC WQGs for the protection of aquatic life are a useful tool to identify chemicals in water that may cause adverse effects, but they are conservative in their derivation and should not be used for making remedial decisions. Ideally, more direct measures of toxicity should be used that take into consideration the mixture of contaminants and other parameters in the water. The findings of toxicity testing with water samples using three trophic levels of test species covering primary producers, primary consumers and secondary consumers sampled throughout the post-event period together with the several geochemical lines of evidence provided a more realistic assessment of potential impact of changes in water quality to aquatic life.

Observed changes in metal concentrations in the receiving environment due to the event were unlikely to have resulted in adverse effects on aquatic organisms in consideration of the following lines of evidence.

- A toxicity testing program initiated immediately after the event and carried through the post-event period indicated that receiving environment waters were not acutely toxic to sensitive plant, fish, and invertebrate species. Sub-lethal, long-term effects were not reported for sensitive plant, fish, and invertebrate species, with the exception of a reproductive test response in some samples related to suspended matter in the samples and not water chemistry.
- Although total metals concentrations were elevated above provincial guidelines for the protection of aquatic life for some metals, dissolved concentrations were substantially lower and generally did not exceed provincial guidelines, or decreased to below guideline in the period following the event (with the exception of copper). These guidelines are derived from laboratory-based toxicity tests where exposure concentrations are measured in solutions characterized by low levels of suspended matter and total and dissolved concentrations are similar. The application of WQGs to total concentrations under turbid conditions prevalent during the post-event period is therefore conservative.
- Dissolved forms of copper in Quesnel Lake and Quesnel River would likely have been dominated by copper carbonates with a minor proportion of copper present in the free ion form (Cu^{2+}) that is readily bioavailable for direct uptake from the water by organisms. Copper carbonates by comparison are not readily bioavailable for uptake.

The WQIA relied on comparisons to provincial water quality guidelines, waterborne toxicity testing and water quality speciation modelling. These lines of evidence have limited consideration of metal uptake via the dietary exposure route[13], but tend to be focussed on direct waterborne exposure. The potential for metal uptake via waterborne and dietary exposure routes by aquatic organisms in the receiving environment after the event is evaluated in Golder (2015d).

---

[13] With the exception of selenium and molybdenum water quality guidelines.

5.0 INTERIM FINDINGS – WATER QUALITY

This section provides interim conclusions based on the data contained in this report. They are interim because the post-event environmental studies are still in progress.

Changes in water quality observed in Polley Lake, Quesnel Lake, and Quesnel River due to the event mainly related to elevated levels of particulate matter suspended in the water column. Over time the suspended particulates settled out in the receiving environment and the available data suggest that levels of particulate matter are no longer of concern in the receiving environment. Suspended solids settled out more quickly following the event compared to the finer particulates measured by turbidity that remained elevated at depth in Quesnel Lake until lake turnover in November.

Concentrations of metals measured in the receiving environment immediately following the event through to April 2015, were not of potential concern with regards to drinking water sources or wildlife, with the exception of molybdenum in Polley Lake that was no longer of potential concern by April 2015 and unlikely to have posed a risk to wildlife based on considerations provided in Swain (1986). Although elevated immediately after the event in Polley and Quesnel Lakes with respect to BC WQGs for the protection of aquatic life, total concentrations of several metals decreased over the post-event period such that by April 2015, only total copper was elevated in Quesnel Lake. Post-event water quality monitoring continues.

Based on comparison to the BC WQG for the protection of aquatic life and pre-dam failure conditions, total copper concentrations in Quesnel Lake increased following the event. The BC WQGs for the protection of aquatic life are a useful tool to identify chemicals in water that may cause adverse effects, but they are conservative in their derivation and should not be used for remediation purposes. Ideally, more direct measures of toxicity should be used that take into consideration the mixture of contaminants and other parameters in the water. The findings of toxicity testing with water samples using three trophic levels of test species covering primary producers, primary consumers, and secondary consumers sampled throughout the post-event period, together with the several geochemical lines of evidence, provided a more realistic assessment of potential impact of changes in water quality to aquatic life. These findings indicate that, although there were measured changes in water quality, the evidence available to date does not indicate that the event resulted in toxicity in the water column. We note that this report is an interim report and that additional studies remain ongoing or are planned.

6.0 UNCERTAINTY ASSESSMENT

The impact assessment involved the compilation and assessment of pre- and post-event water quality data to evaluate changes in water quality in the study areas as a result of the event. It is appropriate to identify areas of uncertainty for the ongoing development of water quality monitoring downstream of the Mount Polley mine.

The main uncertainties are summarized and discussed below in Table 6-1.

Table 6-1: Uncertainty Assessment for the Water Quality Impact Assessment

Uncertainty Source / Assumption	Degree of Uncertainty	Under/ Over Estimate of Impact	Rationale
Assessment stations selected in each study area were representative of the water quality in that area.	Low	Neutral	Routinely monitored stations in each study area were targeted. Reasonable spatial coverage was targeted in Quesnel Lake including two stations located close to the mouth of Hazeltine Creek and the source of breach-related inputs to Quesnel Lake.
Post-event monitoring during the winter months at some stations was limited due to logistical and safety concerns. The available data are assumed to provide a reasonable characterization of conditions at and following fall turnover in Quesnel Lake and downstream in Quesnel River.	Moderate	Neutral	The coverage of assessment stations per area was such that winter monitoring data were available within each study area during the lake turnover events and from December to February, although at a reduced frequency.
Evaluation of metal parameters was primarily based on the comparison of dissolved metal concentrations to BC WQGs.	Low	Neutral	As discussed in Section 3.3 (Identification of COPCs), this assumption is supported by the available science that shows that dissolved concentrations are bioavailable for uptake by aquatic biota. An evaluation based on the total concentration, especially under turbid conditions, would over-estimate the potential for adverse effects and not provide useful or realistic input to the Restoration and Remediation Strategy.
Dissolved metal concentrations in their entirety were bioavailable to aquatic biota.	Moderate	Over Estimate	The identification of relationships between dissolved copper and turbidity and suggestions by Tetra Tech (2015) that laboratory-measured TSS is missing some fine-grained material, suggests that the dissolved samples may contain some fine particulates. Metals associated with those particulates may not be bioavailable for uptake and so the potential for toxicity may be over-estimated.
Post-event mercury data were limited after early September 2014. Mercury was frequently reported below method detection limits that are above the BC WQG.	Low	Neutral	Mercury was monitored for approximately one month following the event when concentrations would have been the highest. Limited data collected after September support the expectation that mercury concentrations decreased over time. Further monitoring would confirm this expectation.
Background metals data were not available for Quesnel Lake and limited data were available for Quesnel River.	Low	Neutral	The identification of metal COPCs for Quesnel Lake and Quesnel River generally relied on a comparison to BC WQGs that are conservative and intended to be applied province-wide.

Uncertainty Source / Assumption	Degree of Uncertainty	Under/ Over Estimate of Impact	Rationale
Pre-event surface water quality data were used as received from the source (i.e., MPMC or BC MoE).	Low	Neutral	Reported values were assumed to be accurate and representative of the study areas given known data quality assurance/quality control programs.
Pre-event surface water quality data were characterized by a range of method detection limits, based on data availability.	Low	Neutral	COPC identification primarily focus on screening to BC WQGs for the protection of aquatic life, using upper-limit (maximum and 95^{th} percentile) post-event concentrations. This was considered to be a conservative screening approach that would not have been heavily influenced by a pre-event condition defined by method detection limits.
Interaction of contaminant mixtures will not result in effects greater than estimated through the use of BC WQGs.	Low	Neutral	The assessment evaluated water quality parameters individually; however, in reality they exist in a mixture in each study area environment. Although the most common form of interaction among contaminants is additive, it is possible that more-than-additive (synergistic) or less-than additive (antagonistic) interactions are operable. Toxicity testing of water samples collected from the study areas addresses uncertainty related to mixture effects, as discussed in Section 4.2.4.

Notes:
MPMC = Mount Polley Mining Corporation; BC MoE = British Columbia Ministry of Environment; COPC = Contaminant of Potential Concern; BC WQG = British Columbia Water Quality Guideline; RRS = Rehabilitation and Remediation Strategy; TSS = total suspended solids.

7.0 CLOSURE

We trust that this report provides sufficient information for your present needs. If you have any questions, please do not hesitate to contact the undersigned at 604-296-4200.

9.0 GLOSSARY

Term	Definition
95th Percentile	The number in a distribution such that 95% of the values in the distribution are less than or equal to the number and 5% of the values are greater than the number.
Abrading	The action by which suspended solids wear away or erode fish tissues.
Acute	A stimulus severe enough to rapidly induce an effect; in aquatic toxicity tests, an effect observed in 96 hours or less is typically considered acute. When referring to aquatic toxicology or human health, an acute effect is not always measured in terms of lethality.
Additive	When two or more substances acting in combination produce a total effect that is equivalent to the sum total of the individual effects of each substance.
Adsorbed	Refers to atoms, ions or molecules that are adhered or bonded to a surface.
Adverse effect	An effect that results in a negative impact or is considered undesirable.
Alkalinity	A measurement (expressed in mg/L of calcium carbonate) of the capacity of water to neutralize acids. The concentration is measured based on the presence of naturally available bicarbonate, carbonate, and hydroxide ions.
Antagonistic	Refers to an effect resulting from the opposing effects of two substances or actions.
Anthropogenic	Human-related, often referring to an activity, development or disturbance on the landscape.
Bioaccumulation	The accumulation of a substance in the tissues of an aquatic organism through exposure to water and diet.
Bioaccumulation factor	The ratio of the concentration of a substance in tissue to its concentration in water or the diet, when the organism could have accumulated the substance through either media.
Bioavailability	The portion of a substance or chemical that is immediately available for uptake by organisms. Bioavailability of different substances can change over time.
Bioconcentration	The accumulation of a substance in the tissues of an aquatic organism through exposure to water only (does not include dietary uptake).
Bioconcentration factor	The ratio of the concentration of a substance in tissue to its concentration in water.
Biomagnification	Increasing tissue concentrations of a substance solely through uptake from food such that the tissue concentrations increase at each trophic level in the food web.
Biomass	Refers to the mass of biological material, including plants, animals and decaying organic matter, present within a particular habitat, area or ecosystem at any one time.
Biota	Plant and animal life found in a region, watercourse or waterbody.
Chlorophyll *a*	A photosynthetic pigment found in plants responsible for the conversion of inorganic carbon and water into organic carbon. The concentration of chlorophyll *a* is an indicator of algal concentration.
Chronic	The development of adverse effects after extended exposure to a given substance. In chronic toxicity tests, the measurement of a chronic effect can be reduced growth, reduced reproduction or other non-lethal effects, in addition to lethality. Chronic should be considered a relative term depending on the life span of the organism.

Term	Definition
Conductivity	A measure of the ability of water to carry an electrical current. This measurement is directly related to the amount of positively (cations) and negatively (anions) charged ions in the water and can be correlated with the concentration of total dissolved solids.
Confluence	Refers to the location at which two watercourses join and become one stream or river.
Constituent	An individual chemical, property, or measurement in water (e.g., aluminum, chloride, total dissolved solids)
Contaminant of Potential Concern (COPC)	A chemical that is emitted or released into the environment and poses a potential risk of exposure to humans or ecological receptors.
Contiguous	Refers to two items or entities that are touching or side-by-side.
Creek	Branch of or small tributary to a river.
Detritus	Small particles of organic matter produced by the breakdown and decay of plant and animal matter.
Diatom	A type of planktonic algae. Diatoms are generally unicellular and have cell walls that contain silica.
Dimictic	Refers to lakes that mix from top to bottom twice a year; mixing occurs in spring and fall.
Discharge	The volumetric rate of flow of water in a watercourse at a specified point, expressed in units of m^3/s or equivalent.
Dissolved organic carbon (DOC)	The dissolved portion of organic carbon in water. It is comprised of humic substances and partly degraded plant and animal materials.
Dissolved oxygen (DO)	The amount of free oxygen dissolved in water, usually expressed in milligrams per litre (mg/L), parts per million (ppm), or percent of saturation (%). Adequate concentrations of dissolved oxygen are required by fish and other aquatic organisms.
Downstream	Away from the source of a river or stream.
Dyke	A long wall or embankment built to prevent flooding.
Epilimnetic	Refers to the upper layer of water within lakes that develop a thermocline.
Erosion	The wearing away of the land surface by running water, wind, ice, or other geological agents.
Euphotic zone	In an aquatic environment, it is the uppermost layer of water that receives sufficient sunlight to promote photosynthesis.
Eutrophic	Excessive growth of algae or other primary producers in a stream, lake, or wetlands as a result of large amounts of nutrient ions, especially phosphate or nitrate.
Far-field	An area far removed from the zone of influence.
Field duplicate	A second water sample that is collected at the same place and time as the original water sample.
Fjord lake	A lake formed by the action of receding glacial ice.
Freshet	Flow conditions resulting from the melting of snow and ice in spring.
Fry	A young, newly hatched fish that has used up its yolk sac and has started active feeding.

Term	Definition
Geochemistry	The chemistry of the composition and alterations of solid matter such as sediments or soil.
Habitat	The physical space within which an organism lives, and the abiotic and biotic entities (e.g., resources) it uses and selects in that space.
Hardness	A measure of the mineral content of a water sample; magnesium- and calcium-containing compounds contribute to water hardness. Water samples with high and low mineral contents are referred to either hard or soft, respectively.
Humic	Describes substances that contribute to the natural organic matter found in water.
Hydraulic residence time	Time required for a volume of water equivalent to the lake volume to be discharged from a lake (lake volume divided by daily river discharge).
Hypoxic	Refers to a watercourse, waterbody or water sample that has low levels of dissolved oxygen. Generally this refers to water conditions where dissolved oxygen is less than 5 mg/L or in the range of 1 to 30% saturation.
In situ	In place, i.e., measured in the field.
Ion	A molecule or atom that has a net positive or negative electric charge due to an uneven number of electrons and protons.
Ionic strength	An expression of the ionic charge in a sample of water. The greater the concentration of ions in a sample, the greater the ionic strength.
Lethality	Refers to the ability of a toxicant or action to cause death.
Limnological	Pertaining to the study of open fresh and more rarely saline waterbodies, specifically lakes and ponds (both natural and manmade), including their physical, chemical, and biological properties.
Lowest Observed Effect Concentration (LOEC)	Refers to the lowest concentration of a substance that is found to cause an adverse effect to the growth, development or lifespan of a test organism.
Macroinvertebrates	A group of animals that lack a spinal cord and are large enough to be seen with the naked human eye.
Mean	Arithmetic average value in a distribution.
Median	A single statistical value used to characterize a series of data values. Half of the data values are larger than the median value, and half of the data values are less than the median value.
Mesotrophic	Describes the trophic status of a watercourse or waterbody with moderate nutrient enrichment; total phosphorus concentrations are generally between 10 and 20 micrograms per litre.
Metals	Any of a class of substances (including many chemical elements) which are in general lustrous, malleable, fusible, ductile solids and good conductors of heat and electricity.
Metalloids	Any element intermediate in properties between metals and non-metals. A metalloid element has the form or appearance of a metal.
Method detection limit	Refers to the lowest concentration of a substance (e.g., metal, nutrient) that can be measured with 99% confidence that the measured concentration is not equal to zero (i.e., the substance is present in the sample media).
Mid-field	An area located a moderate distance from the zone of influence.

Term	Definition
Mitigation	The elimination, reduction or control of the adverse environmental effects of a project, including restitution for any damage to the environment caused by such effects through replacement, reclamation, compensation, or any other means.
Near-field	An area located within or near the zone of influence.
Nutrients	Elements or chemicals essential to growth or repair of organic bodies, including carbon, oxygen, nitrogen, phosphorus, and silica.
Oligotrophic	Trophic state classification for lakes characterized by low productivity and low nutrient inputs (particularly total phosphorus).
Ore	A type of mineral or rock that contains relatively large concentrations of metals or other economically valuable substances.
Orthophosphate	A phosphate-containing salt or ester.
Parameter	A particular physical, chemical, or biological property that is being measured.
pH	The negative log of the concentration of the hydronium ion. It is a measure of the acidity or alkalinity of all materials dissolved in water, expressed on a scale from zero (0) to 14, where seven (7) is neutral, values below seven are acidic and values over seven are alkaline.
Plankton	Microscopic aquatic organisms (tiny plants [phytoplankton] and animals [zooplankton]) free-floating and suspended in the water column.
Plume	Describes a discharge in terms of its shape, size and/or direction of movement within the receiving environment, namely surface water.
Productivity	A measure of the biomass produced by an aquatic system.
Redox	Refers to reduction and oxidation reactions in which electrons are transferred between atoms.
Remediation	The process of removing, reducing or neutralizing the adverse effects a hazardous material has on the environment.
Risk assessment	Process that evaluates the probability of adverse effects that may occur, or are occurring on target organism(s) as a result of exposure to one or more stressors.
Sediment	Solid material that is transported by, suspended in, or deposited from water. It originates mostly from disintegrated rocks; it also includes chemical and biochemical precipitates and decomposed organic material, such as humus. The quantity, characteristics and cause of the occurrence of sediment in streams are influenced by environmental factors. Some major factors are degree of slope, length of slope soil characteristics, land usage and quantity and intensity of precipitation.
Significant	A term used in statistics to describe the likelihood that a given outcome of a tested difference or similarity is in fact due to some relationship, rather than chance.
Seiche	A type of long-wavelength wave that occurs as a result of some disturbance within waterbody that is relatively closed-off from the outside environment. Long waves resonate outward to the boundaries of the waterbody, and then resonate back inward.
Silica	A tough, hard substance found in the cell walls of diatoms.
speciation (metal)	The form of a metal occurring in water.
Sonde instrument	An instrument used to measure water quality (e.g., dissolved oxygen, pH, conductivity, temperature) in situ.

Term	Definition
Specific conductivity	Represents the ability of a water sample to conduct an electrical current. Waters with higher concentrations of dissolved salts will have a greater specific conductance. The measurement is corrected based on temperature.
Standard deviation	An expression of the spread or variation of a collection of data values or measurements.
Standard error	The standard deviation of a calculated statistic.
Sub-watershed	A smaller portion of a watershed containing a drainage area, which is connected to the larger portion by a single channel.
Supernatant	A liquid layer overlying a more solid layer.
Synergistic	When two or more substances acting in combination produce a total effect that is greater than the sum total of the individual effects of each substance.
Tailings	The substances and materials remaining after metals and/or other economically valuable substances are removed from ore.
Temporal	Occurring over time.
Thermal stratification	Refers to the process by which layers of water having different temperatures form within a waterbody.
Thermocline	In thermally stratified waterbodies, the thermocline is the transitional zone between the upper layer of warmer water and the lower layer of cooler water.
Total dissolved solids (TDS)	The dissolved matter found in water that is comprised of mineral salts and small amounts of other inorganic and organic substances.
Total phosphorus	A measurement of particulate and dissolved phosphorus and phosphate molecules in water.
Total suspended solids (TSS)	The amount of suspended substances in a water sample. Biotic (e.g., plankton) and abiotic (e.g., silt) solids that can be removed from a water sample by filtration.
Toxic	Refers to a substance, dose, or concentration that is harmful to a living organism.
Toxicant	A substance that elicits a toxic, harmful effect in a living organism.
Toxicity	The inherent potential or capacity of a material to cause adverse effects in a living organism.
Turbidity	The degree of clarity in the water column or in a water sample; turbidity can be used as a surrogate measure of the amount of suspended particulate matter in a waterbody.
Turnover	A seasonal process that involves the mixing of upper and lower layers of water within a lake; mixiing of water masses is depended on water temperature and density.
Uptake	The process by which a chemical crosses an absorption barrier and is absorbed into the body.
Water quality	A measure of concentrations of contaminants, or naturally occurring minerals, in water. Lower concentrations of a particular contaminant generally lead to better water quality.
Watershed	The area drained by a river or stream.

APPENDIX A

Pre-Event Surface Water Quality

MEMORANDUM

March 26, 2014

TO: Jordana van Geest, Golder Associates Ltd.

FROM: Katie McMahen, Mount Polley Mining Corporation

RE: Baseline/Background Water Chemistry Data Search for the MPMC PEEIAR

TABLE OF CONTENTS

1 INTRODUCTION

As per the letter sent to Dale Reimer, General Manager of Mount Polley Mining Corporation (MPMC) by the British Columbia Ministry of Environment (BC MoE) on February 20, 2015, the Post-Event Impact Assessment Report (PEEIAR) for the Mount Polley Tailings Storage Facility (TSF) breach of August 4, 2014 is to "incorporate all available baseline/background data and compared to monitoring data results".

This summary document provides an overview of available baseline/background water chemistry data that has been sourced for the water quality section of the PEEIAR.

2 BASELINE/BACKGROUND WATER CHEMISTRY DATA PURSUED

Baseline/background (herein referred to as "pre-event") water chemistry data for the following sub-areas of the area impacted by the breach were sourced to be incorporated into the PEEIAR:

- The Mount Polley TSF;
- Polley Lake;
- Hazeltine Creek ;
- Edney Creek Mouth;
- Quesnel Lake; and
- Quesnel River.

3 SUMMARY OF SOURCES CONTACTED AND DATA OBTAINED

3.1 Mount Polley Mining Corporation

MPMC has a large dataset of baseline and pre-event data available, as follows:

- TSF supernatant (site E1, 1997 – 2014);
- Polley Lake (sites P1 and P2, 2001 – 2014, and 1995 – 2014 for select parameters);
- Hazeltine Creek (site W7, 1990 – 2014); and
- Edney Creek downstream of the confluence with Hazeltine Creek (1995 – 2014).

The water chemistry of these locations was also characterized in detail in the *Technical Assessment Report Mount Polley Mine Discharge of Treated Water to Polley Lake* and accompanying *Aquatic Environmental Description* (Minnow, 2014).

Based on the long data records and regular sample collection frequencies by MPMC staff, this data is considered to be sufficiently comprehensive for these areas that only a search for Quesnel Lake and Quesnel River pre-event data was further pursued.

MPMC also has a single sample from Quesnel Lake at the end of the North Arm that was taken on May 14, 2012. This sample location is spatially very distant from the West Arm where the post-event sampling program took place. Given that the water chemistry in the North Arm potentially has different influencing sources and factors; based on this, and that it is a single sample, these results will not be incorporated as pre-event data.

3.1 Local Consultants

A number of local consultants who have worked in the Likely and Quesnel Lake area were contacted to inquire whether they had any pre-event data or if they could recommend other sources of pre-event data.

3.1.1 Richard Holmes, RPBio

Richard Holmes of Cariboo Envirotech Limited was contacted by email on December 11, 2014, to inquire if he was aware of any available Quesnel Lake or Quesnel River water chemistry data. In his response on December 12, 2014, Mr. Holmes indicated that Fisheries and Oceans Canada (DFO) had a water sampling program at the Quesnel River Research Centre (then called the Quesnel River Hatchery) during its years of operation (1981 – 1995). The Hatchery did some water quality monitoring at that time as part of an effluent discharge permit from the MoE. His other recommendation was to contact other local consultants Norm Zirnhelt and Rob Dolighan.

3.1.2 Norm Zirnhelt, RPBio

Norm Zirnhelt of Environmental Quality Consulting was contacted by email on December 11, 2014, to inquire if he was aware of any available Quesnel Lake or Quesnel River water chemistry data. In his response on December 11, 2015, Mr. Zirnhelt indicated that MoE did a study of Horsefly Bay in Quesnel Lake and recommended contacting Chris Swan and Kym Keogh of MoE. He also recommended contacting Rob Dolighan, another local consultant who previously worked for the DFO.

3.1.3 Rob Dolighan, RP Bio

Rob Dolighan was contacted by email on December 11, 2014, to inquire if he was aware of any available Quesnel Lake or Quesnel River water chemistry data. In his response on December 12, 2014, Mr. Dolighan reiterated Mr. Zirnhelt's comment that MoE had collected water quality data related to a study of nutrient loading from the Horsefly River. He also mentioned that the Institute of Ocean Sciences had collected some chemistry and physical limnology data and suggested Svien Vagle as a contact with this organization. His final recommendation was that majority of historic data would be with the DFO research group at Cultus Lake who have collected limnological data from Quesnel Lake since 1985. Daniel Selbie was provided as a DFO contact.

3.2 Regulatory Agencies

3.2.1 BC Ministry of Environment

Chris Swan (MoE Environmental Impact Assessment Biologist), Kym Keogh (MoE Environmental Impact Assessment Biologist) and Gabriele Matscha (MoE Environmental Impact Assessment Section Head) were all contacted by email on December 11, 2014, to inquire if they had any historic Quesnel Lake or Quesnel River water chemistry data. On February 5, 2015, Kym Keogh provided available data. For Quesnel Lake, this dataset is large (approximately 650 samples from the West Arm of Quesnel Lake primarily focused around Horsefly Bay), but consists only of nutrient data. For Quesnel River, this dataset consists of 43 samples taken at Likely between 1972 and 1988, which were analysed for nutrients and several other parameters, but not representing what is considered a typical “full suite” sample in current times; limited metals data is available (for example, 13 dissolved copper and two total copper results).

Results from 12 samples taken in Quesnel Lake by the University of British Columbia (UBC) Oceanography Department on September 9, 2003 were previously sourced from MoE by Minnow Environmental Ltd. (Minnow) for inclusion in the document *Mount Polley Mine Technical Assessment for a Proposed Discharge of Mine Effluent* (MPMC, 2009). Neither Minnow nor MoE were able to provide further details on these samples, such as sample location coordinates and data quality information, in response to requests from MPMC in 2015. The data also does not include dissolved metals, and method detection limits exceeded the BC Water Quality Guidelines for a number of parameters, including arsenic, boron, cadmium, chromium, cobalt, copper, lead, selenium and silver. Given this, and the lack of data quality and location information, the data was not selected for use as baseline/background data in the PEEIAR.

Due to the apparent lack of baseline data for Quesnel Lake and Quesnel River, an additional request was sent to BC MoE (Chris Swan and Kym Keogh via email) on March 9-10, 2015, for available reference data from any creeks or rivers flowing into Quesnel Lake. Results for select parameters from samples of Horsefly River were provided on March 16, 2015, for 352 samples taken from 2006 to 2014. This data was not recommended for use in baseline comparison, because it reflects a different catchment area with different land uses and environmental conditions.

On March 10, 2015, at the request of MPMC, Leigh-Ann Fenwick (MoE Mount Polley Environmental Project Manager) send a request for available data to the Environmental Working Group, a group composed of relevant agencies, First Nations, and stakeholders that was assembled to provide feedback to MPMC on breach response measures and monitoring. One response was received from David Weir (BC Ministry of Forests, Lands and Natural Resource Operations (MFLNRO) Water Section Head), indicating that he had some data.

3.2.1 BC Ministry of Forests, Lands and Natural Resource Operations

On March 13, 2015, Dave Weir reviewed MFLNRO files on Polley Lake and Hazeltine Creek with Katie McMahen (MPMC). All available data were related to hydrology, and no water chemistry data were found.

3.2.2 Fisheries and Oceans Canada

Dr. Dan Selbie, Head of the Lakes Research Program, Science Branch, Salmon and Freshwater Ecosystems was contacted on December 11, 2014, to inquire if he was aware of any available Quesnel Lake or Quesnel River water chemistry data. In his response on December 15, 2014, Dr. Selbie provided a paper on limnological data from the 1985-1990 study of Quesnel Lake (Nidle et al., 1994) which provides the only comprehensive information DFO has on the West Arm of Quesnel Lake, to the best of his knowledge. He also recommended that there may be some water quality monitoring data associated with the Quesnel River Hatchery Facility when it was in operation. The abstract of the Nidel et al. (2004) study is as follows:

> "Results of a limnological investigation of Quesnel Lake are presented. Ten stations were sampled for a variety of physical, chemical and biological variables. Stations were sampled six or seven times each year during 1985-1988 and 1990. Summarized data for each station and date are presented along with selected vertical profiles of *in vivo* fluorescence and temperature."

This paper provides background nutrient and physical data for Quesnel Lake; however, data for metals and certain physical parameters including turbidity, specific conductance and dissolved oxygen, are not available as part of this data set. This data was not used as baseline data because more recent nutrient data was available from BC MoE.

Svein Vagle from the Institute of Ocean Sciences was contacted via email on December 15, 2014, to inquire if he was aware of any available Quesnel Lake or Quesnel River water chemistry data. In his response on December 18, 2014, he indicated that he was only aware of some unarchived nutrient data that would take some time to review. This nutrient data was not pursued, as relatively comprehensive nutrient data for Quesnel Lake was provided by Dr. Selbie.

A search of the Waves Database on January 22, 2015, for the search terms "Quesnel Lake" and "Quesnel River" yielded 24 and 58 results, respectively; however, no water chemistry data was found in these documents.

3.2.3 Interior Health

Rob Birtles of Interior Health was contacted by email on December 11, 2014, to inquire if he was aware of any available Quesnel Lake or Quesnel River water chemistry data. Mr. Birtles indicated that we was not aware of any Interior Health recreational water quality data for Quesnel Lake, and said he would search for any historic raw (pre-treatment) drinking water data. In an email sent March 9, 2015, Mr. Birtles confirmed that no historic data was available.

3.2.4 Environment Canada

Elaine Irving, Senior Environmental Scientist with Golder Associates had a phone conversation on March 6, 2015, with Jessica Ingram, Water Quality Monitoring and Surveillance, Pacific and Yukon, Environment Canada regarding federal water quality data for Quesnel Lake and Quesnel River from the last 15 years. Ms. Ingram indicated that according to the Canada-British Columbia Water Quality Monitoring Agreement signed in 1985, Environment Canada does not have any water quality data additional to those data provided by the province of BC.

3.3 Regional Researchers

3.3.1 University of British Columbia

Dr. Bernard Laval of UBC was contacted on December 11, 2014, to inquire if he was aware of any available Quesnel Lake or Quesnel River water chemistry data, as he has been actively researching flow patterns and physical limnology of Quesnel Lake for more than a decade. In his response on December 19, 2014, Dr. Laval provided references to some of his students' Master's theses:

- The Heat Budget of Quesnel Lake (Potts, 2002); and
- Mixing processes from CTD profiles using a lake-specific equation of state: Quesnel Lake (James, 2001).

Two of Dr. Laval's publications were also sourced:

- Wind-driven Summertime Upwelling in a Fjord-type Lake and its Impact on Downstream River Conditions: Quesnel Lake and River, British Columbia, Canada (Laval et al., 2008); and
- The joint effects of riverine, thermal, and wind forcing on a temperature fjord lake: Quesnel Lake, Canada (Laval et al., 2012).

These papers provide valuable pre-event data on flow patterns and physical parameters, but do not include water chemistry data beyond physical parameters (temperature and specific conductance); for this reason the data is not being used in the PEEIAR water quality section.

3.3.1 University of Northern British Columbia

Sam Albers, Facility Manager of the University of Northern British Columbia (UNBC) Quesnel River Research Centre (QRRC) was contacted by email on January 8, 2015, to inquire if he was aware of any available Quesnel Lake or Quesnel River water chemistry data. In his response on January 8, 2015, Mr. Albers provided the QRRC publication list and a list of literature that the QRRC has compiled relevant to the area. In reviewing the documents listed in these resources, and in a review of papers, books, and documents in the QRRC "library" on January 22, 2015, no relevant water chemistry data was encountered.

An online search of the UNBC library was also completed using the key words "Quesnel Lake" and "Quesnel River" and 49 and 35 results were found, respectively; however, no water chemistry information that had not previously been obtained through other search avenues was found.

4 SUMMARY OF DATA SOURCED

MPMC has an extensive pre-event water chemistry data set for the TSF supernatant, Polley Lake, Hazeltine Creek, and the mouth of Edney Creek. This data will constitute pre-event (baseline/background) data used in the PEEIAR for these locations.

After contacting known local environmental consultants, relevant regulatory agencies, and regional research groups, minimal pre-event water chemistry data was found for Quesnel Lake and Quesnel River. Available pre-event data sourced that will be incorporated into the water quality section of the PEEIAR is:

- 43 samples from the Quesnel River at Likely analysed for limited parameters, with the most recent sample being greater than 25 years ago (MoE).
- Nutrient data for the West Arm of Quesnel Lake from 352 samples taken from 2004 to 2006, primarily focused around Horsefly Bay, just east of Cariboo Island (MoE).

Table 1 provides a summary of the search for pre-event water chemistry data for use in the PEEIAR and Table 2 provides a detailed summary of the pre-event data that was considered for use in the PEEIAR.

Source	TSF	Hazeltine Creek	Polley Lake	Quesnel River	Quesnel Lake	Comments
MPMC	✓	✓	✓	✗	✓	- Includes data collected by Minnow Environmental Inc. - Extensive data for TSF, Hazeltine Creek, and Polley Lake - Only a single sample from Quesnel Lake (end of North Arm)
MoE	Did not search for data beyond MPMC dataset (considered sufficient to characterize pre-breach conditions for these areas)			✓	✓	- Nutrient data only for Quensel Lake - Data also provided for Horsefly River (Quesnel Lake inflow) - Limited metal data and the most recent sample was >25 years ago
MFLNRO				✗	✗	- Hydrology data only
DFO				✗	✓	- Quesnel Lake data is from 1985 - 1990 and includes only nutrient and general chemical data (no metal data). - Search of DFO Waves data base yielded no results with water chemistry data.
Institute of Ocean Sciences				✗	✗	Some unarchived nutrient data available, but not pursued.
Environment Canada				✗	✗	Do not collect data since the Canada-British Columbia Water Quality Monitoring Agreement was signed in 1985.
Interior Health				✗	✗	
Norm Zirnhelt				✗	✗	Recommended contacting MOE and Rob Dolighan.
Rob Dolighan				✗	✗	Recommended contacting MOE, DFO, and the Institute of Ocean Sciences.
Richard Holmes				✗	✗	Recommended contacting MOE, Norm Zirnhelt and Rob Dolighan.
UNBC				✗	✗	Search of UNBC library yielded no results with water chemistry data (that had not already been found from other sources).
UBC				✗	✓	- Physical parameters (CTD cast data). - Water quality data without sample location or data quality information. No total metals data and poor method detection limits (above BC Water Quality Guidelines) for multiple parameters.

Table 2. Summary of pre-event water chemistry data considered for use in the water quality section of the MPMC TSF breach PEEIAR

Source: MPMC

Notes:

Summary statistics were calculated and presented as follows:

- Minimum, Maximum, and Median were calculated using absolute values; that is, when the summary statistic corresponded to a non-detect (ND) value in the dataset, then the method detection limit (MDL) was reported.
- Mean, Standard Deviation (SD), Standard Error (SE), and 95th percentile were calculated by substituting 0.5*MDL for any ND values. Therefore, it is possible that 95th percentile was equal to 0.5*MDL.
- Mean, SD, and SE were not calculated for parameters with greater than 50% non-detect values.
- 95th percentile was not calculated for parameters with greater than 95% non-detect values.

(a) Calculated values are equal to the highest method detection limit.

< = less than; MDL = method detection limit; % = percent; µS/cm = microSiemens per centrimetre; mg/L = milligrams per litre; °C = degrees Celcius; $CaCO_3$ = calcium carbonate; nc = not calculated; NTU = nephelometric turbidity units; N = nitrogen; P = phosphorus.

Source: MPMC

Notes:

Summary statistics were calculated and presented as follows:

- Minimum, Maximum, and Median were calculated using absolute values; that is, when the summary statistic corresponded to a non-detect (ND) value in the dataset, then the method detection limit (MDL) was reported.
- Mean, Standard Deviation (SD), Standard Error (SE), and 95th percentile were calculated by substituting 0.5*MDL for any ND values. Therefore, it is possible that 95th percentile was equal to 0.5*MDL.
- Mean, SD, and SE were not calculated for parameters with greater than 50% non-detect values.
- 95th percentile was not calculated for parameters with greater than 95% non-detect values.

(a) Calculated values are equal to the highest method detection limit.

< = less than; MDL = method detection limit; % = percent; µS/cm = microSiemens per centimetre; mg/L = milligrams per litre; °C = degrees Celcius; $CaCO_3$ = calcium carbonate; nc = not calculated; NTU = nephelometric turbidity units; N = nitrogen; P = phosphorus.

Source: BC MoE

Notes:

Summary statistics were calculated and presented as follows:

- Minimum, Maximum, and Median were calculated using absolute values; that is, when the summary statistic corresponded to a non-detect (ND) value in the dataset, then the method detection limit (MDL) was reported.
- Mean, Standard Deviation (SD), Standard Error (SE), and 95th percentile were calculated by substituting 0.5*MDL for any ND values. Therefore, it is possible that 95th percentile was equal to 0.5*MDL.
- Mean, SD, and SE were not calculated for parameters with greater than 50% non-detect values.
- 95th percentile was not calculated for parameters with greater than 95% non-detect values.

< = less than; MDL = method detection limit; % = percent; µS/cm = microSiemens per centrimetre; mg/L = milligrams per litre; °C = degrees Celcius; $CaCO_3$ = calcium carbonate; nc = not calculated; NTU = nephelometric turbidity units; N = nitrogen; P = phosphorus.

MEMORANDUM

March 26, 2014

TO: Jordana van Geest, Golder Associates Ltd.

FROM: Katie McMahen, Mount Polley Mining Corporation

RE: MPMC Post-Event Water Quality Monitoring Program Summary

TABLE OF CONTENTS

1 INTRODUCTION

In response to the Mount Polley Tailings Storage Facility (TSF) breach, which occurred on August 4, 2014, Mount Polley Mining Corporation (MPMC) initiated a water quality monitoring program in the downstream environments of Polley Lake, Hazeltine Creek, Edney Creek, Quesnel Lake, and Quesnel River. This memorandum summarizes the post-event water quality monitoring program and discusses the program's objectives, key changes to program elements, and the changing environmental, safety, and logistical considerations which influenced the program.

The monitoring program was initially developed and managed by representatives from Imperial Metals Corporation (Jack Love, R.P.Bio) and Minnow Environmental Inc. (Pierre Stecko, R.P.Bio), with support from MPMC (Colleen Hughes, EP and Katie McMahen, P.Ag) and Cariboo Environmental Quality Consulting (Norm Zirnhelt, P.P.Bio). SNC Lavalin Inc. (Trevor McConkey, P.Ag, Erik Jancicka, P.Chem, and Cliff Robinson, R.P.Bio) transitioned into managing the program in mid-August, with support from MPMC and Golder Associates Ltd. (Lee Nikl, R.P.Bio). Starting on December 20, 2014, full program management transitioned to MPMC.

This program was continually adapted based on factors including, but not limited to, monitoring results, recommendations for additional sampling from the British Columbia Ministry of Environment (BC MoE), and seasonal conditions, such as lake turnover. Weekly summaries of the water quality monitoring program were submitted to BC MoE and published on the Imperial Metals Mount Polley Updates website. These weekly reports included:

- Water quality monitoring planned and completed;
- Deviations from the program (such as supplemental monitoring or stations missed due to unsafe boating conditions); and
- Changes to the monitoring program, and rationale for any changes.

The subsequent sections summarize the development and evolution of the post-event water quality monitoring program from August 6, 2014 to February 28, 2015.

2 INITIAL RESPONSE AND PROGRAM DEVELOPMENT

Immediately following the TSF breach, the initial response included four main components as described below. These evolved into key elements of the water quality monitoring program. Samples were shipped to ALS Laboratory daily with emergency (less than one day) turnaround time until August 12, 2014, when it was adjusted to priority (24 hour) turnaround time. Additional details on sampling methods, sample handling, and Quality Assurance/Quality Control measures are referenced in separate documents from SNC Lavalin Inc. and MPMC (SNC, 2015; MPMC, 2015).

Unless otherwise specified, samples were analysed for a full suite of parameters, which includes total and dissolved metals (except mercury), anions, nutrients, and dissolved organic carbon. Supplemental monitoring of other parameters is discussed in Section 8.

2.1 Plume Delineation

On August 6, 2014, water quality monitoring in Quesnel Lake commenced to track the extent and movement of the plume of suspended solids that entered the lake as a result of the debris flow from the TSF. On the first day of sampling, this consisted of monitoring at the surface only to allow samplers to cover a larger area. Subsequently field parameter profiles and samples throughout the water column were taken, as it was discovered that the plume was at depth (contained within the hypolimnion). Profiles could only be conducted to 30 metres in depth and did not include turbidity initially until equipment could be rented or bought from Hoskin Scientific; these orders were rushed.

The limitations of these monitoring methods were recognized, and EBA-Tetra Tech were contracted to carry out larger scale transects of conductivity, temperature, and turbidity profiles, as well as conduct limnological and hydrodynamic investigations.

2.2 Implementation of Routine Monitoring at Key Locations

2.2.1 Hazeltine Creek and Polley Lake

Initially, due to geotechnical concerns over the stability of the “plug” at the outflow of Polley Lake, access to Hazeltine Creek and boating on Polley Lake were not permitted under the safe work procedures developed by MPMC under guidance from the BC Ministry of Mines. For this reason, Hazeltine Creek was not initially included in the monitoring plan, and monitoring of Polley Lake was limited to shoreline samples around the perimeter (three sites were monitored daily from August 8 -21, 2014, at which point sample frequency was reduced to weekly).

2.2.2 Quesnel Lake

In the first ten days after the breach, routine monitoring at key near-field and downstream stations commenced in addition to investigative plume delineation monitoring. Approximately daily surface monitoring was carried out at QUL-20 and QUL-22, and approximately daily profiles and samples throughout the water column were carried out at QUL-18 and QUL-26. By late August, while some supplemental sampling to monitor the plume was still ongoing, a routine monitoring program was implemented for Quesnel Lake from Cariboo Island to the Quesnel River (Table 1). Water quality monitoring stations are shown in the map included as Attachment 1.

Table 1 Initial Quesnel Lake routine monitoring program

Monitoring Type	Frequency	Stations
Surface	Daily/every two days	QUL-20*, QUL-18, QUL-23**
Surface + depth	Every two days	QUL-2, QUL-21, QUL-22, QUL-66, QUL-79

*surface only (profile done to confirm lake was fully mixed)

**shallow station (profile or depth samples not possible)

2.2.3 Quesnel River

The start of Quesnel River at the outlet of Quesnel Lake in Likely, BC was identified as a key location to monitor water passing out of Quesnel Lake to the downstream environments. Station QUR-1 was established at the Quesnel River Research Centre on August 6, 2014, and was monitored daily until December 23, 2014. On August 12, 2014, an ISCO automatic sampler was installed at QUR-1, and it sampled three times per 24 hours on evenly spaced intervals. The ISCO samples were only analysed for total metals, dissolved metals, anions, and turbidity, but daily full suite grab sampling continued through this period. A YSI EXO sonde was also installed at QUR-1 on August 12, 2014; this instrument was deployed to measure field parameters (including pH, temperature, specific conductance, dissolved oxygen, and turbidity) every 15 minutes, and is still in place. Data is downloaded weekly, at minimum.

2.3 Monitoring of Residential Drinking Water Quality

A number of residents on Quesnel Lake and upper Quesnel River draw drinking water from the lake or river. On August 7, 2014, water quality monitoring was initiated to respond to human health concerns regarding consumption of the water. Initially this program involved surface samples in residential areas, including Likely, Winkley Creek, Mitchell Bay, and near the junction of Quesnel Lake's east and north arms. By mid-August, the program expanded to include samples near residential water intakes (at depth off docks or from a boat) and tap samples at individual houses, as requested by residents. The majority of requests were met by the end of August, but sampling continued into October and included re-visiting some residents when requested. Sample results were shared with residents.

2.4 Implementation of Water Toxicity Testing Program

A water toxicity testing program was implemented to assess potential acute or chronic toxicity conditions in areas downstream of the TSF. Testing at Quesnel River (QUR-1), Polley Lake, and Quesnel Lake (near the Hazeltine Creek mouth) commenced August 6, 9, and 21, 2014, respectively. Phase 1 of this program included ongoing monitoring at these stations until September 30, 2015. When all of the toxicity test results were available, they were reviewed by Pierre Stecko, R.P. Bio (Minnow Environmental Inc.), and MPMC began carrying out recommendations for Phase 2 of monitoring at these same locations on November 19, 2015. It is anticipated that this second phase of testing will be completed by the end of April 2015. A more detailed summary of this program is provided in the memorandum from Minnow Environmental Inc. to MPMC entitled "Summary and Interpretation of Water Toxicity Tests" and dated January 9, 2015.

3 PUMPING OF POLLEY LAKE

To manage accumulation of water behind the “plug” at the south end of Polley Lake (which prevented water from flowing into Hazeltine Creek) and to address geotechnical concerns regarding the stability of the “plug”, pumps were installed at the south end of Polley Lake to transfer water around the “plug” into Hazeltine Creek. This system was commissioned on August 10, 2014, and water at the pipe outlet (station HAD-1) was sampled daily from August 10, 2014, until September 2, 2014. Sampling frequency was reduced to weekly until the pumps were removed at the end of November. A second pipeline was commissioned at the end of August, and the outflow (station HAD-2) was sampled four times to confirm consistency with HAD-1. After September 3, 2014, field parameters were taken from HAD-1 and HAD-2 for comparison and if readings were consistent (within 10%), only HAD-1 was sampled to avoid redundancy.

4 IMPROVED ACCESS

At the end of August, further geotechnical investigations and drawing down of Polley Lake water levels through pumping allowed MPMC to amend the Hazeltine Creek safe work procedure to allow restricted access to Hazeltine Creek and boating on Polley Lake. The resulting changes in the monitoring program are outlined in the subsequent sections.

4.1 Polley Lake

On September 9, 2014, weekly monitoring of sites around the perimeter of Polley Lake was replaced with weekly monitoring at four stations (including two stations which were monitored prior to the event) located along the midline of the lake This included field parameter profiles and samples throughout the water column.

4.2 Hazeltine Creek

Investigative monitoring was carried out along the length of Hazeltine Creek starting on August 24, 2014, and routine stations were established at:

- HAC-01 at the outlet of Hazeltine/Edney Creek into Quesnel Lake. This site was sampled daily, (when conditions allowed safe access) until September 25, 2015, when the daily sampling station was moved to station HAC-01a to adjust for lateral channel movement; and
- HAC-05 in Upper Hazeltine Creek at the Gavin Lake Road bridge. This station was sampled weekly until early February when sampling was discontinued due to active rehabilitation and sediment and erosion control work taking place in the area.

Four samples of the water flowing from the TSF breach location to the Hazeltine Creek channel were taken between August 23 and September 11, 2014. Sampling was discontinued because flow from this source was captured into Mount Polley's contact water collection system, which went online on September 4, 2014.

Access to Hazeltine Creek further improved with the construction of new bridges at the Gavin Lake Road and Ditch Road crossings, and as part of post-event hydrology and geomorphology investigations, Manta Eureka 2 continuous monitoring sensors were installed at the Gavin Lake Bridge (HAC-05) and Ditch Road Bridge (HAC-08). From November 5/6-26, 2014, these sensors logged turbidity, temperature, and specific conductance measurements every 30 minutes.

5 PLUME MIGRATION

In mid-September, as the plume migrated east of Cariboo Island in Quesnel Lake, increased monitoring of this area resulted in gradual adjustments to the routine monitoring program. During this period, preliminary findings from EBA-Tetra Tech's monitoring program also became available to help guide the water quality monitoring program. Refinements to the monitoring program included:

- Increased monitoring of the East Basin (east of Cariboo Island).
- Stations were spatially adjusted to monitor the deepest locations in Quesnel Lake (station names for the adjusted locations had an "a" added to them); and
- A sample location was added (QUL-zoo-8), which is the zooplankton monitoring station of the University of Northern British Columbia Quesnel River Research Centre. This station is located at the junction of the east and north arms of Quesnel Lake.

The Quesnel Lake routine monitoring program as of late September is shown in Table 2.

Table 2 Quesnel Lake routine monitoring program, as of late September 2014

Monitoring Type	Frequency	Stations
Surface	Weekly	QUL-20*
Surface + depth	Weekly	QUL-2, QUL-2a, QUL-21, QUL-21a, QUL-22, QUL-18, QUL-31a, QUL-40a, QUL-66, QUL-66a, QUL-119, QUL-Zoo-8
	Twice per week	QUL-40, QUL-79, QUL-87, QUL-120, QUL-112

*surface only (profile done to confirm lake was fully mixed)

6 ONSET OF WINTER CONDITIONS

As winter approached, monitoring of lake turnover in Polley and Quesnel Lakes took place, and was followed by reduction in sampling frequencies to account for unsafe boating conditions, freeze up, and low flow conditions. These adjustments are outlined below. In addition, some equipment that had previously been installed and is not designed to withstand winter conditions was removed, including removal of the ISCO sampler at QUR-1 on October 1, 2014, and removal of the Manata Eureka 2 continuous monitoring sondes from Upper and Lower Hazeltine Creek on November 26, 2014.

6.1 Polley Lake

Polley Lake continued to be monitored through fall turnover (when the thermal stratification of a lake breaks down and the lake becomes fully mixed). Turnover occurred in early November and sampling ended on November 18, 2014. Surface samples were taken at stations POL-4 in December and P2 in January in association with samples collected for toxicity testing. Unseasonably warm winter conditions did not allow typical formation of ice on the lake, and as a result planned under-ice sampling was not completed.

Requested sample turnaround time at the laboratory was adjusted to “regular” status (approximately ten days) in November after the lake had turned over.

6.2 Hazeltine Creek

As more water chemistry data for Hazeltine Creek became available and creek flow rates slowed due to freezing conditions in late November, sampling frequency at HAC-01a was reduced to weekly and the requested laboratory turnaround time was reduced to “regular” status.

6.3 Quesnel Lake

Based on predictions of a Quesnel Lake hydrodynamic model developed by EBA-Tetra Tech, mixing of the turbidity contained in the hypolimnion throughout the entire water column was anticipated as thermal stratification of the lake broke down and fall turnover occurred. As winter conditions made safe boat access to Quesnel Lake monitoring stations less reliable, the monitoring program in late October was streamlined (Table 3) and efforts were made to maintain spatial coverage and frequent monitoring of key locations for fall overturn. Note that stations QUL-120, QUL-112, and QUL-zoo-8 had deeper or shallower alternatives, which were monitored in depending on weather conditions.

Table 3 Quesnel Lake routine monitoring program, as of late October

Monitoring Type	Frequency	Stations
Surface + depth	Weekly	QUL-2a, QUL-18, QUL-21a, QUL-40a, QUL-66, QUL-66a, QUL-112/QUL-112a, QUL-120/QUL-120a, QUL-zoo-8/QUL-zoo-8a
	Twice per week	QUL-79
Time/weather permitting		QUL-2, QUL-20*, QUL-21, QUL-22, QUL-31a, QUL-87, QUL-119

*surface only (profile done to confirm lake was fully mixed)

On October 23-24, 2014, Justin Rogers of EBA-Tetra Tech conducted a site visit to help MPMC develop a procedure for carrying out “casts” instead of manually logging lake profiles, to improve monitoring efficiencies. Implementation of this new procedure in late November allowed for increased data collection in a shorter time period (ideal for winter weather conditions). This resulted in further adjustments to the routine monitoring program, as shown in Table 4.

Table 4 Quesnel Lake routine monitoring program, as of late November

Monitoring Type	Frequency	Stations
Surface + depth	Weekly	QUL-18, QUL-66a, QUL-79, QUL-112/QUL-112a
Profiles only	Weekly	QUL-22, QUL-21a, QUL-18, QUL-66a, QUL-66, QUL-2a, QUL-79, QUL-40a, QUL-120/QUL-120a

This program was maintained through turnover, which occurred in late November in the West Basin and early December in the East Basin. Sampling was discontinued for winter on December 17, 2014. No additional residential monitoring was completed during the turnover period because the lake was fully mixed at turnover, and samples taken in the routine sampling program were expected to be representative of water near residential intakes. MPMC has also been supplying residents who draw water out of the lake with drinking water since the TSF breach occurred.

Supplemental monitoring was completed during unseasonably warm weather in January, with sampling and a profile taken along with planned toxicity testing samples at QUL-66 on January 15, 2015. Profiles were also completed at stations QUL-18, QUL-40a, and QUL-79 on January 22, 2015. Requested sample turnaround time at the laboratory for Quesnel Lake was adjusted to “regular” status in January 2015.

6.4 Quesnel River

Requested laboratory sample turnaround time for Quesnel River was adjusted to “regular” status at the end of December after the lake had turned over, and the sampling frequency was reduced to weekly.

7 LOWER HAZELTINE SEDIMENT AND EROSION CONTROL WORKS

On December 12, 2014, construction of sedimentation ponds in Lower Hazeltine Creek, just upstream of Quesnel Lake, was completed and the ponds were commissioned. Further changes in the monitoring program resulted as follows:

- Station HAC-01a was moved to station HAC-01b, the new outflow channel of Hazeltine and Edney Creek (downstream of the sedimentation ponds and upstream of Quesnel Lake).
- Weekly monitoring of stations upstream of the sedimentation ponds commenced, for comparison with HAC-01b (originally at HAC-09 at the pond inflow, then moved upstream to HAC-08 to avoid influence of Edney Creek, which was also flowing into the sedimentation ponds).
- A YSI EXO sonde was deployed at HAC-01b on January 19, 2015 and continuously monitors field parameters (pH, specific conductance, ORP, temperature, dissolved oxygen, and turbidity), logging data every fifteen minutes.
- On February 15, 2015, Edney Creek flow was diverted from the sedimentation ponds into the reconstructed Lower Edney Creek channel, which joins Hazeltine Creek downstream of the sedimentation ponds. Two new weekly monitoring stations were established: EDC-01 (Edney Creek upstream of the confluence with Hazeltine Creek); and EDC-02 (Edney Creek downstream of the confluence with Hazeltine Creek, upstream of Quesnel Lake).

8 MONITORING OF SPECIFIC PARAMETERS

8.1 Bacteriology

Bacteriology samples for analysis of total coliform bacteria and *E. coli* were taken between August 7, 2014, and August 8, 2014, because sewage from the mine facilities was discharged to the TSF prior to the breach. This monitoring was discontinued when some results from the ambient receiving environment were found to exceed pre-event levels in the TSF, and appeared to be in the typical range for lakes in the region.

8.2 Mercury

Based on historic monitoring and geochemistry of the tailings and rock at the Mount Polley site, mercury was not anticipated to be an issue. However, due to public concern, water sampling for analysis of mercury was conducted until early September. It was discontinued based on results consistently being below ALS Laboratory’s method detection limit.

8.3 Processing Reagents

From October 8-15, 2014, sampling for volatile organic compounds related to mine processing reagents was completed at near-field monitoring stations in Polley Lake, Hazeltine Creek, and Quesnel Lake. This sampling was not continued because results were low level or below laboratory method detection limits. This decision was further supported by results from the Soil Quality Impact Assessment, which indicated that concentrations of related parameters were less than laboratory detection limits in the soil samples targeted for analysis.

8.4 Speciated Chromium

Water sampling for analysis of speciated chromium was initiated the week of October 17, 2014, at stations where chromium exceedances of BC water quality guidelines were observed. This specialized analysis was used to quantify the relative composition of different chromium species in order to apply the species-specific MoE BC water quality guideline for aquatic life.

8.5 Particle Size

To improve understanding of the physical characteristics of the fine particles suspended in Quesnel Lake, advanced particle size analysis was carried out using a Mastersizer at the University of Western Ontario. Samples taken on November 20, 2014, from HAC-01, and QUL-66 (surface and depth), and on November 25, 2014, from QUL-18 (surface and depth) were analysed.

8.6 Chlorophyll *a*

Chlorophyll *a* sampling was conducted at surface monitoring locations on Quesnel Lake September 3-20, 2014. Monitoring was carried out to verify that turbidity of the plume was not associated with algae or other phytoplankton, and to monitor surface chlorophyll *a* levels in areas downstream of the breach to evaluate the impact of the event on algae and phytoplankton. This monitoring did not continue into winter conditions, when these organisms are typically less active.

9 SUMMARY

A map of these stations is included as Attachment 1 (Mount Polley Mine Tailings Storage Facility Breach Water Quality Monitoring Stations). A summary of water quality monitoring completed, including number of samples at surface and depth, number of lake profiles taken, and associated sampling periods is provided in Attachment 2.

1. INTRODUCTION

The objective of this memorandum is to document the field sampling methods and data quality assurance / quality control (QA/QC) measures implemented during the water quality monitoring and sampling program following the Mount Polley Mine (Mine) Tailings Storage Facility (TSF) breach. The following program components are summarized:

- A summary of the QA/QC methods and their implementation;
- A description of field methods used to collect water quality data;
- A summary of the data management systems used; and
- A summary of qualifications of water quality monitoring and sampling team members.

2. QUALITY ASSURANCE / QUALITY CONTROL

The Environment & Water Division of SNC-Lavalin Inc. (SNC-Lavalin) assisted Mount Polley Mining Corporation (MPMC) with the development and implementation of a QA/QC program during the water quality monitoring and sampling program following the TSF breach. SNC-Lavalin staff was directly involved in the field data collection program from August 22, 2014 to November 19, 2014, and with the data management and QA/QC review for sampling dates from August 4, 2014 to December 19, 2014. Quality assurance (QA) included management and technical practices designed to confirm that data were commensurate with the objectives of the water quality program and that data were scientifically tenable. The quality control (QC) included specific data quality objectives (DQOs), statistical assessment of data quality, and corrective measures taken whenever the DQOs were not met.

The following sections detail the QA/QC program implemented during the water quality monitoring and sampling program. The project-specific data integrity and management plan and QA/QC flow chat, Attachment 1, were used as guidance documents during the field sampling program.

2.1. Field Data Collection and Document Control

Water quality data were collected using a range of field sampling and monitoring equipment. Equipment was used in accordance with manufacturer's recommendations and MPMC Standard Operating Procedures and Work Methods, inspected daily, and maintained in good working condition. Calibration information including calibration results, standard solution information, and equipment comments or concerns was recorded on calibration logs for each piece of equipment used during the program. For full equipment methodologies and calibration details, refer to sections 3.1 through 3.3.

Field data related to the water quality program for the Mount Polley TSF breach were collected and tracked using multiple field forms developed or adapted for use on this project. Forms were used for field data collection, including water sample collection details, lake profile data collection, equipment calibration, and daily observations tracking. Field data and samples were collected by staff from SNC-Lavalin, MPMC, Minnow Environmental Inc., Cariboo Environmental Quality and Tetra Tech EBA. Field forms were reviewed by SNC-Lavalin staff daily to confirm that records were filled out in full, and were consistent with other information submitted. Field forms were filed and saved electronically according to date and area of interest. Individual samples were tracked using spreadsheets to record the locations of samples, frequency of sampling, duplicate and blank sample information, sample shipping information, laboratory correspondence, and QA/QC issues. Examples of field forms and tracking forms are included in Attachment 2. Details related to sample procurement and handling are summarized in section 3.5.

2.2. Analytical Laboratory

A Canadian Association for Laboratory Accreditation Inc. (CALA) accredited laboratory, ALS Environmental (ALS) of Burnaby, BC, was used to analyze the water samples. Water samples submitted were tracked for adherence to laboratory sampling and analysis protocols, including hold times, sample containers, preservatives, detection limits, and approved methodology. Details regarding laboratory protocols are available from ALS upon request.

The laboratory QA/QC program included the analysis of laboratory method blanks, laboratory sample duplicates, surrogate recovery, and chemical spikes. The laboratory method blank analysis was used to detect interferences or impurities introduced by laboratory equipment, reagents, or solvents. Surrogate recovery was analyzed by spiking samples with known quantities of surrogate chemicals that have similar chemical properties to the parameters being analyzed. The reported recovery provided an indication of the analytical method accuracy. Chemical spikes were conducted by adding known concentrations of the analyte of interest to a sample to evaluate the effects of the sample matrix on the analytical method. The analysis of selected samples in duplicate was used to evaluate the reproducibility of the analytical method.

Results of the laboratory's QC performance (standards, spike recoveries, etc) were requested to be included in the analytical results reports, and were reviewed to confirm results were within acceptable limits. Instances of non-conformity to laboratory QA limits required additional analysis to confirm the quality of the initial result.

Prior to sample submission, chain-of-custody (CoC) forms were prepared and checked by field staff to ensure sample IDs, sample time, hold time, preservative and sample storage temperatures were correctly entered. To avoid transcription errors that may be introduced during laboratory internal process, electronic CoC forms were used for samples collected after September 24, 2014.

A sample tracking sheet was used to record field and laboratory related information, including sample IDs and dates, sample shipped and received dates, laboratory report and sample IDs, and QA/QC notes in laboratory sample receipt confirmation (SRC) forms and lab reports.

Upon receipt of each SRC from the laboratory, details were compared against CoCs including sample IDs and dates, recording of all requested analyses, and sample integrity or hold time issues. Follow up correspondence and corrective actions were initiated in the case of any discrepancies.

Upon receipt of each certificate of analysis (COA) from the laboratory, analyses completed were checked against CoCs. A thorough review of the laboratory QA/QC notes was also completed to confirm that analytical results were reported within acceptable quality control limits. Re-analyses were requested if any results reported outside of the DQO were potentially due laboratory sample handling and procedures.

Laboratory method detection limits (MDLs) for all parameters analyzed, as well as counts of the number of samples for which each MDL was reported, are included in Attachment 3. Elevated MDLs were noted during data review and checked for consistency against the laboratory's comments on each COA. Elevated MDLs were primarily due to adjustments for required dilution as a result of sample turbidity. If a reported MDL exceeded a comparison criterion, the result was footnoted during data tabulation.

2.3. QA/QC Samples

Quality control samples collected during the water quality sampling program included blind field duplicate samples, equipment blanks, filter blanks, field blanks, deionized (DI) water blanks and trip blanks.

- Blind field duplicate samples were samples collected at the same location and time by the same sampler and using the same sampling procedure and equipment. Duplicate samples were used to check the reproducibility of field and laboratory procedures, and to indicate sample heterogeneity.
- Equipment blanks contained DI water that was transferred to the appropriate sample container after passing through the decontaminated field sampling equipment. Equipment blanks were used to assess whether sampling equipment was introducing a source of potential contamination.
- Filter blanks contained DI water that had passed through the filter used to collect samples for dissolved metals analysis. Filter blanks were used to assess whether the filters being used were introducing a source of potential contamination.
- Field blanks contained analyte-free water prepared in bottles by ALS that was exposed to the atmosphere and ambient conditions at a specific sampling location by opening the bottles. These blanks were used to quantify the potential exposure to contaminants from airborne or other sources potentially associated with ambient conditions at the sampling location.
- DI water blanks contained DI water transferred to the appropriate sample container. These blanks were used to determine the quality of the DI water and to confirm its suitability for use in decontamination procedures.
- Trip blanks contained analyte free water prepared in bottles by ALS that traveled to and from the site or sampling location without breaking the seal of the bottle. Trip blanks were used to assess the potential for contamination from sample handling, shipping, and laboratory analytical procedures.

The target frequencies of duplicate samples and blanks that were adopted for the QA/QC program are summarized in Table A below. As the sampling program proceeded, the observed quality and reproducibility of data as well as the size of the data set supported performance-based decisions to reduce the frequency of duplicate and blank samples. Initial and final target frequencies are indicated in Table A.

Table A: QA/QC Duplicate and Blank Target Frequencies

QA Sample Type	Initial Target Frequency	Final Target Frequency	Applicable Parameters
Blind Field Duplicates	Every 10 samples	Every 10 samples	All parameters
Equipment Blanks	Every 20 samples or per equipment	Weekly	All parameters
Filter Blanks	Weekly	Weekly	Dissolved Metals
Field Blanks	Every 20 samples	Weekly (rotate sample areas)	All organic parameters
DI Water Blanks	Weekly	Monthly	Total Metals
Trip Blanks	Weekly	Weekly (rotate sample areas)	Volatiles only

A summary of duplicate and blank frequencies achieved during the program is included in section 2.4.

2.3.1. Data Quality Objectives

In order to assess blind field duplicate results relative to DQOs, SNC-Lavalin calculated the practical quantitation limit (PQL) which was defined as five times the laboratory method detection limit (MDL). For analytes in blind field duplicate sets where concentrations were above the PQL, the relative percent difference (RPD) was calculated as described below. Because analytical error increases substantially when results approach the PQL, RPDs were not considered meaningful and were not calculated if one or both concentrations in a duplicate set were below the PQL.

RPD values were calculated using the following equation:

$$RPD\ (\%) = \frac{|X_x - X_y|}{\bar{X}} \times 100$$

Where X_x= the concentration of the original sample

X_y= the concentration of the blind field duplicate sample

The acceptance criteria for RPDs between blind duplicate samples for water parameters were defined as 1.5 times the laboratory RPD criteria for this program, as summarized in Table B below.

Table B: Duplicate Sample RPD Acceptance Criteria

Analyte Group	RPD Acceptance Criterion
Metals	30%
Inorganics	30%
Organics	45%
Other parameters	1.5 X Laboratory RPD

2.4. Summary of QA/QC Sample Results

A summary of frequencies and results for QA/QC samples collected during the program is provided below.

2.4.1. Duplicate and Blank Sample Frequencies

The frequencies of duplicate and blank samples that were collected during the water sampling program are indicated in Table C below.

Table C: QA/QC Duplicate and Blank Achieved Frequencies

QA Sample Type	Quesnel Lake	Polley Lake	Hazeltine Creek	Program Total
Regular Samples	1,354	128	154	1,636
Blind Field Duplicates	103 (7.6%)	14 (11%)	12 (7.8%)	129 (7.9%)
Equipment Blanks	29	3	0	32 (average 1.6 / week)
Filter Blanks	17	0	0	17 (average 0.9 / week)
Field Blanks	32	3	7	42 (average 2.1 / week)
DI Water Blanks	10	0	0	10 (average 2 / month)
Trip Blanks	9	2	6	17 (average 0.9 / week)

2.4.2. Relative Percent Differences

Blind duplicate sample sets for which RPD values exceeded the DQO are summarized in Attachment 4, and are separated by type of RPD issue and by sampling area.

As outlined in Attachment 4, RPD exceedances were generally attributable to the following causes:

- Laboratory related QA/QC issues;
- Potential contamination from field sampling equipment (i.e., high equipment blanks); and
- Poor repeatability between the field duplicate samples.

Once an RPD exceedance was identified, the associated results were subsequently compared to comparison guidelines, and the laboratory was contacted if one or both concentrations were greater than comparison guidelines. For RPD exceedances due to laboratory related issues, corrective action was initiated by reanalyzing the batch of affected samples.

2.4.3. Blank Sample Issues

Analytical results indicated that all filter blanks, field blanks, DI water blanks and trip blanks were within the specific DQOs.

Some equipment blank issues were identified during the sampling program, as listed in Attachment 4. These blanks contained concentrations of some analytes greater than the PQL, which was defined as the DQO for blank samples. Field samples collected on these days were flagged as potentially contaminated by sampling equipment. Some of the analytical results for these samples were also flagged as having RPD issues, as listed in Attachment 4. Equipment blank issues were subsequently resolved through review of methods (including more thorough equipment decontamination), field audits and discussions with field staff.

2.4.4. Laboratory QA Results

In addition to the RPD issues identified in Attachment 4, several samples were noted as having dissolved metals concentrations greater than total metals concentrations. SNC-Lavalin followed up with the lab on these results, but a root cause was not determined.

3. FIELD MONITORING AND SAMPLING METHODOLOGY

The sections below outline methodologies implemented for the collection of field data and samples during the water quality field program.

3.1. Monitoring and Sampling Locations

Station locations were navigated to and recorded in the field using a Garmin handheld GPS unit. Coordinates for each new station were recorded on field forms and saved in a tracking spreadsheet. Coordinates for new stations were programmed into other onsite field GPS units for future sampling visits. Coordinates were used to generate drawings showing station locations to date, which were subsequently verified by field staff. Station locations were uploaded into SNC-Lavalin’s database and associated with the relevant samples at each station.

Sample ID nomenclature used prefixes that were related to the subject study area from which the samples were collected. Sample prefixes for each area included: QUR (Quesnel River), QUL (Quesnel Lake), POL (Polley Lake), HAC (Hazeltine Creek), and HAD (Hazeltine Creek Discharge). The sample IDs were uploaded to the SNC-Lavalin database.

3.2. Water Quality Monitoring and Column Profiling

3.2.1. YSI EXO1 and YSI EXO2

YSI EXO sondes were used to collect water quality data which were stored on the sonde units themselves or the handheld, depending on the application, and then transferred to the EXO handheld unit, and/or transferred to an onsite MPMC computer. Data were collected using user-replaceable sensors which measured up to six different parameters at one time. The parameters measured are outlined in sections 3.2.1.1 through 3.2.1.9. A qualified representative from the YSI EXO vendor, Hoskin Scientific, was contracted to come to the Mine for a day to carry out a training workshop on calibration, use, care, and maintenance of this equipment.

The YSI EXO units can be used to collect data using multiple logging methods. During the course of the water quality monitoring program, data were collected in four different ways. Initially, water quality data were collected by recording information from the YSI EXO handheld unit directly onto field forms by hand.

After approximately one month, the water quality team switched to manual logging data on the handheld, which involved lowering the sonde to a desired depth and capturing the data point on the handheld unit. This generated a data set for a specific location at different depths which was subsequently uploaded to an onsite MPMC computer.

The casting method was also used to collect data, which involved adjusting the settings on the sonde to collect data at specific time intervals and lowering the sonde into the water at a rate of approximately 1 metre per second (m/s). During the water quality monitoring program, the sonde was programmed to collect data every 0.25 seconds. The procedure for this data collection method involved placing the boat approximately 50 m upwind of the desired station(to account for drift), determining the depth of the water using depth detectors, and lowering the sonde at a rate of 1 m/s, stopping 2 m above the bottom. The sonde was then retrieved at the same rate. Parameters were recorded during both the down-cast and the up-cast. Depth was monitored using a metered rope attached to the sonde. This procedure was completed twice, creating two sets of data which could then be compared for data variability and reliability. If the sonde made contact with the bottom during the first cast (because depth to bottom was too deep to be determined using a depth detector), it was cleaned by performing a surface water rinse and wiping the sonde with a Kimwipe®. During the casting process, boat operators attempted to hold the boat in position; however, if significant drift occurred during the cast, the operator slowly manoeuvred the boat until the line was less than 10 degrees from vertical. Drift was recorded on field sheets. Data collected using these methods were uploaded to an onsite MPMC computer at the end of each day.

The final logging method, continuous monitoring, involved permanently installing a YSI EXO sonde at a specific location within a body of water and programming it to record data at specific time intervals. This method was only used at one location, QUR-1, located in Quesnel River. Data was collected every 15 minutes for the duration of the water quality sampling program, and was downloaded to an onsite MPMC computer and reviewed approximately once per week. At this location, readings of temperature, specific conductivity, pH, dissolved oxygen (DO) and turbidity were also manually recorded onto field forms or captured on the YSI EXO handheld daily when samples were being taken. The continuous logging sonde was cleaned approximately monthly and data were compared to laboratory results, with sensors being calibrated as necessary based on the results of these comparisons.

3.2.1.1. Depth Measurements

The YSI EXO2 sonde and one of two YSI EXO1 sondes were used to measure water depth in metres (m) which was verified in the field manually by counting metre marks along the length of the deployment cord. The other YSI EXO1 sonde did not have depth capabilities, and depth was measured manually when using this sonde. When performing the manual logging method using the YSI EXO1, depth measurements were recorded on the field forms and then added to the electronic data set by hand, and subsequently checked for QA/QC.

3.2.1.2. Temperature

The YSI EXO1 and YSI EXO2 units were fitted with temperature sensors which recorded the temperature of the water in degrees Celsius (^{o}C). According to the manufacturer, temperature sensors do not require calibration or maintenance.

3.2.1.3. Specific Conductivity

Specific conductivity is a measure of a solution's ability to conduct electricity, adjusted for the temperature. Measuring the specific conductivity gives an indication of the ionic content in a solution and is closely linked to the total dissolved solids within a solution. The YSI EXO units were fitted with specific conductivity sensors which measured in units of micro-Siemens per centimetre (µS/cm). Checks of the sensors were conducted at the start and end of each day using a standard solution of 1,413 µS/cm. Specific conductivity sensors were calibrated weekly, as per manufacturer's recommendations, or when necessary based on the results of the daily checks. Calibration and daily check information including date, time, temperature, cell constant value, YSI QC score, and user initials were recorded on calibration forms for each YSI EXO unit.

3.2.1.4. pH

The pH of water is a measure of how acidic or basic it is and ranges from 0 (acidic) to 14 (basic). pH is a measure of the relative amount of free hydrogen and hydroxyl ions in the water. The YSI EXO units were fitted with pH sensors which were calibrated daily using standard solutions of pH 4, pH 7 and pH 10 as per manufacturer's recommendations. End of day checks were also conducted to document drift over the course of a day. Calibration and daily check information including date, time, temperature, YSI QC score, standard solutions used, and user initials were recorded on calibration forms for each YSI EXO unit.

3.2.1.5. Dissolved Oxygen

DO is a measure of the total free, non-compound oxygen present in water and is an indicator of water quality which can affect aquatic life. The YSI EXO units were fitted with dissolved oxygen sensors which measured the concentration of dissolved oxygen in water in units of milligrams per litre (mg/L) and percent air saturation.

Sensors were calibrated daily in the field at the sample area to account for changes in barometric pressure. Calibration information including date, time, temperature, pre and post percent saturation, and user initials were recorded on calibration forms for each YSI EXO unit or in the field notes.

3.2.1.6. Oxidation-Reduction Potential

Oxidation-reduction potential (ORP) can affect the chemical (ionic) form of elements and compounds, which may influence their behaviour in the environment. ORP levels are measured in millivolts (mV), and range from -2,000 mV to +2,000 mV. The YSI EXO units were fitted with ORP sensors which estimated ORP based on the total dissolved oxygen concentrations in the water.

ORP sensors were checked and calibrated approximately monthly, using a standard solution of 240 mV. Calibration and check information including date, time, temperature, standard solution, pre and post ORP values, QC score, and user initials were recorded on calibration forms for each YSI EXO unit.

3.2.1.7. Turbidity

Turbidity is a measure of the clarity of water. YSI EXO units were fitted with turbidity sensors which measured the turbidity of water by measuring the amount of light that is scattered by suspended particles in the water column. Turbidity readings were recorded in Formazin turbidity units (FNU) or Nephelometric Turbidity Unit (NTU).

Checks were conducted on the sensors at the start and end of each day using standard solutions of 0 FNU, 12.4 FNU and/or 124 FNU, or comparisons with a calibrated La Motte turbidity meter. Turbidity sensors were calibrated as necessary, when the results of the daily checks indicated instrument drift. Calibration and daily check information including date, time, temperature, standard used, pre and post standards values, and user initials were recorded on calibration forms for each YSI EXO unit.

3.2.1.8. Total Algae and Chlorophyll

Total algae concentration is a measure of the total algal biomass within a unit of water, including planktonic algae and cyanobacteria. Algae concentrations can affect water quality and ecosystem function by reducing nitrogen and carbon concentrations and by depleting dissolved oxygen. The YSI EXO units were fitted with total algae sensors which measured both chlorophyll a and levels of blue-green algae using optical sensors.

Calibration was conducted by using DI water to zero the sensor and using the factory default calibration slope. This method of calibration provided relative data only; algae results were used as a guide to measure fluctuations in algal concentration throughout the water column, rather than as definitive values.

3.2.2. LaMotte 2010 and 2020 Portable Turbidity Meters

The LaMotte turbidity meters are portable devices used to measure the turbidity of water, in units of FNU or NTU. The LaMotte meters can measure turbidity ranging from 0 to 4,000 FNU/NTU by measuring the amount of light that is scattered from suspended particles in the water column. Calibration of LaMotte units was conducted daily, at a minimum, according to manufacturer's recommendations, using standard solutions of 0 NTU, 1 NTU, and 10 NTU.

During the course of the water quality sampling program, the calibrated LaMotte turbidity meters were periodically used as a reference measurement to confirm the validity of the YSI EXO turbidity values. Values were recorded manually onto field forms for each sample location, as well as in the calibration logs for each YSI EXO unit.

3.2.3. WTW Portable Handheld Meter

A WTW portable handheld meter (WTW) was used to measure the conductivity, pH, and DO in water. The WTW was used during the course of the water quality sampling program to collect data from Polley Lake surface, Hazeltine Creek and the Hazeltine Creek Discharge area. Readings were recorded manually onto field forms for each sample location.

Calibration of the WTW pH probes was conducted daily using solutions of pH 7 and pH 10 for pH calibration, and post check were completed at the end of the day. Conductivity probes were calibrated weekly using a 1,413 µs/cm standard. Calibration information including date, time, temperature, standard solution information, calibration results, and user initials were recorded on calibration forms for each WTW unit.

3.2.4. Secchi Disk

A Secchi disk is a 20 cm diameter disk with alternating black and white quadrants which is used to measure the clarity of water. Secchi disks at the end of a rope marked in meters were lowered into the water on the shady side of the boat. Depths were recorded when the disk was no longer visible, and again when the disk reappeared. The average of these two readings was recorded as the "Secchi depth" at each location, and was considered a relative measure of water clarity. Secchi depths were recorded at each non-shoreline station on Quesnel Lake and Polley Lake during each monitoring and sampling event. Surface conditions which may have affected visibility were recorded at each station, including ripples, wind conditions, and relative brightness of the sun. A dedicated observer was responsible for collecting Secchi depths each day, in order to minimize the variability in readings between stations.

3.3. Water Sampling

The following sections outline the methods implemented for the collection of water samples and submission for laboratory analysis. Sampling methods were based on MPMC Standard Operating Procedures and Work Methods and SNC-Lavalin Preferred Operating Procedures, which are generally based on the BC Field Sampling Manual.

For the specific water sample collection methods outlined below, general procedures were implemented, including but not limited to:

- Wearing clean nitrile gloves when collecting samples and switching gloves between each sample.
- The use of clean and decontaminated sampling equipment. Equipment was cleaned daily performing a DI water rinse and by rinsing with surface water at each location between samples.
- The use of laboratory approved bottles for each specific parameter. Bottles were certified clean, supplied by ALS, and shipped to MPMC upon request.
- Performing a triple rinse, using sample water, of laboratory supplied 1 liter plastic sample bottles.
- The use of laboratory approved preservatives for parameters that required field preservation. Preservatives were measured by ALS Laboratory for correct volume, labeled, and supplied to MPMC upon request.

- The use of laboratory approved syringes and 0.45 µm filter disks when collecting samples which required field filtering (dissolved metals). Syringes and filter disks were certified clean, supplied by ALS Laboratory, and shipped to MPMC upon request. Field filtering involved removing the plunger portion of the syringe, attaching the filter disk to the tip, and collecting water in the chamber of the syringe. The plunger was then used to push water through the filter disk and into the sample bottle. A new syringe and filter was used for each sample collected.

- Ensuring proper labeling of each sample bottle including sample ID, client, date, parameter, and preservative was complete and accurate.

- Maintaining sample temperatures below 4^{o}C by storing samples in coolers with ice packs while in the field and during shipping and in refrigerators overnight.

3.3.1. Manual Grab Sampling

Manual grab sampling was used to collect samples of surface water, and involved manually filling laboratory approved bottles for each sampling parameter at the surface of the water, using extension tools to hold the bottles as required.

3.3.2. Kemmerer and Van Dorn Samplers

Kemmerer and Van Dorn water bottle samplers were used to collect water samples from discrete depths below the surface. Although slightly different in shape and size, both water bottle samplers were made from similar materials (acrylic tube with silicone seals on either end), and were operated using the same general principles. Both water bottle samplers were attached to a marked rope. The seals were propped open and the unit was lowered into the water, allowing the water to flow in and out of the tube at either end. Once the unit was at the desired depth, a metal messenger weight was wrapped around the rope and slid down the length of the rope. As the messenger contacted the Kemmerer or Van Dorn sampler, the end seals were released and the tube snapped shut, capturing the water at that specific depth. The water sample was then retrieved to the boat and water was released into the appropriate sample containers through a small spout on the side of the unit. Both units were decontaminated daily using DI water, and were rinsed with surface water at each station prior to sampling.

3.3.3. Teledyne ISCO 6712 Full Size Portable Sampler

The automated ISCO sampler was used to collect water samples from a specific location at programmed time intervals. The unit consisted of a plastic sampling tube, which was placed into the water at the desired sample location and depth. The tube was connected to the sampling unit, a hard plastic shell containing a digital controller, sampling arm, and 24 – 1 litre (L) plastic bottles. Sampling intervals were programmed into the digital recorder, which instructed the unit to intake water through the tube and the sampling arm to fill one of the 1 L bottles at each desired sampling time. Samples were kept below 4^{o} C by placing ice packs next to the 1 L bottles inside of the unit.

The ISCO sampler was used at QUR-1 in the Quesnel River from August 12, 2014 through October 1, 2014 during the water quality sampling program. The sampling tube was suspended beneath the surface of the water by attaching it to metal bars which were driven into the riverbed. The tube was inspected daily to assess that the water level had not dropped below the tube, and that the tube had not shifted deeper into the water column. The sampling frequency was set to one sample every 8 hours (three samples per day). The samples were retrieved from the ISCO sampler daily, at which time the ice packs were replaced, the samples were transferred into bottles for laboratory analysis, and the 1 L bottles were rinsed with DI water.

3.4. Residential Water Quality Sampling

3.4.1. Residential Intake Sampling

Water samples for the residential water quality sampling program were collected from residential properties on Quesnel Lake. At each property visited, water samples were collected using a Kemmerer or Van Dorn samplers. Depending on the location of water intakes, samples were collected either from the sampling boat at a point approximately 1 m above the water intake point, or from the residents' dock. Details regarding Kemmerer and Van Dorn sampler methodologies are noted in section 3.3.2.

3.5. Sample Procurement and Handling

Water samples for specific parameters were collected using the methodologies, sampling bottles and preservatives listed in Table D below. Samples were placed into ice-chilled coolers and shipped to ALS for analysis under chain-of-custody documentation. Samples were shipped approximately daily (generally on weekdays, with limited weekend shipping as required), on a sufficient frequency to meet parameter hold times as listed in Table D below.

Table D: Parameter-Specific Sampling Methods

Parameter	Methodology	Bottles	Preservation	Hold Time
Dissolved Metals	Use a syringe and 0.45 µm filter disks	1 x 250 mL Plastic	HNO_3	6 months
Total Metals	Typical grab sampling techniques	1 x 250 ml Plastic	HNO_3	6 months
Total Mercury	Typical grab sampling techniques	1 x 40 ml Glass Vial	HCl	28 days
Anions (Cl, SO4, F)	Triple rinse container with sample water before collection	1 x 1L Plastic	N/A	28 days
Total Alkalinity*	Triple rinse container with sample water before collection	1 x 1L Plastic	N/A	14 days
Nitrate/Nitrite*	Triple rinse container with sample water before collection	1 x 1L Plastic	N/A	72 hours
Phosphorus *(dissolved)	Triple rinse container with sample water before collection	1 x 1L Plastic	N/A	72 hours
Phosphorus *(total reactive, ortho-PO4)	Triple rinse container with sample water before collection	1 x 1L Plastic	N/A	72 hours
Total Nitrogen, Ammonia, Total Phosphorous	Typical grab sampling techniques	1 x 250 ml Amber Glass	H_2SO_4	28 days
Dissolved Organic Carbon	Typical grab sampling techniques	1 x 120 ml Amber Glass	H_2SO_4-after filtration	28 days
Speciated Chromium	Typical grab sampling techniques	1 x 125 ml Plastic	NaOH	30 days
Coliforms & E.Coli	Typical grab sampling techniques	1 x 250 ml Plastic	$Na_2S_2O_3$	24-48 hours
EPH	Typical grab sampling techniques	2 x 500 ml Amber Glass	$NaHSO_4$	14 days
Glycols	Typical grab sampling techniques	2 x 40 ml Glass Vial	N/A	7 days

Table D (Cont'd): Parameter-Specific Sampling Methods

Parameter	Methodology	Bottles	Preservation	Hold Time
Non-anionic surfactants	Typical grab sampling techniques	1 x 500 ml Amber Glass	N/A	2 days
Total xanthates	Typical grab sampling techniques	2 x 125 ml Amber Glass	N/A	No standard hold time
Floatation Agents**	Typical grab sampling techniques	2 x 40 ml Glass Vial	$NaHSO_4$	14 days
Chlorophyll-a	Immediately wrap entire sample bottle in tinfoil to prevent light from entering. Not field filtered (filtered in lab)	1 x 250mL Plastic	N/A	48 hours for filtration in lab

* Sampled as part of the Nutrient package.
** Includes acetone, carbon disulfide, heptanes, 2-hexanone, methyl ethyl ketone, methyl isobutyl ketone, 4-methyl-2-pentanol, octane, pentane, 1,2,3-trimethylbenzene

4. DATA MANAGEMENT

For the Mount Polley project, analytical and field data, including station location information, were uploaded to SNC-Lavalin's proprietary environmental management information system, known as esMECI.

esMECI consolidates monitoring and analytical data into a central database for ease of management, analysis and reporting. Data are imported into the system directly from the digital Excel files received from the laboratories, which minimizes the potential for manual keying errors. esMECI also incorporates numerous quality control features to further enhance data confidence.

During the course of the project, information uploaded into esMECI included the following:

- Station location coordinates;
- Sample identification information (e.g., Sample ID, date, depth, duplicate coding);
- Field measurements (i.e., temperature and pH); and
- ALS laboratory analytical results.

Water quality analytical data and field measurements were exported from esMECI into Excel tables on a weekly basis for presentation to MPMC. Tabulated analytical data were compared to selected regulatory comparison guidelines for reference purposes and weekly reporting to third parties. RPDs for blind field duplicate samples were calculated by esMECI during table generation. Results tables were then reviewed manually and compared to the laboratory analytical reports and field notes as a QA/QC measure.

Water column profile field data were entered onto Excel tables manually from field notes, or from YSI EXO files without processing, through esMECI.

5. STAFF QUALIFICATIONS

A summary of qualifications for staff directly involved in water quality data generation and management (SNC-Lavalin, MPMC and other companies) is included in Attachment 5.

6. ACRONYMS AND DEFINITIONS

CALA – Canadian Association for Laboratory Accreditation Inc.

CCME – Canadian Council of Ministers of the Environment

DI – deionized

DO – dissolved oxygen

DQO – data quality objectives

MDL – method detection limit

MPMC – Mount Polley Mining Corporation

ORP – Oxidation-reduction potential

PAH – polycyclic aromatic hydrocarbons

PQL – practical quantitation limit

pH – a measure of the alkalinity or acidity of water, measured on a scale of 1 to 14, with 7 being neutral, less than 7 acidic, and greater than 7 alkaline or basic

QA/QC – quality assurance / quality control

RPD – relative percent difference

TSF – tailings storage facility

Data Integrity and Management Plan and QA/QC Flow Chart

DATA INTEGRITY AND MANAGEMENT FRAMEWORK
MT POLLEY CEIA, AUGUST 15, 2014

The data integrity and management framework (DIMF) will be implemented to track field monitoring data, field documentation, laboratory submissions, the receipt of analytical results, and to verify the quality of those analytical results. All field staff will review and implement the DIMF and relevant Preferred / Standard Operating Procedures (P/SOPs), or document instances where the DIMF cannot be implemented. Field staff will also review and implement relevant provincial guidance documents regarding sampling protocols and P/SOPs, which will be made available on a secure Sharepoint Site. A file sharing protocol is in development and will be integrated into the DIMF at a later time. The following principles make up the DIMF.

1. Work plans will be prepared for all phases of project work and will be executed by trained and qualified personnel.

2. Sample procurement and monitoring will be in accordance with P/SOPs (MPMC, SNC-Lavalin, Minnow, SRK, etc.) and, as applicable, with provincial and/or federal guidance and protocols as referenced in Pollution Abatement Order 107461.

3. Discipline leads will be responsible for ensuring the adequacy of the work plans and that P/SOPs are in place.

4. Field duplicate samples will be collected at an approximate 1 in 10 frequency (10%) for all key laboratory analytical parameters. Field blanks and equipment blanks will be collected at an approximate 5% frequency (1 in 20 samples) or every other day for continuous and similar sampling programs (i.e., water quality monitoring on Quesnel and Polley Lake). De-ionized water blanks and filter blanks are being tested by the batch on an approximate monthly basis. Laboratory soil duplicates (splitting in the lab) will be carried out.

5. A daily record of events will be maintained in bound field books including purpose, time, date, crew members, location, temperature, weather, and any changing ambient conditions that could affect sample integrity (i.e., rain, dust, etc.).

6. Potentially relevant observations regarding biological, geotechnical, or other environmental concerns will be documented and reported to the project coordinator on a daily basis for inclusion in the weekly report to the Project Management team and regulators. Photographs will be taken to support observations and also to provide representative documentation of each field program. All photographs will be saved according to the file sharing protocol, with key photographs labeled.

7. Sampling records will be filled out in full at the field at time of sample collection.

8. GPS waypoints will be recorded at all locations using equipment of suitable accuracy for the purposes of the studies being undertaken. In the event this is not possible, locations will be described in writing (i.e., address) or using a map of appropriate scale and use of identifiable landmarks.

9. Samples will be handled, stored, and transported in accordance with P/SOPs. This includes proper sample preservation including use of ice charged coolers (as required), protecting sample vessels as necessary, shipping within hold times, and use of Chain of Custody documentation. Caution will be taken shipping over weekends or near statutory holidays and should be generally avoided if possible.

10. Chain of Custody (COC) documentation will be filled out in full and submitted to the Data Coordinator at the end of each day along with photographs, field notes, sampling records, and any other relevant field documentation. Files will be stored in appropriate folders as per the file sharing protocol.

11. On a daily basis, the Data Coordinator will update a Sample Tracking Spreadsheet (STS) with sample information shown on submitted COCs including date and time of sampling, sample ID, media type (soil, sediment, water, biological parameters or tissues, etc.). To ensure ease of data management and cross referencing, the STS will be structured to allow data to be sorted by media, sample ID, and laboratory report number.

12. Using the STS, the data coordinator will track sample receipt confirmations and will follow up with the receiving laboratory if sample receipt confirmations (SRCs) are not received. Any deficiencies will be reported to the Project Data Manager (i.e., sample ID discrepancies, missed hold times, elevated temperatures) and corrective action taken to avoid further deficiencies.

13. Analytical report turn-around-time (TAT) will be tracked by the data coordinator and date of report receipt tracked. The laboratory analytical reports will be saved to an appropriate file folder structure on a secure Sharepoint site accessible by appropriate mine and project staff.

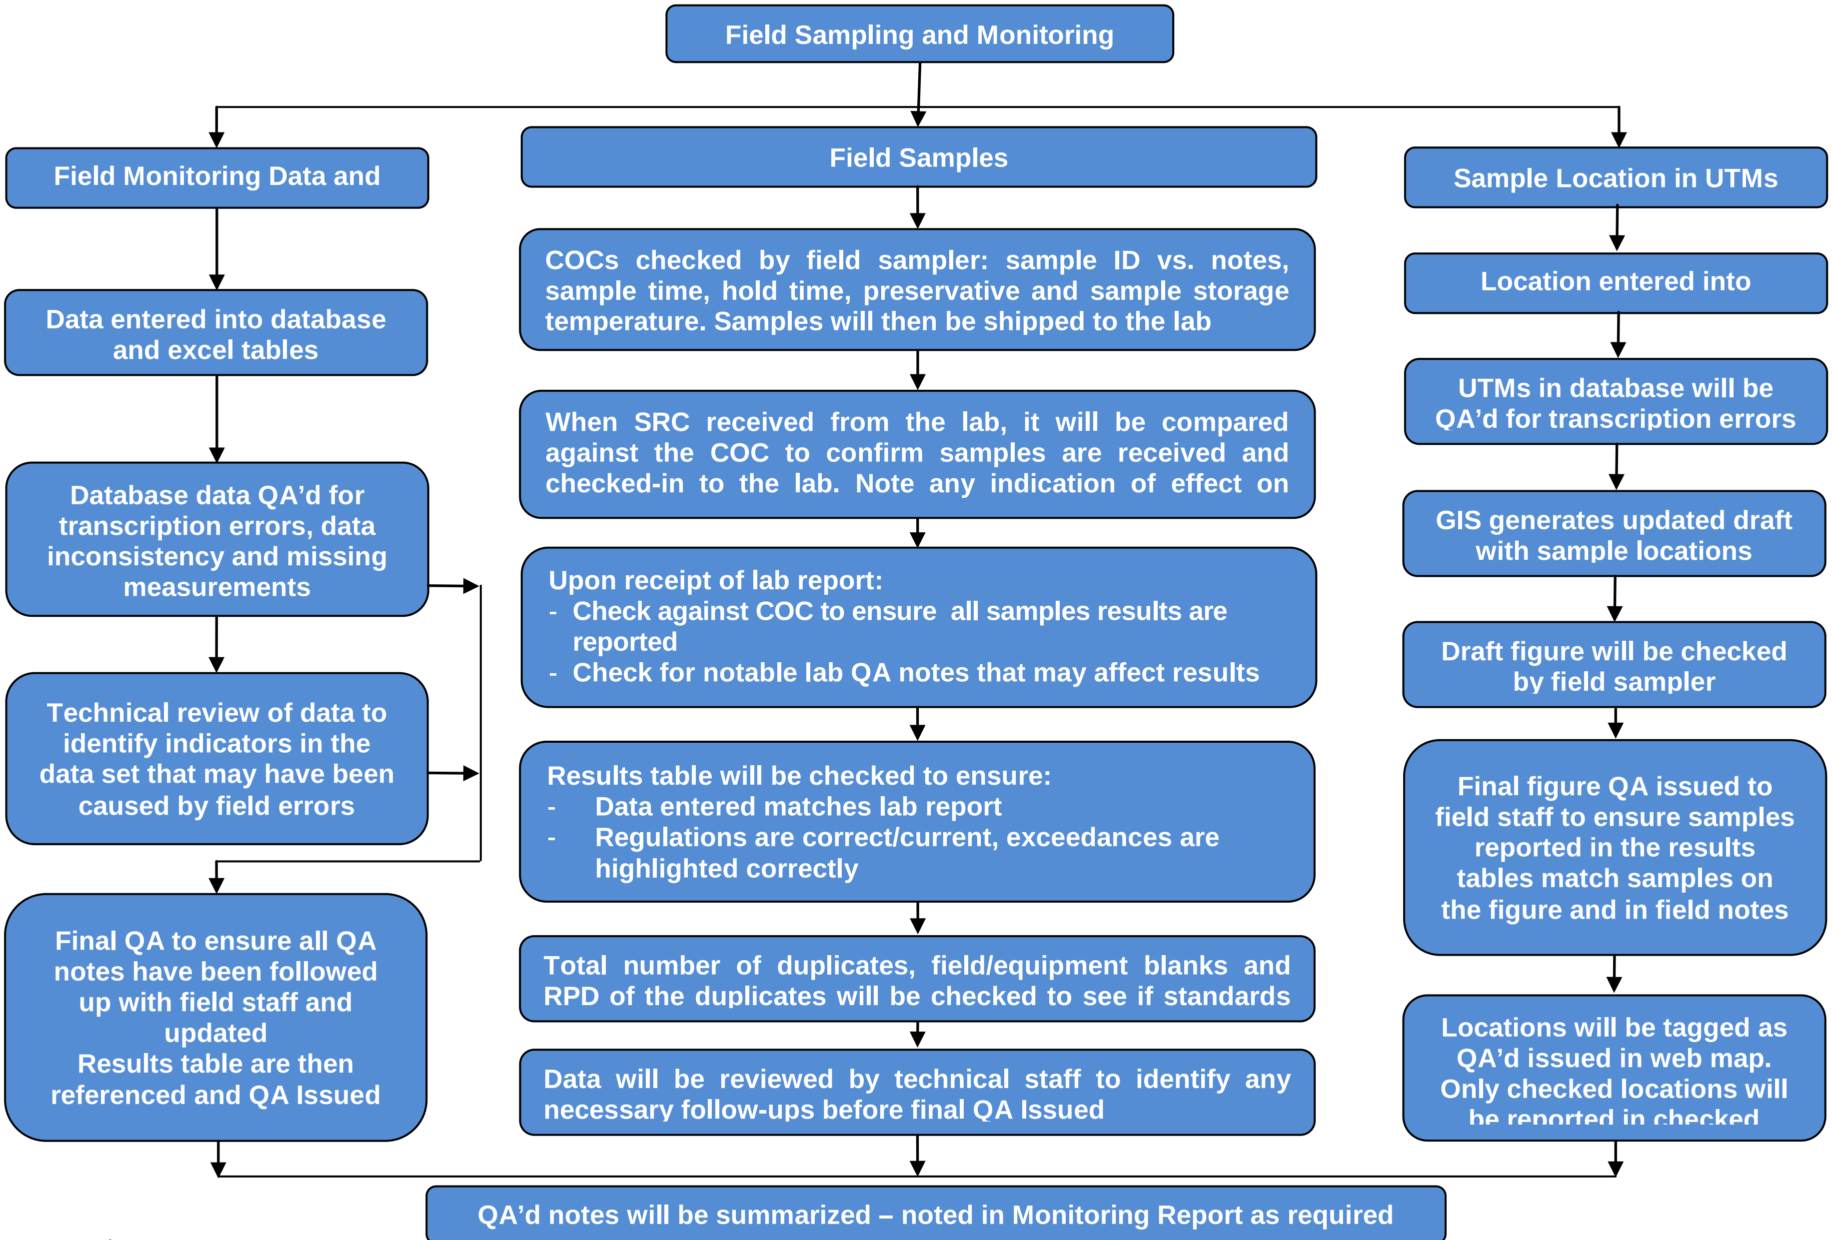
14. All analytical reports will be reviewed upon receipt for completeness, potentially anomalous data, and data quality waivers. This initial QA/QC screen will be tracked on the STS. Appropriate investigations will be initiated as issues are identified (i.e., laboratory re-checks, sample review, etc.).

15. A companion Data QA/QC spreadsheet will be maintained by the Data Coordinator documenting any recorded field or laboratory based QA/QC concerns.

16. The Data Coordinator will be responsible for the transcription of field notes into soil, sediment, or water sample logs as deemed necessary.

17. Relative percent differences (RPDs) for data sample sets will be calculated upon tabulation of the data and investigations initiated as necessary.

A field and desktop audit will be performed periodically to confirm adherence to P/SOPs and the effectiveness of the DIMF. Based on audit results, improvements will be made on a continuous basis.



Legend
COC – Chain of Custody
GIS – Geology Information System
ID – Identification number
QA – quality assured
RPD - Relative Percent Difference
SRC – Sample Receive Confirmation
UTM - Universal Transverse Mercator

Summary of DQO Exceedances

Summary of DQO Exceedances – Mount Polley Water Sampling

Sample Date	Sample ID(s)	Parameter(s) > DQO	Comment
RPD > DQO – Laboratory related QA/QC issues			
24-Sep-14	QUL-120-40m and QUL-120X-40m	T-Cu, T-Pb, T-Ni, T-Zn	Potential contamination during lab sample preparation.
RPD > DQO – Potential Field Sampling Equipment Contamination			
25-Aug-14	QUL-2-0m and QUL-2X-0m	Total P	May be due to high equipment blank noted on August 21, 2014. Data may be positively biased.
28-Aug-14	QUL-66 and QUL-66X	TSS	High equipment blank on KEM1B. Data may be positively biased.
28-Aug-14	QUL-66 and QUL-66X	Total P	High equipment blank on KEM1B. Data may be positively biased.
28-Aug-14	QUL-66 and QUL-66X	D-Al, T-Co, T-Fe, T-V	High equipment blank on KEM1B. Data may be positively biased.
26-Oct-14	QUL-120-40m and QUL-120X-40m	T-Pb	BLC blanks high on a few metals and T-P. Data may be positively biased.
12-Nov-14	QUL-79-50 and QUL-79x-50m	D-Mn, T-Pb	T-Pb exceeded MDL in KEM1B blank Nov 10 and 18th. No exceedences. Data may be positively biased.
RPD > DQO – No Regulatory Exceedances			
07-Aug-14	QUL-11-5m and QUL-11-5mx	Turbidity	No regulatory exceedences.
12-Aug-14	QUL-21 and QUL-21X	D-Mn, D-U	No comparison guidelines.
13-Aug-14	QUL-9 and QUL-9X	T-Al	No regulatory exceedances.
18-Aug-14	POL-3 and POL-3X	D-Mn	No comparison guidelines.
18-Sep-14	QUL-23 and QUL-23X	D-Mn	No comparison guidelines.
23-Sep-14	QUL-21-0m and QUL-21X-0m	T-Al,T-Mn	No regulatory exceedances.
23-Sep-14	QUL-23 and QUL-23X	D-Mn	No comparison guidelines.
25-Sep-14	QUL-66A-0m and QUL-66AX-0m	Chlorophyll A	No regulatory exceedances
28-Sep-14	QUL-87-0m and QUL-87X-0m	Chlorophyll A	No regulatory exceedances
10-Oct-14	HAD-1 and HAD-1X	Turbidity	No regulatory exceedances
25-Aug-14	QUL23 and QUL23X	Turbidity	Poor repeatability between the field duplicate samples.
11-Sep-14	QUL-66-50m and QUL-66X-50	Turbidity, T-Fe	Poor repeatability between the field duplicate samples.
01-Oct-14	QUL-66-40m and QUL-66x-40m	D-Al	Poor repeatability between the field duplicate samples.
14-Oct-14	QUL-2A-40m and QUL-2X-40m	Turbidity, sulphate, D-Mn, D-K, D-Na, D-Ba, D-Cu, D-Mo, D-U D-Al, T-Cu, T-Pb, T-Mn, T-Al, T-Ba, T-Fe, T-Mo, T-K, T-Si, T-Na, T-U	Poor repeatability between the field duplicate samples.

Summary of DQO Exceedances – Mount Polley Water Sampling (Cont'd)

Sample Date	Sample ID(s)	Parameter(s) > DQO	Comment
21-Oct-14	QUL-2A-40m and QUL-2AX-40m	T-Pb	Poor repeatability between the field duplicate samples.
11-Nov-14	QUL-66-55m and QUL-66X-55	T-P	Poor repeatability between the field duplicate samples.
12-Nov-14	QUL-79-50 and QUL-79x-50m	Turbidity	Poor repeatability between the field duplicate samples.
10-Oct-14	HAD-1 and HAD-1X	Turbidity	Poor repeatability between the field duplicate samples.
06-Sep-14	HAC-1 and HAC-1X	D-Al, D-Mn, D-Ba, D-Cu	Poor repeatability between the field duplicate samples.
19-Sep-14	HAC-1 and HAC-1X	D-Al,	Poor repeatability between the field duplicate samples.
1-Oct-14	HAC-05	T-P	Poor repeatability between the field duplicate samples.
26-Nov-14	HAC-01a	D-Al	Poor repeatability between the field duplicate samples.
12-Aug-14	POL-4 and POL-4X	Turbidity	Poor repeatability between the field duplicate samples.
14-Oct-14	POL-5-0m and POL-5X-0m	Nitrate nitrogen	Poor repeatability between the field duplicate samples
16-Sep-14	P1-0m and P1X-0m	Turbidity	Poor repeatability between the field duplicate samples
12-Nov-14	P1-0m and P1X-0m	Turbidity	Poor repeatability between the field duplicate samples
Equipment Blanks > DQO			
19-Aug-14	QUL equipment blank	T-Ba, T-Pb,T-Mn	Data may be positively biased.
21-Aug-14	QUL equipment blank	T-P, D-Na, T-Na	Data may be positively biased.
28-Aug-14	KEM1B blank	T-Al, T-As, T-Ba, T-Ca, T-Co, T-Cu, T-Fe, T-Pb, T-Mn, T-Si	Data may be positively biased.
10-Nov-14	KEM1B blank	T-Pb	Data may be positively biased.
18-Nov-14	KEM1B blank	T-Pb	Data may be positively biased.
26-Oct-14	BLC	T-P	Data may be positively biased.
27-Aug-14	ISCO	T-Al, T-Ba, T-Ca, T-Cu, T-Mn, T-Si	Data may be positively biased.
9-Sep-14	ISCO	T-Al, T-Ba, T-Ca, T-Mn, T-Si	Data may be positive biased.

T – total
D – dissolved
Al – aluminum
Ba – barium
Cd – cadmium
Co – cobalt
Cr – chromium
Cu – copper
Fe – iron
K – potassium
Mo – molybdenum
Na – sodium
Ni – nickel
P – phosphorous
Pb – lead
Si – silicon
Ti – titanium
U – uranium
V – vanadium
Zn – zinc
Mn – manganese
TSS – total suspended solids

Summary of Staff Qualifications

Mount Polley Water Quality Program
Summary of Staff Qualifications

Name	Project Role	Description of Experience and Qualifications	Years of Experience	Professional Designation(s)
Field Monitoring and Sampling				
MPMC				
Colleen Hughes	Environmental Coordinator	Water and Soil Quality, Re-Vegetation, Project Coordination	12	EP
Jack Love	Environmental Manager	Project Management, Impact Assessment Biology	19	R.P.Bio
Katie McMahen	Project Coordination, Data Mgmt, Logistics	Reclamation, Hydrology, Water Management, Project Coordination	3.5	P. Ag
Gabriel Holmes	Project Coordination, Water Quality support, Field Sampler	Silviculture, field sampling	2.5	Certified Silvicultural Surveyor, Certified Danger and Wildlife Tree Assessor
Maclean Donohoe	Project Coordination, Water Quality support, Field Sampler	B.Sc in Geology, field sampling/assistance	<1	
Shauna Litke	Water Quality Support, Field Sampler, Data Mgmt	Metallurgy	<1	EIT
Sky Freeman	Water Quality Support, Field Sampler	Currently completing a B.Sc in Biology, field sampling/assistance	<1	
Ira Pierce	Assist with field data collection	Project-specific training for field data collection	<1	
Fernando John	Assist with field data collection	Project-specific training for field data collection	<1	
Gilbert Sellars	Assist with field data collection	Project-specific training for field data collection	<1	
Frank Abbott	Assist with field data collection	Project-specific training for field data collection	<1	
Everett Dan	Assist with field data collection	Project-specific training for field data collection	<1	
Cariboo Environmental Quality				
Norm Zirnhelt	Water Quality Support, Limnology Support, Fisheries Biology Support, EIA Support	Water Quality, Environmental Monitoring, Impact Assessment, Fisheries Technical/Field Assistance	>20	R.P.Bio
Candice Collier	Assist with field data collection	Water Quality, Benthic Monitoring, and Riparian Assessments	5	B.Sc.
Minnow				
Pierre Stecko	Lead - Sediment Impact Assessment, Water Quality Support, Field Sampler	Aquatic toxicology and sediment geochemistry	19	M. Sc., RPBio, EP
Mike White	Sediment Support, Water Quality Support, Field Sampler	Benthic Ecology and Biostatistics, Field studies	6	Ph. D.
Katharina Batchelar	Sediment Support, Water Quality Support, Field Sampler	Sediment, Benthic Biology	1	M. Sc.
EBA Tetratech				
Justin Rogers	Data Collection & Interpretation	M.Sc., Geological Oceanography, three dimensional numerical modeling, Data Collection & Interpretation	8	American Geophysical Union, Association for the Sciences of Limnology and Oceanography, Candanian Meteorological and Oceanographic
SNC-Lavalin				
Laura McOrmond	QA/QC Officer, Onsite Coordination, Water Quality/Project Support, Field Sampler	Contaminated sites assessment and monitoring	2.5	
Doug Curley	Water Quality/Project Support, Field Sampler	Contaminated sites assessment and monitoring	<1	
Mike Schutten	Water Quality/Project Support, Field Sampler	Contaminated sites assessment and monitoring	<1	
Troy Lange	Water Quality/Project Support, Field Sampler	Contaminated sites assessment and monitoring	4	
Jeff Lomon	Water Quality Support, Field Sampler	Contaminated sites assessment and monitoring	3	
Tyler Anderson	Water Quality Support, Field Sampler	Contaminated sites assessment and monitoring	7	EP
Trevor McConkey	Lead - Soil Impact Assessment, PM Support and Coordination, Field Sampler and Auditor	Soil and Water Quality, Reclamation and Re-Vegetation	15	M.Sc., P.Ag.
Jenn Piquard	Health & Safety Support, Water Quality Support, Field sampler	H&S, QA/QC, Onsite Coordination	5	A.Sc.T.
August Whelan	Water Quality Support (field instrument readings)	Geotechnical Engineer-In-Training	1.5	
Sarah Jossul	Water Quality Support (field instrument readings)	Junior Environmental Professional	4.5	B.I.T.
Eve Edmonstone	Water Quality Support (field instrument readings)	Geoenvironmental Engineer-In-Training	3	EIT
Mia Sakelariou	Data Management & Tabulation	Data management, database administration, tabulation, regulatory standards	12	
Natalie Neufeld	Data Management & Tabulation	Data management, database administration, tabulation, regulatory standards	9

MOUNT POLLEY POST-EVENT WATER QUALITY MONITORING PROGRAM DATA QUALITY REPORT

TO: Golder Associates Ltd.

FROM: Mount Polley Mining Corporation

DATE: March 26, 2015

TABLE OF CONTENTS

1 INTRODUCTION

On December 20, 2014, program oversight and data management for the water quality monitoring program following the Mount Polley Tailings Storage Facility (TSF) breach transitioned to Mount Polley Mining Corporation (MPMC) from SNC-Lavalin Inc. (SNC-Lavalin). The following details any changes after the transition in the field sampling methods and data quality assurance / quality control (QA/QC) measures for the water quality monitoring and sampling program.

2 QUALITY ASSURANCE / QUALITY CONTROL

MPMC implemented a QA/QC program similar to the one developed by SNC-Lavalin during the water quality monitoring and sampling program. Refer to the Memorandum titled "Summary of Data Quality Assurance / Quality Control and Field Methods for the Mount Polley Water Quality Monitoring and Sampling Program" by SNC-Lavalin (herein referred to as "SNC-Lavalin Memorandum") for details. Report structure and key statements were transcribed from the SNC-Lavalin Memorandum for consistency. MPMC staff directed the field data collection program starting November 20, 2014 and managed the QAQC program starting December 20, 2014. The QA/QC program included:

- Quality assurance (QA): management and technical practices designed to confirm that data were consistent with the objectives of the water quality program and that data were scientifically tenable
- Quality control (QC): specific data quality objectives (DQOs), statistical assessment of data quality, and corrective measures taken whenever the DQOs were not met

The following sections detail the changes implemented to the QA/QC program for the water quality monitoring and sampling program after December 20, 2014.

2.1 Field Data Collection and Document Control

For full equipment methodologies and calibration details, refer to sections 3.1 through 3.3 in the SNC-Lavalin Memorandum.

After November 19, 2014, all field data and samples were collected by MPMC staff. Field data related to the water quality program for the Mount Polley TSF breach were collected and tracked using field notebooks specific to each area of interest. Water sample collection, field data collection not electronically logged, equipment calibration done in the field (e.g. dissolved oxygen (DO) calibration), photographic recordkeeping, and daily observations tracking were recorded in these notebooks. Field notebooks were reviewed daily to confirm that records were filled out in full, accurate, and consistent with other information submitted, and were scanned and saved electronically according to date and area of interest. Individual samples were tracked using a spreadsheet which recorded the locations of samples, along with the date, duplicate and blank sample information, sample shipping information, laboratory correspondence, analytical results and data integrity issues.

2.2 Analytical Laboratory

Samples continued to be shipped to ALS Environmental (ALS) in Burnaby, BC for analaysis. ALS is a Canadian Association for Laboratory Accreditation Inc. (CALA) accredited laboratory. Water samples submitted were tracked for adherence to laboratory sampling and analysis protocols, including hold times, sample containers, preservatives, detection limits, and approved methodology. Sample integrity issues when these protocols were not adhered to were recorded in the sample tracking sheet. Refer to Section 2.2 in the SNC-Lavalin Memorandum for details on the QA/QC program of ALS.

2.3 QA/QC Samples

Quality control samples collected during the water quality sampling program included blind field duplicate samples, equipment blanks, filter blanks, field blanks, deionized (DI) water blanks and trip blanks. For a description of each QC sample, refer to the SNC-Lavalin Memorandum.

The target frequencies of duplicate samples and blanks that were adopted for the QA/QC program are summarized in Table 2.1 below.

Table 2.1 QA/QC Duplicate and Blank Target Frequencies

QA Sample Type	Target Frequency	Applicable Parameters
Blind Field Duplicates	10 %	All parameters
Equipment Blanks	Bi-weekly when equipment in use	All parameters
Filter Blanks	Quarterly	Dissolved Metals
Field Blanks	Monthly	All organic parameters
DI Water Blanks	Quarterly	Total Metals
Trip Blanks	Monthly	Volatiles only

A summary of the duplicate and blank frequencies achieved is included in Section 2.4.1.

2.3.1 Data Quality Objectives

To assess blind field duplicate results relative to DQOs, MPMC followed the calculations set out by SNC-Lavalin described in Section 2.3.1 of the SNC-Lavalin Memorandum for all parameters except low-level results. The practical quantitation limit (PQL) which was defined as five times the laboratory method detection limit (MDL) was calculated. For analytes in blind field duplicate sets where concentrations were above the PQL, the relative percent difference (RPD) was calculated as described in Section 2.3.1 in the SNC-Lavalin Memorandum. For low-level results (when results were below the PQL), MPMC followed guidance provided by ALS; if the difference between the two samples was greater than twice the MDL, the results were flagged.

2.4 Summary of QA/QC Results

QA/QC procedures were followed throughout the program to determine if the analytical results were accurate. Chain-of-custody (COC) records were completed electronically to minimize transcription errors at ALS upon receiving samples. All Sample Receipt Confirmation (SRC) reports were reviewed by MPMC upon receipt from ALS for sample integrity issues, to verify samples IDs, dates and analyses were correct and hold times were met. Any sample integrity issues were documented in the sample tracking spreadsheet. When analytical results were received, the data were reviewed for laboratory data qualifiers and any data anomalies were investigated.

2.4.1 Duplicates and Blank Samples

The total duplicate and blank samples that were collected during the water sampling program from December 20, 2014 to February 28, 2015 are indicated in Table 2.2.

Table 2.2 Summary of Duplicate and Blank Samples From December 20, 2014 to February 28, 2015

QA Sample Type	Quesnel Lake	Quesnel River	Polley Lake	Hazeltine Creek	Program Total
Regular Samples	2	14	1	27	44
Field Duplicates	0	2 (14.3%)	0	2 (7.4%)	4 (9.1%)
Equipment Blanks	0	N/A	0	N/A	0
Filter Blanks	0	0	0	N/A	0
Field Blanks	0	1	0	1	2 (4.5%)*
DI Water Blanks	0	0	0	0	0
Trip Blanks	0	1	0	1	2 (4.5%)*

* Indicates target frequency of monthly was met

2.4.2 Relative Percent Differences

Blind duplicate sample sets for which RPD values exceeded the DQO are summarized in Table 2.3, and are separated by type of RPD issue.

Table 2.3 Summary of RPD Exceedances

Sample Date	Sample IDs	Parameter RPD > DQO	Comment
RPD > DQO, Regulatory Exceedances Identified			
27-Jan-15	HAC-05 and HAC-05x	Dissolved Al	Poor repeatability between the field duplicate samples
RPD > DQO, No Regulatory Exceedances			
12-Aug-14	HAC-08 and HAC-08x	Total P	No exceedances

Once an RPD exceedance was identified, the associated results were subsequently compared to relevant guidelines, and the laboratory was contacted if one or both concentrations were greater than guideline(s). For RPD exceedances due to laboratory related issues, corrective action was initiated by reanalyzing the batch of affected samples.

2.4.3 Blank Sample Issues

Only one blank, the Hazeltine trip blank taken February 2, 2015, was flagged with detectable total manganese (0.000006 mg/L above the MDL).

2.4.4 Laboratory QA Results

There were no dissolved metals concentrations greater than total metals concentrations in any samples.

3 FIELD MONITORING AND SAMPLING METHODOLOGY

The sections below outline the changes of the methodologies SNC-Lavalin implemented for the collection of field data and samples during the water quality field program.

3.1 Monitoring and Sampling Locations

Coordinates for each new station were recorded in field notebooks and uploaded into an EHS Data MP-5 Database and associated with the relevant samples at each station. Coordinates for new stations were programmed into other onsite field GPS units for future sampling visits. Coordinates were used to generate drawings showing station locations to date, which were subsequently verified by field staff.

Sample ID nomenclature was kept consistent with established IDs and naming systems, as described in Section 3.1 in the SNC-Lavalin Memorandum.

3.2 Water Quality Monitoring and Column Profiling

MPMC continued to use the procedures outlined in Section 3.2 of the SNC-Lavalin Memorandum for water quality monitoring and column profiling. The sonde deployed at QUR-1 continued to monitor the Quesnel Lake outflow on Quesnel River, logging every 15 minutes. Another sonde was deployed on January 19, 2015 at the outlet of the lower sedimentation pond (sample ID: HAC-01b) to monitor the outflow of Hazeltine Creek into Edney Creek and Quesnel Lake, which also logs every 15 minutes.

Two Manta Eureka 2 sondes, which monitor temperature, specific conductivity and turbidity every 30 minutes, were also deployed at two hydrology stations. One was near the Gavin Lake Bridge (sample ID: HAC-05), which was installed from November 5-26, 2014 and the other just upstream of the Ditch Road Bridge (near HAC-08), which was installed from November 6-26, 2014.

3.3 Water Sampling

Water sampling by MPMC was completed using the methods outlined in Section 3.3 of the SNC-Lavalin Memorandum for water sampling.

3.4 Residential Water Quality Sampling

No residential intake samples were requested or taken after December 20, 2014.

3.5 Sample Procurement and Handling

All sample procurement and handling was conducted as outlined in Section 3.5 of the SNC-Lavalin Memorandum for water sampling. Shipping frequency decreased to 2-3 times a week and depended on the number of samples. Samples were shipped additional days as needed to avoid hold time exceedances. For a summary of hold time exceedance periods, see Table D in Section 3.5 of SNC-Lavalin Memorandum.

4 DATA MANAGEMENT

Analytical and field data, including station location information, were uploaded to MPMC's established EHS Data MP-5 Water Quality Database (MP-5). MP-5 consolidates monitoring and analytical data for ease of management, analysis, relevant guideline exceedances (e.g. BC Water Quality Guidelines) and reporting.

4.1 Station Locations and Identification

Station location coordinates were saved in MP-5 and were mapped ad hoc to ensure correct coordinates. Sample IDs, along with sample depth and sample type, such as duplicate classification, were saved and sorted by location of interest in MP-5. Results from all blanks were also uploaded.

4.2 Analytical Data

Analytical data are imported into MP-5 directly from the comma-separated value (.csv) files generated by ALS, which minimizes the potential for manual keying errors. Physical minimums and maximums are also stored in MP-5 and the importer compares these to imported data. Any data point out of its physical range is flagged and is investigated.

4.3 Field Measurements

From December 2014 to January 2015, MPMC cross-referenced all raw field documents with analytical data in the MP-5 database from August 4, 2014 to date to ensure all data were correct and uploaded in the database, including any relevant comments by field staff. Any discrepancies found were investigated and corrected in the MP-5 database.

Field measurements uploaded were the following:

- In-situ temperature
- In-situ specific conductivity
- In-situ pH
- In-situ DO
- In-situ turbidity
- Secchi disc readings, including weather comments or lake observations

4.4 Lake Profiles

Lake profile data was exported from the EXO sondes to EXO handhelds and uploaded to and saved on the MPMC network. All raw data files were saved, and copies were used to compile or analyse data.

5 STAFF QUALIFICATIONS

A summary of qualifications for MPMC staff directly involved in water quality data generation and management is included in Table 5.1.

.

Table 5.1 MPMC Staff Qualifications

Name	Project Role	Description of Experience and Qualifications	Years of Experience	Professional Designation(s)
Colleen Hughes	Environmental Coordinator	Water and Soil Quality, Re-Vegetation, Project Coordination	12	EP
Katie McMahen	Project Coordination, Data Mgmt, Logistics	Reclamation, Hydrology, Water Management, Project Coordination	3.5	P. Ag
Gabriel Holmes	Project Coordination, Water Quality support, Field Sampler	Silviculture, field sampling	2.5 (>10 years silviculture experience)	Certified Silvicultural Surveyor, Certified Danger and Wildlife Tree Assessor (>10 years silvicuture experience)
Maclean Donohoe	Project Coordination, Water Quality support, Field Sampler	B.Sc in Geology, field sampling/assistance	<1	
Shauna Litke	Water Quality Support, Field Sampler, Data Mgmt	Metallurgy	<1	EIT (2 years metallurgical engineering experience)
Ira Pierce	Assist with field data collection		<1	
Fernando John	Assist with field data collection		<1	
Gilbert Sellars	Assist with field data collection		<1	
Frank Abbott	Assist with field data collection		<1	
Alethea Andy	Assist with field data collection		<1	

6 ACRONYMS

CALA – Canadian Association for Laboratory Accreditation Inc.

COC – Chain-of-custody

DI – deionized

DO – dissolved oxygen

DQO – data quality objectives

MDL – method detection limit

MPMC – Mount Polley Mining Corporation

PQL – practical quantitation limit

QA/QC – quality assurance / quality control

RPD – relative percent difference

TSF – Tailings Storage Facility

Notes:

A = approved guideline, W = working guideline, Min = Minimum concentration requirement based on life stage, IR = irrigation guideline, WW = wildlife water supply guidelines, DW = drinking water guidelines

a) BC Water Quality (BCWQ) guidelines for the protection of freshwater aquatic life except where noted (e.g., total aluminum, molybdenum, pH)

b) up to 4 - highly sensitive to acid inputs; 4 to 8 - moderately sensitive; over 8 - low sensitivity. Refer to alkalinity, the more restrictive of calcium or alkalinity applies.

c) based on threshold for Daphnia magna immobilization of 373-432 as KCl

d) hardness dependent F guideline: BC Max WQG (mg/L) = 0.4 at hardness of 10 mg/L, otherwise = (-51.73 + (92.57 *log(hardness)))*0.01

e) hardness dependent sulphate guideline: BC 30-d WQG (mg/L) = 128 at hardness <30 mg/L, at hardness 31-75 mg/L = 218, at hardness 76-180 mg/L = 309, at hardness 181-250 mg/L = 429, at hardness >250 mg/L determine base on site water

f) pH and temperature dependent ammonia guideline: values selected from Tables 3 and 4 in BC WQG based on maximum temperature of 20°C and pH 8.2

g) chloride dependent nitrite guideline: BC Max WQG (mg/L) = 0.06 at Cl <2 mg/L, at Cl 2-4 mg/L = 0.12, at Cl 4-6 mg/L = 0.18, at Cl 6-8 mg/L = 0.24, at Cl 8-10 = 0.30, at Cl >10 = 0.6
BC 30-d WQG (mg/L) = 0.02 mg/L at Cl <2 mg/L, at Cl 2-4 mg/l = 0.04, at Cl 4-6 mg/L = 0.06, at Cl 6-8 mg/L = 0.08, at Cl 8-10 mg/L = 0.1, at Cl >10 = 0.2

h) pH dependent dissolved Al guideline: BC Max WQG (mg/L) = 0.1 at pH≥6.5, at pH <6.5 = EXP(1.209-2.426*(pH)+0.286*(pH2)); BC 30-d WQG (mg/L) = 0.05 at pH ≥6.5, at pH <6.5 = EXP(1.6-3.327*(median pH)+0.402*(median pH2); minimum baseline surface water pH = 5.57

i) hardness dependent dissolved Cd guideline: max BC WQG (mg/L) = (exp(1.03*ln(hardness)-5.274))/1000 BC 30-d WQG (mg/L) = (exp(0.736*ln(hardness)-4.943))/1000

j) guideline is for Cr(VI)

k) hardness dependent Cu guideline: BC Max WQG (mg/L) = (0.094(hardness)+2)/1000; BC 30-d WQG (mg/L) = 0.002 at hardness≤50 mg/L , at hardness >50 mg/L = 0.04*hardness/1000

l) hardness dependent Pb guideline: BC Max WQG (mg/L) = 0.003 at hardness≤8 mg/L, at hardness >8 mg/L = (EXP((1.273*ln(hardness))-1.46))/1000; BC 30-d WQG (mg/L) = (3.31+EXP(1.273(ln(hardness))-4.704))/1000 at hardness >8 mg/L, no guideline at hardness≤8 mg/L

m) hardness dependent Mn guideline: BC Max WQG (mg/L) = 0.01102*(hardness)+0.54; BC 30-d WQG (mg/L) = 0.0044*hardness+0.605

n) BC 30-d WQG (mg/L) = 0.00002 when methylmercury (MeHg) is 0.5% of total Hg, = 0.00001 at 1% MeHg, = 0.00000125 at 8% MeHg; applied middle guideline

o) hardness dependent Ni guideline: BC 30-d WQG = 0.025 at hardness <60 mg/L, at hardness 60-120 mg/L =0.065, at hardness 120-180 mg/L = 0.11, at hardness >180 mg/L = 0.15

p) hardness dependent Ag guideline: BC Max WQG (mg/L) = 0.0001 at hardness≤100 mg/L, at hardness >100 mg/L = 0.003; BC 30-d WQG (mg/L) = 0.00005 at hardness ≤100 mg/L, at hardness > 100 mg/L = 0.0015

q) hardness dependent Zn guideline: BC Max WQG (mg/L) = (33+0.75(hardness-90))/1000; BC 30-d WQG (mg/L) = (7.5+0.75(hardness-90))/1000

r) up to 10 - highly sensitive to acid inputs; 10 to 20 - moderately sensitive; over 20 - low sensitivity. Refer to calcium regarding sensitivity to acid inputs, the more restrictive of calcium or alkalinity is applicable.

nm - not measured
< reported value is <MDL
* = MDLs that are >WQG

123	Indicates concentration exceeding the BC Max WQ Guideline
123	Indicates concentration exceeding the BC 30-d WQ Guideline
123	Indicates concentration exceeding >20% baseline (95th percentile) for parameters without BC WQGs, or parameters without BC WQGs and baseline

Notes:

Exceedance factors were calculated by dividing the 95th percentile to the cooresponding BC WQG under the most conservative scenario

A = approved guideline, W = working guideline, Min = Minimum concentration requirement based on life stage, IR = irrigation guideline, WW = wildlife water supply guidelines, DW = drinking water guidelines

a) BC Water Quality (BCWQ) guidelines for the protection of freshwater aquatic life except where noted (e.g., molybdenum, pH)

b) chloride dependent nitrite guideline: BC Max WQG (mg/L) = 0.06 at Cl <2 mg/L, at Cl 2-4 mg/L = 0.12, at Cl 4-6 mg/L = 0.18, at Cl 6-8 mg/L = 0.24, at Cl 8-10 = 0.30, at Cl >10 = 0.6

BC 30-d WQG (mg/L) = 0.02 mg/L at Cl <2 mg/L, at Cl 2-4 mg/l = 0.04, at Cl 4-6 mg/L = 0.06, at Cl 6-8 mg/L = 0.08, at Cl 8-10 mg/L = 0.1, at Cl >10 = 0.2

c) pH dependent dissolved Al guideline: BC Max WQG (mg/L) = 0.1 at pH ≥6.5, at pH <6.5 = EXP(1.209-2.426*(pH)+0.286*(pH2)); BC 30-d WQG (mg/L) = 0.05 at pH ≥6.5, at pH <6.5 = EXP(1.6-3.327*(median pH)+0.402*(median pH2); minimum baseline surface water pH = 5.57

d) guideline is for Cr(VI)

e) hardness dependent Cu guideline: BC Max WQG (mg/L) = (0.094(hardness)+2)/1000; BC 30-d WQG (mg/L) = 0.002 at hardness ≤50 mg/L , at hardness >50 mg/L = 0.04*hardness/1000

f) BC 30-d WQG (mg/L) = 0.00002 when methylmercury (MeHg) is 0.5% of total Hg, = 0.00001 at 1% MeHg, = 0.00000125 at 8% MeHg; applied middle guideline

g) value exceeds the guideline under the most conservative scenario but not the least conservative scenario

< reported value is <MDL

* = MDLs that are >WQG

123	Indicates concentration exceeding the BC Max WQ Guideline
123	Indicates concentration exceeding the BC 30-d WQ Guideline
123	Indicates concentration exceeding >20% baseline (95th percentile) without BC WQG

Table C-3: Post-event Water Quality in Hazeltine Creek, August 2014 to February 2015

Notes:

Exceedance factors were calculated by dividing the 95th percentile to the cooresponding BC WQG under the most conservative scenario

A = approved guideline, W = working guideline, Min = Minimum concentration requirement based on life stage, IR = irrigation guideline, WW = wildlife water supply guidelines, DW = drinking water guidelines

a) BC Water Quality (BCWQ) guidelines for the protection of freshwater aquatic life except where noted (e.g., total aluminum, molybdenum, pH)

b) value exceeds the guideline at the most conservative scenario but not the least conservative scenario

c) hardness dependent sulphate guideline: BC 30-d WQG (mg/L) = 128 at hardness <30 mg/L, at hardness 31-75 mg/L = 218, at hardness 76-180 mg/L = 309, at hardness 181-250 mg/L = 429, at hardness >250 mg/L determine base on site water

d) pH dependent dissolved Al guideline: BC Max WQG (mg/L) = 0.1 at pH ≥6.5, at pH <6.5 = EXP(1.209-2.426*(pH)+0.286*(pH2)); BC 30-d WQG (mg/L) = 0.05 at pH ≥6.5, at pH <6.5 = EXP(1.6-3.327*(median pH)+0.402*(median pH2); minimum baseline surface water pH = 5.57

e) guideline is for Cr(VI)

f) hardness dependent Cu guideline: BC Max WQG (mg/L) = (0.094(hardness)+2)/1000; BC 30-d WQG (mg/L) = 0.002 at hardness ≤50 mg/L , at hardness >50 mg/L = 0.04*hardness/1000

g) hardness dependent Pb guideline: BC Max WQG (mg/L) = 0.003 at hardness ≤8 mg/L, at hardness >8 mg/L = (EXP((1.273*ln(hardness))-1.46))/1000; BC 30-d WQG (mg/L) = (3.31+EXP(1.273(ln(hardness))-4.704))/1000 at hardness >8 mg/L, no guideline at hardness ≤8 mg/L

h) hardness dependent Mn guideline: BC Max WQG (mg/L) = 0.01102*(hardness)+0.54; BC 30-d WQG (mg/L) = 0.0044*hardness+0.605

i) BC 30-d WQG (mg/L) = 0.00002 when methylmercury (MeHg) is 0.5% of total Hg, = 0.00001 at 1% MeHg, = 0.00000125 at 8% MeHg; applied middle guideline

j) hardness dependent Ni guideline: BC 30-d WQG = 0.025 at hardness <60 mg/L, at hardness 60-120 mg/L =0.065, at hardness 120-180 mg/L = 0.11, at hardness >180 mg/L = 0.15

k) hardness dependent Ag guideline: BC Max WQG (mg/L) = 0.0001 at hardness ≤100 mg/L, at hardness >100 mg/L = 0.003; BC 30-d WQG (mg/L) = 0.00005 at hardness ≤100 mg/L, at hardness > 100 mg/L = 0.0015

l) hardness dependent Zn guideline: BC Max WQG (mg/L) = (33+0.75(hardness-90))/1000; BC 30-d WQG (mg/L) = (7.5+0.75(hardness-90))/1000

Notes:

A = approved guideline, W = working guideline, Min = Minimum concentration requirement based on life stage, IR = irrigation guideline, WW = wildlife water supply guidelines, DW = drinking water guidelines

a) BC Water Quality (BCWQ) guidelines for the protection of freshwater aquatic life except where noted (e.g., total aluminum, molybdenum, pH)

b) up to 4 - highly sensitive to acid inputs; 4 to 8 - moderately sensitive; over 8 - low sensitivity. Refer to alkalinity, the more restrictive of calcium or alkalinity applies.

c) based on threshold for Daphnia magna immobilization of 373-432 as KCl

d) hardness dependent F guideline: BC Max WQG (mg/L) = 0.4 at hardness of 10 mg/L, otherwise = (-51.73 + (92.57 *log(hardness)))*0.01

e) hardness dependent sulphate guideline: BC 30-d WQG (mg/L) = 128 at hardness <30 mg/L, at hardness 31-75 mg/L = 218, at hardness 76-180 mg/L = 309, at hardness 181-250 mg/L = 429, at hardness >250 mg/L determine base on site water

f) pH and temperature dependent ammonia guideline: values selected from Tables 3 and 4 in BC WQG based on maximum temperature of 20°C and pH 8.2

g) chloride dependent nitrite guideline: BC Max WQG (mg/L) = 0.06 at Cl <2 mg/L, at Cl 2-4 mg/L = 0.12, at Cl 4-6 mg/L = 0.18, at Cl 6-8 mg/L = 0.24, at Cl 8-10 = 0.30, at Cl >10 = 0.6
BC 30-d WQG (mg/L) = 0.02 mg/L at Cl <2 mg/L, at Cl 2-4 mg/l = 0.04, at Cl 4-6 mg/L = 0.06, at Cl 6-8 mg/L = 0.08, at Cl 8-10 mg/L = 0.1, at Cl >10 = 0.2

h) pH dependent dissolved Al guideline: BC Max WQG (mg/L) = 0.1 at pH ≥6.5, at pH <6.5 = EXP(1.209-2.426*(pH)+0.286*(pH2)); BC 30-d WQG (mg/L) = 0.05 at pH ≥6.5, at pH <6.5 = EXP(1.6-3.327*(median pH)+0.402*(median pH2); minimum baseline surface water pH = 5.57

i) hardness dependent dissolved Cd guideline: max BC WQG (mg/L) = (exp(1.03*ln(hardness)-5.274))/1000 BC 30-d WQG (mg/L) = (exp(0.736*ln(hardness)-4.943))/1000

j) guideline is for Cr(VI)

k) hardness dependent Cu guideline: BC Max WQG (mg/L) = (0.094(hardness)+2)/1000; BC 30-d WQG (mg/L) = 0.002 at hardness ≤50 mg/L , at hardness >50 mg/L = 0.04*hardness/1000

l) hardness dependent Pb guideline: BC Max WQG (mg/L) = 0.003 at hardness ≤8 mg/L, at hardness >8 mg/L = (EXP((1.273*ln(hardness))-1.46))/1000; BC 30-d WQG (mg/L) = (3.31+EXP(1.273(ln(hardness))-4.704))/1000 at hardness >8 mg/L, no guideline at hardness ≤8 mg/L

m) hardness dependent Mn guideline: BC Max WQG (mg/L) = 0.01102*(hardness)+0.54; BC 30-d WQG (mg/L) = 0.0044*hardness+0.605

n) BC 30-d WQG (mg/L) = 0.00002 when methylmercury (MeHg) is 0.5% of total Hg, = 0.00001 at 1% MeHg, = 0.00000125 at 8% MeHg; applied middle guideline

o) hardness dependent Ni guideline: BC 30-d WQG = 0.025 at hardness <60 mg/L, at hardness 60-120 mg/L =0.065, at hardness 120-180 mg/L = 0.11, at hardness >180 mg/L = 0.15

p) hardness dependent Ag guideline: BC Max WQG (mg/L) = 0.0001 at hardness ≤100 mg/L, at hardness >100 mg/L = 0.003; BC 30-d WQG (mg/L) = 0.00005 at hardness ≤100 mg/L, at hardness > 100 mg/L = 0.0015

q) hardness dependent Zn guideline: BC Max WQG (mg/L) = (33+0.75(hardness-90))/1000; BC 30-d WQG (mg/L) = (7.5+0.75(hardness-90))/1000

r) up to 10 - highly sensitive to acid inputs; 10 to 20 - moderately sensitive; over 20 - low sensitivity. Refer to calcium regarding sensitivity to acid inputs, the more restrictive of calcium or alkalinity is applicable.

nm - not measured

< reported value is <MDL

123	Indicates concentration exceeding the BC Max WQ Guideline
123	Indicates concentration exceeding the BC 30-d WQ Guideline
123	Indicates concentration exceeding >20% baseline (95th percentile) for parameters without BC WQGs, or parameters without BC WQGs and baseline

Table C-7: Summary of Post-Event Chromium Species Concentrations in Hazeltine Creek

Summary Statistic	Units	Upper Hazeltine Creek		Lower Hazeltine Creek	
		Trivalent Chromium	Hexavalent Chromium	Trivalent Chromium	Hexavalent Chromium
Minimum	mg/L	<0.0050	<0.001	<0.0050	*<0.001*
Median	mg/L	0.0069	<0.001	<0.0050	*<0.001*
95th Percentile	mg/L	**0.0502**	0.001435	**0.0697**	*<0.001*
Maximum	mg/L	**0.0571**	0.0016	**0.0930**	*<0.001*
# Samples	na	4	4	10	10
# Samples < MDL	na	2	3	5	10
% Samples < MDL	%	50	75	50	100

Notes:

Data summarized from HAC-05 (upper Hazeltine Creek) and HAC-01a/b (lower Hazeltine Creek). One half MDL was used for non-detect values when calculating 95th percentile concentrations.

Bold = BC MoE 30-day WQG (0.0089 mg/L for trivalent chromium; 0.001 mg/L for hexavalent chromium).

italics = MDL > BC MoE WQG

mg/L = milligrams per litre; < = less than; # = samples; MDL = method detection limit; % = percent'

BC MoE WQG = British Columbia MoE water quality guidelines for the protection of aquatic life (BC MoE 2014).

APPENDIX D

Plots of In-situ Water Quality Parameters

1.0 POLLEY LAKE

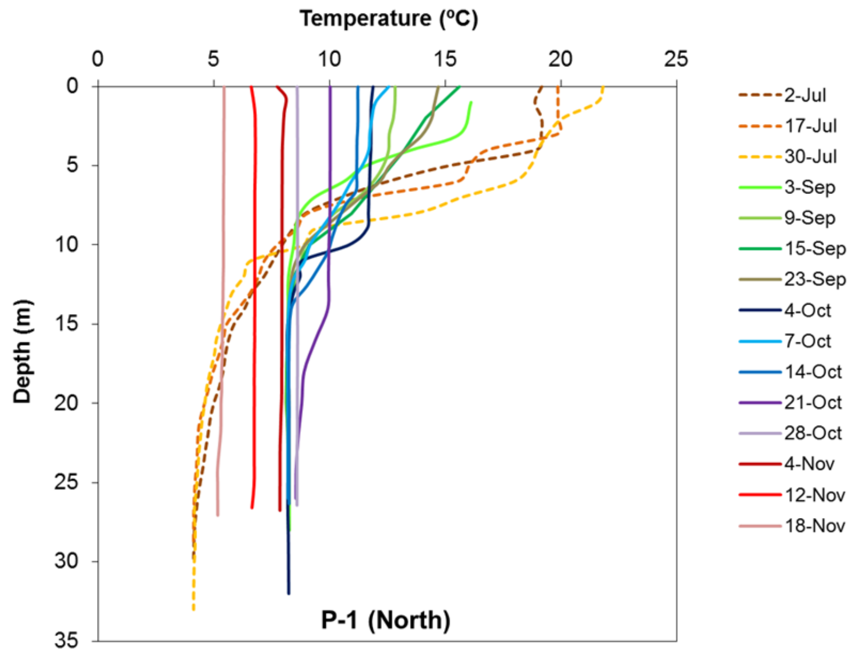

Figure 1: Depth profiles of temperature measured in-situ over time at Station P-1 in Polley Lake pre-event (July 2014) and post-event (September 2014 to November 2014).

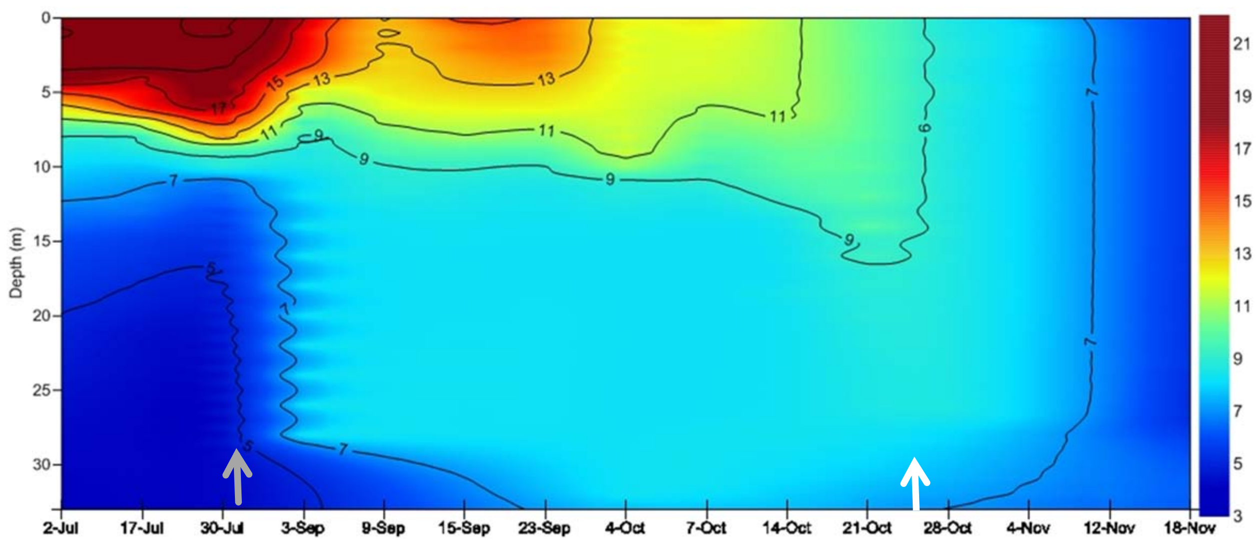

Note: The grey arrow represents the approximate timing of the event; the white arrow represents the approximate timing of late-October turnover in Polley Lake

Figure 2: Contours of temperature measured in-situ over time at Station P-1 in Polley Lake pre-event (July 2014) and post-event (September 2014 to November 2014). Temperature (°C) shown on right hand axis.

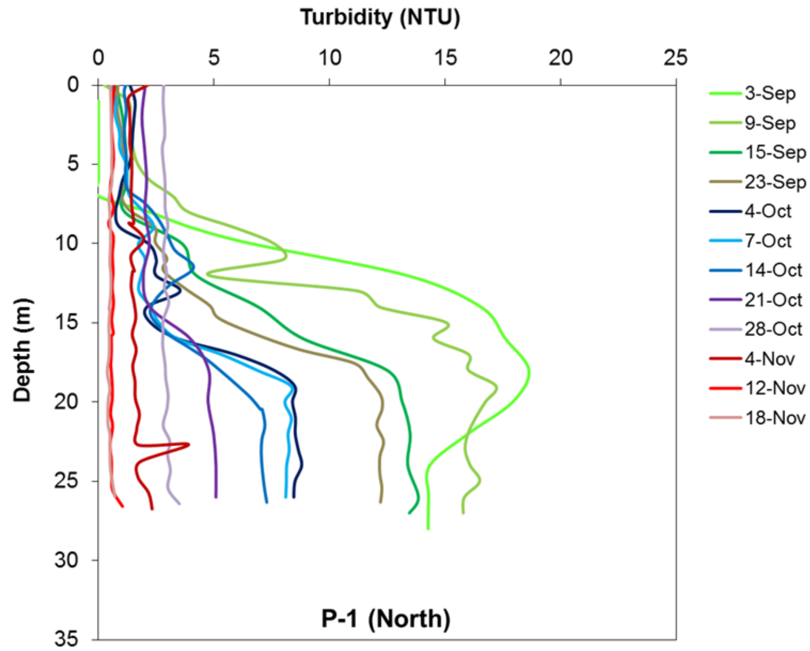

Figure 3: Depth profiles of turbidity measured in-situ over time at Station P-1 in Polley Lake post-event (September 2014 to November 2014).

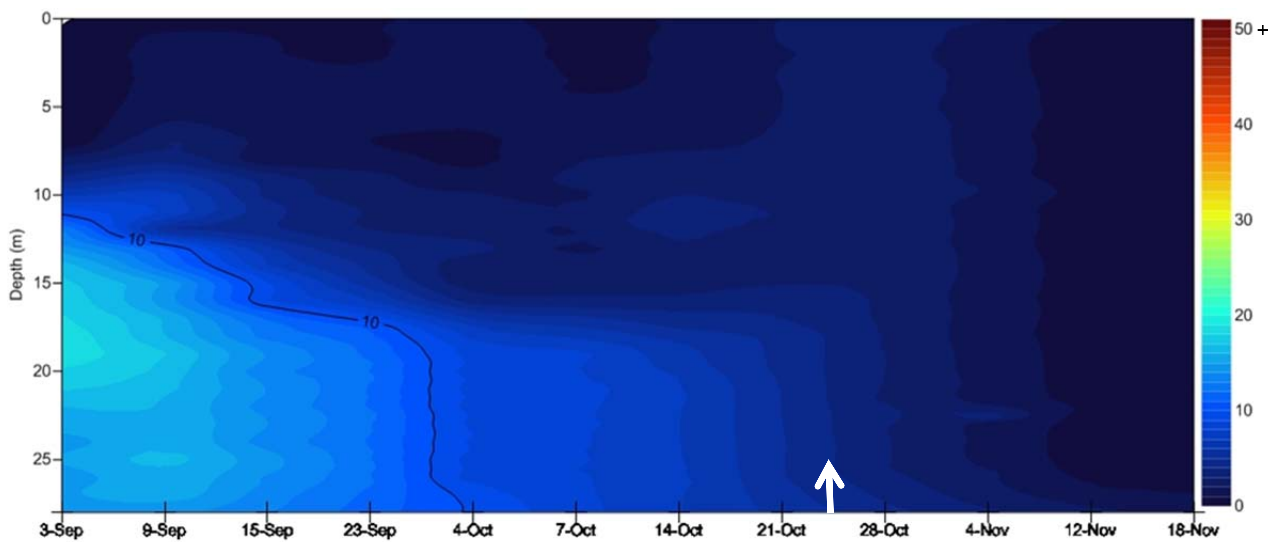

Note: The white arrow represents the approximate timing of late-October turnover in Polley Lake

Figure 4: Contours of turbidity measured in-situ over time at Station P-1 in Polley Lake and post-event (September 2014 to November 2014). Turbidity (NTU) shown on right hand axis.

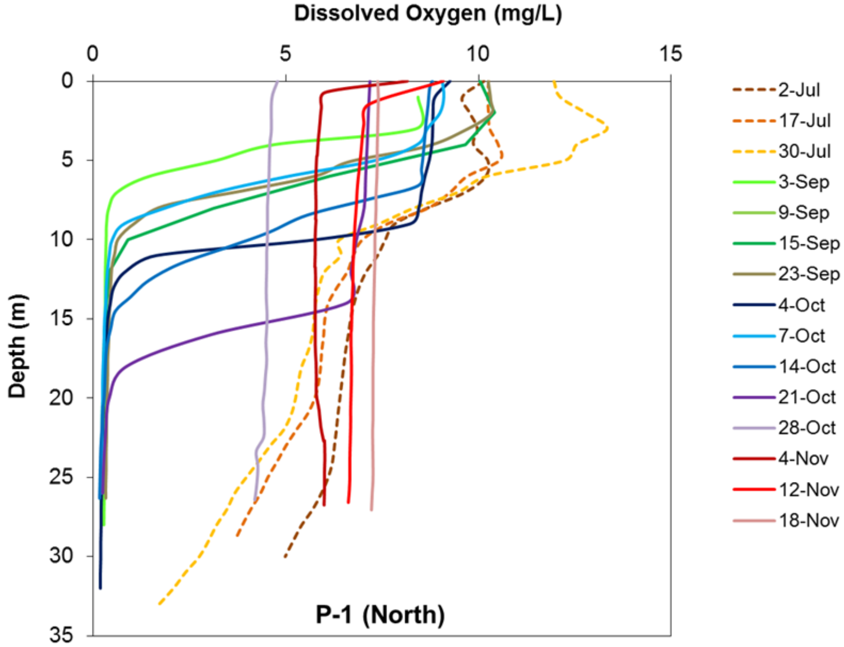

Figure 5: Depth profiles of dissolved oxygen measured in-situ over time at Station P-1 in Polley Lake pre-event (July 2014) and post-event (September 2014 to November 2014).

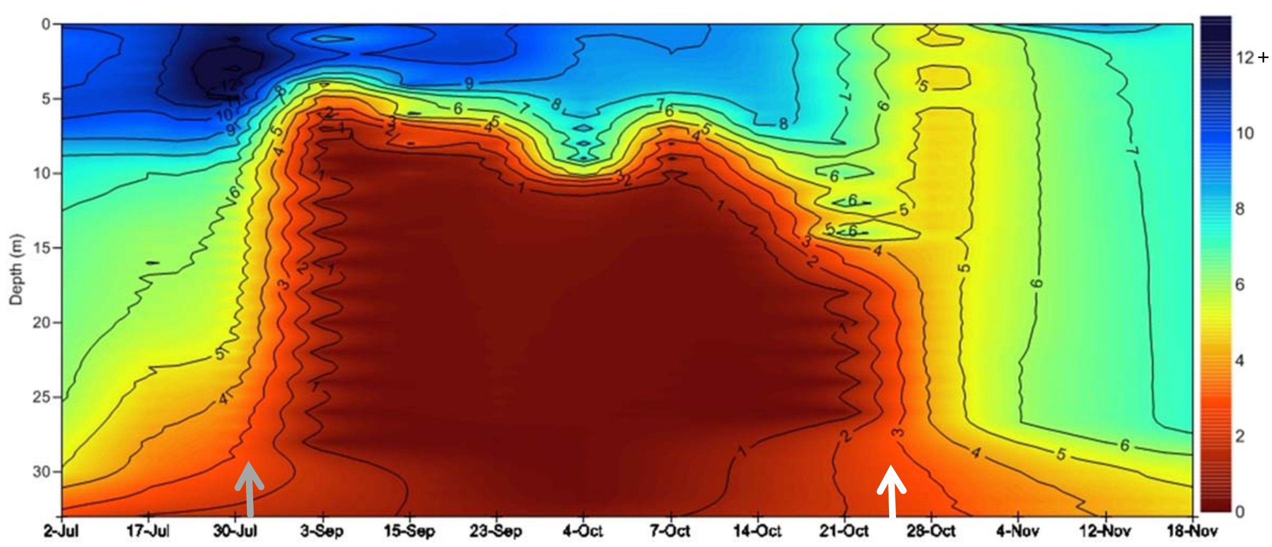

Note: The grey arrow represents the approximate timing of the event; the white arrow represents the approximate timing of late-October turnover in Polley Lake

Figure 6: Contours of dissolved oxygen measured in-situ over time at Station P-1 in Polley Lake pre-event (July 2014) and post-event (September 2014 to November 2014). Dissolved oxygen (mg/L) shown on right hand axis.

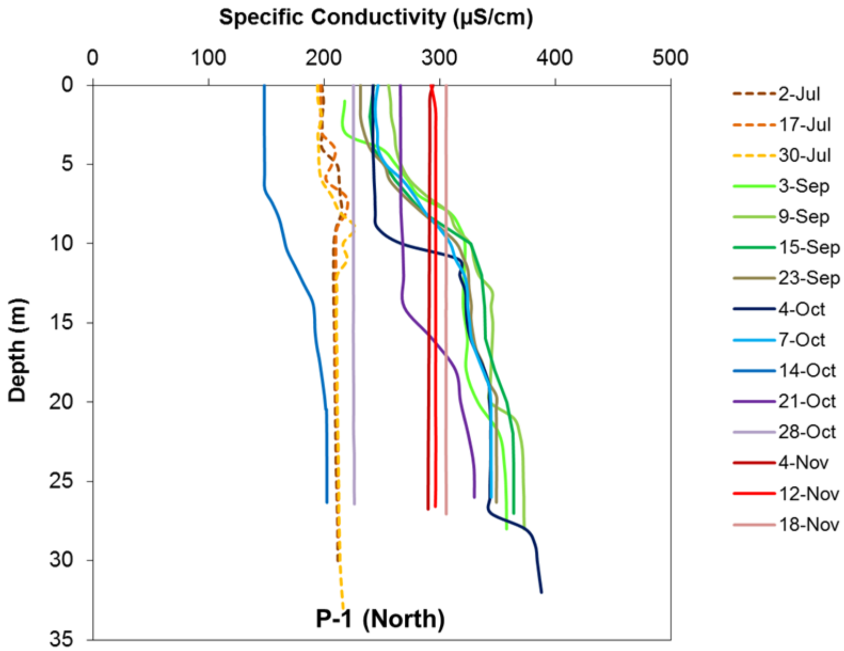

Figure 7: Depth profiles of specific conductivity measured in-situ over time at Station P-1 in Polley Lake pre-event (July 2014) and post-event (September 2014 to November 2014).

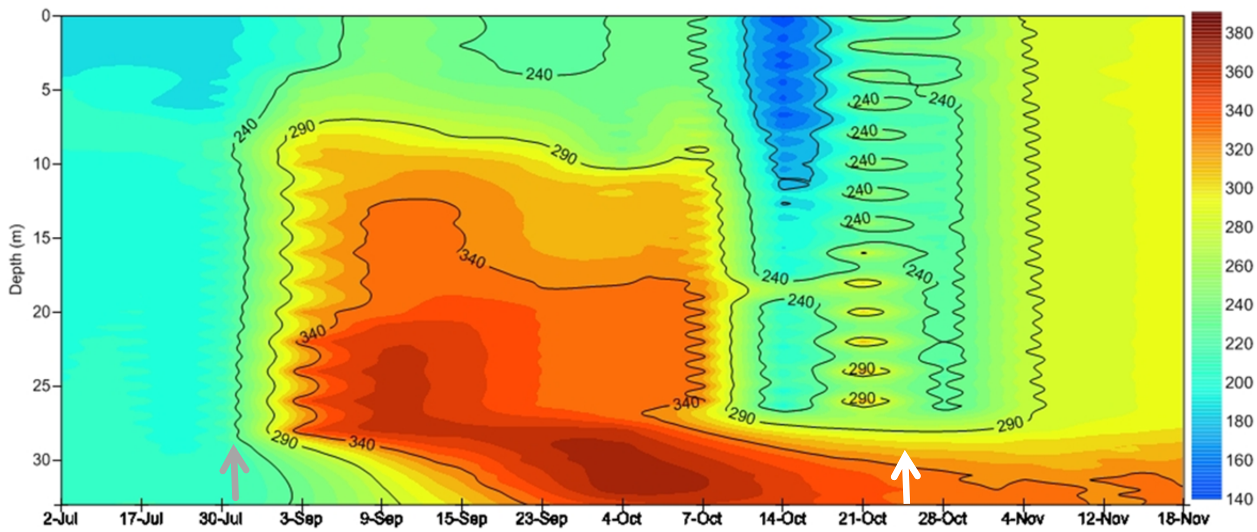

Note: The grey arrow represents the approximate timing of the event; the white arrow represents the approximate timing of late-October turnover in Polley Lake

Figure 8: Contours of specific conductivity measured in-situ over time at Station P-1 in Polley Lake pre-event (July 2014) and post-event (September 2014 to November 2014). Specific conductivity (µS/cm) shown on right hand axis.

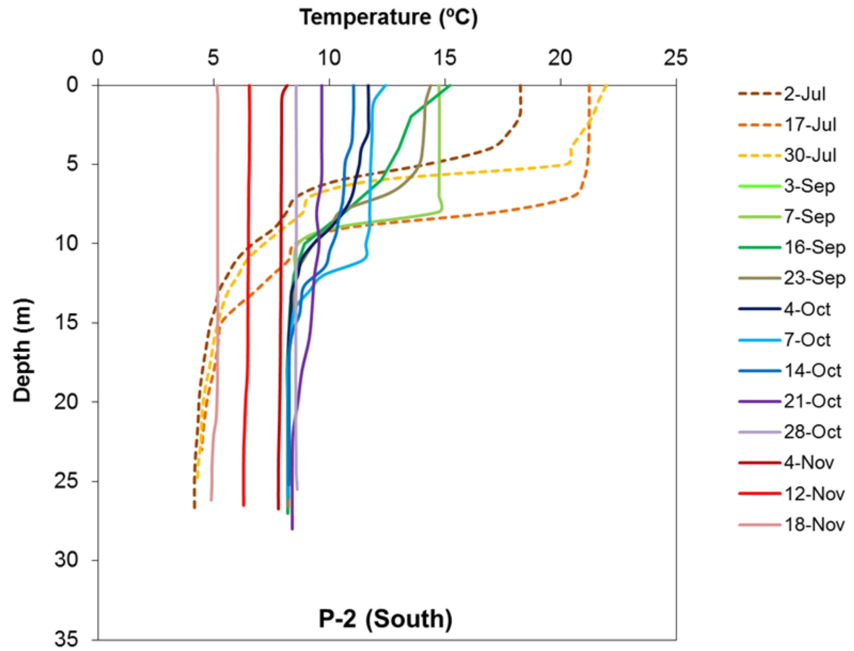

Figure 9: Depth profiles of temperature measured in-situ over time at Station P-2 in Polley Lake pre-event (July 2014) and post-event (September 2014 to November 2014).

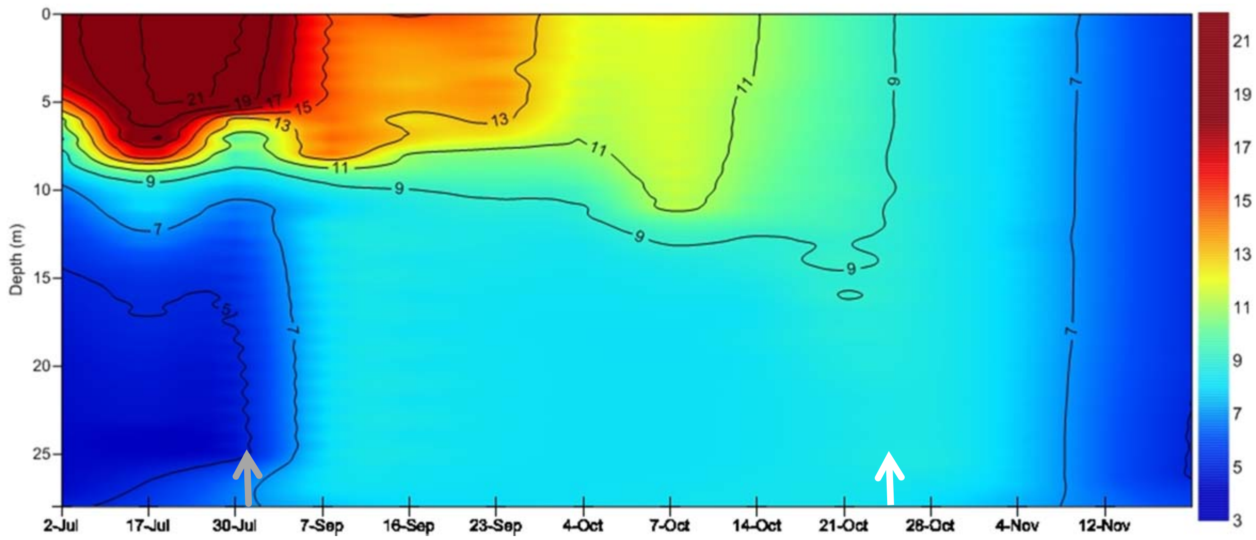

Note: The grey arrow represents the approximate timing of the event; the white arrow represents the approximate timing of late-October turnover in Polley Lake

Figure 10: Contours of temperature measured in-situ over time at Station P-2 in Polley Lake pre-event (July 2014) and post-event (September 2014 to November 2014). Temperature (°C) shown on right hand axis.

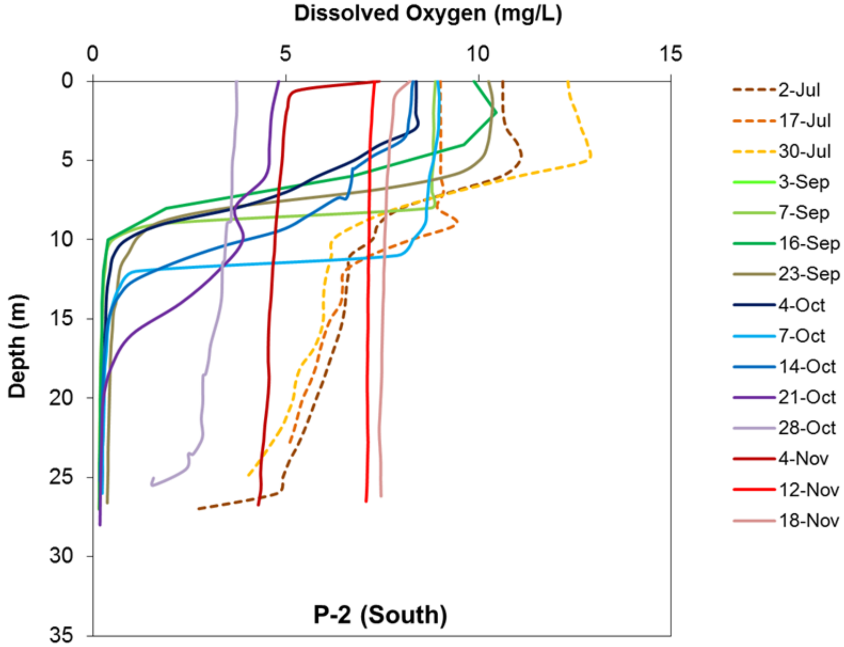

Figure 11: Depth profiles of dissolved oxygen measured in-situ over time at Station P-2 in Polley Lake pre-event (July 2014) and post-event (September 2014 to November 2014).

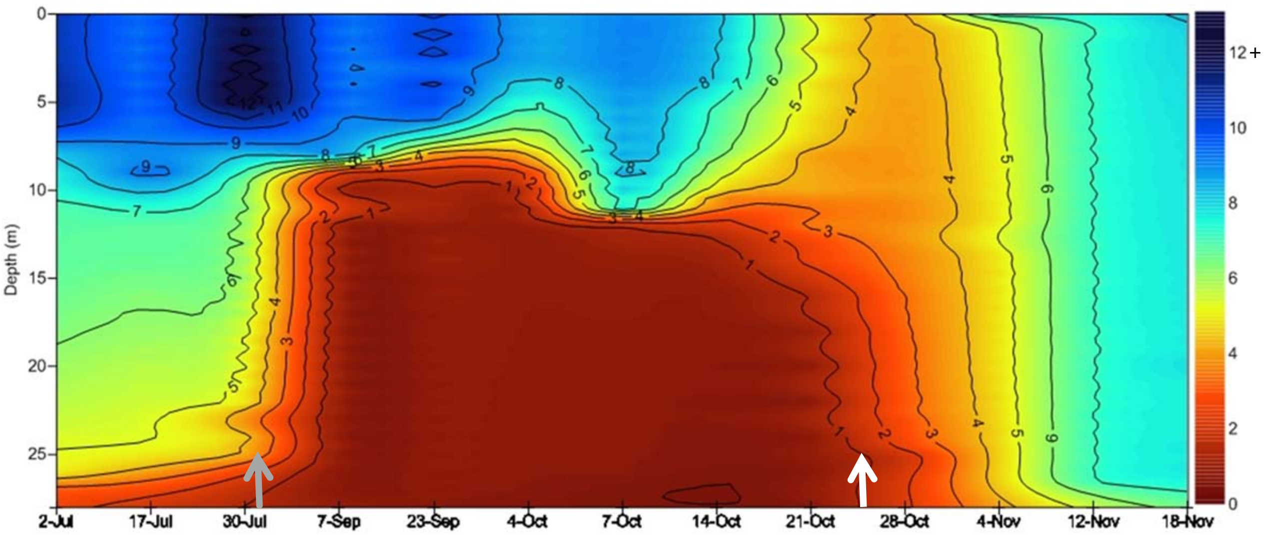

Note: The grey arrow represents the approximate timing of the event; the white arrow represents the approximate timing of late-October turnover in Polley Lake

Figure 12: Contours of dissolved oxygen measured in-situ over time at Station P-2 Polley Lake pre-event (July 2014) and post-event (September 2014 to November 2014). Dissolved oxygen (mg/L) shown on right hand axis.

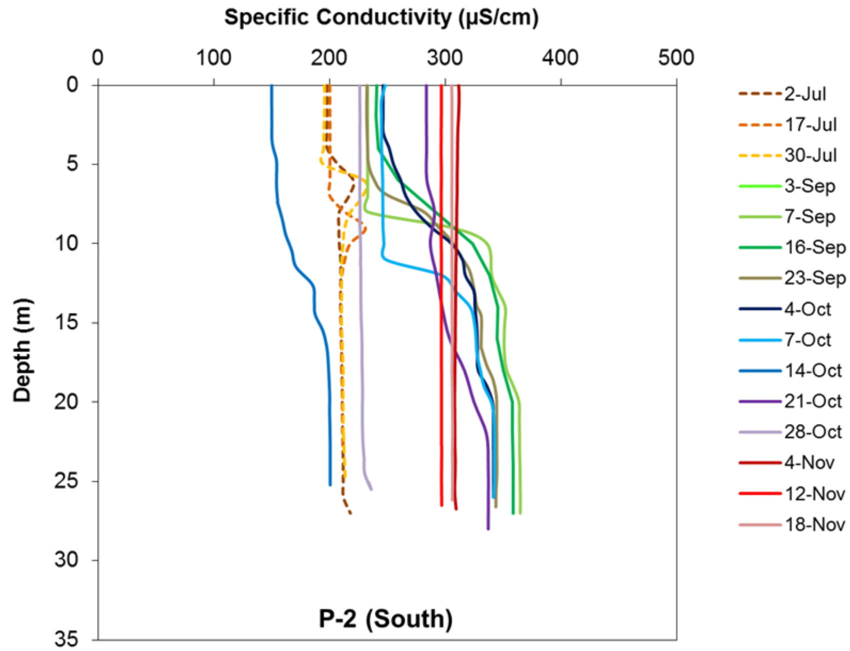

Figure 13: Depth profiles of specific conductivity measured in-situ over time at Station P-2 in Polley Lake pre-event (July 2014) and post-event (September 2014 to November 2014).

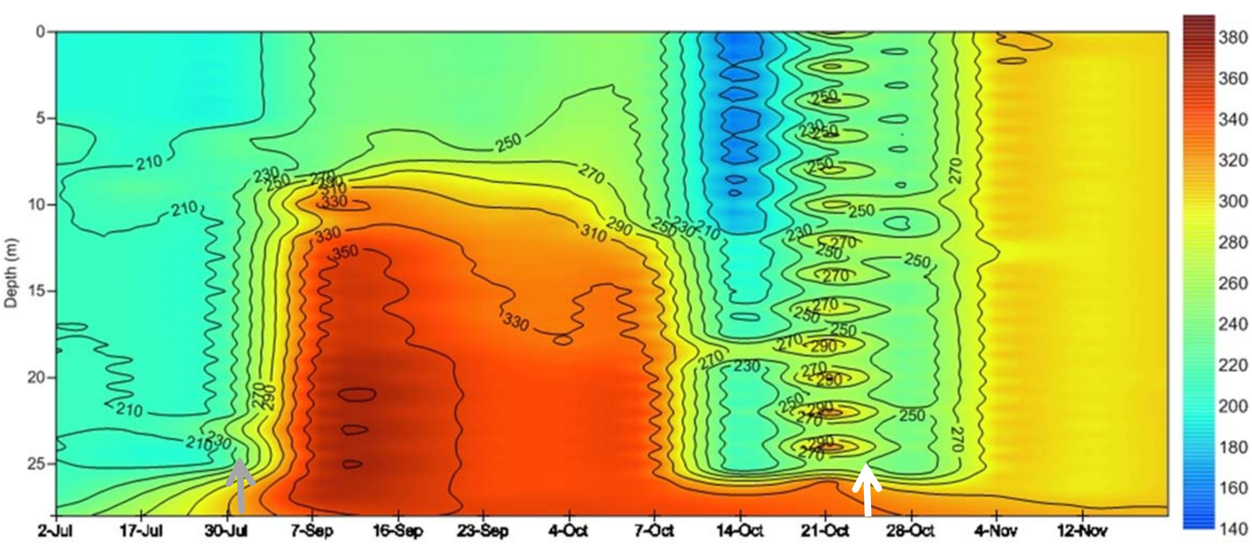
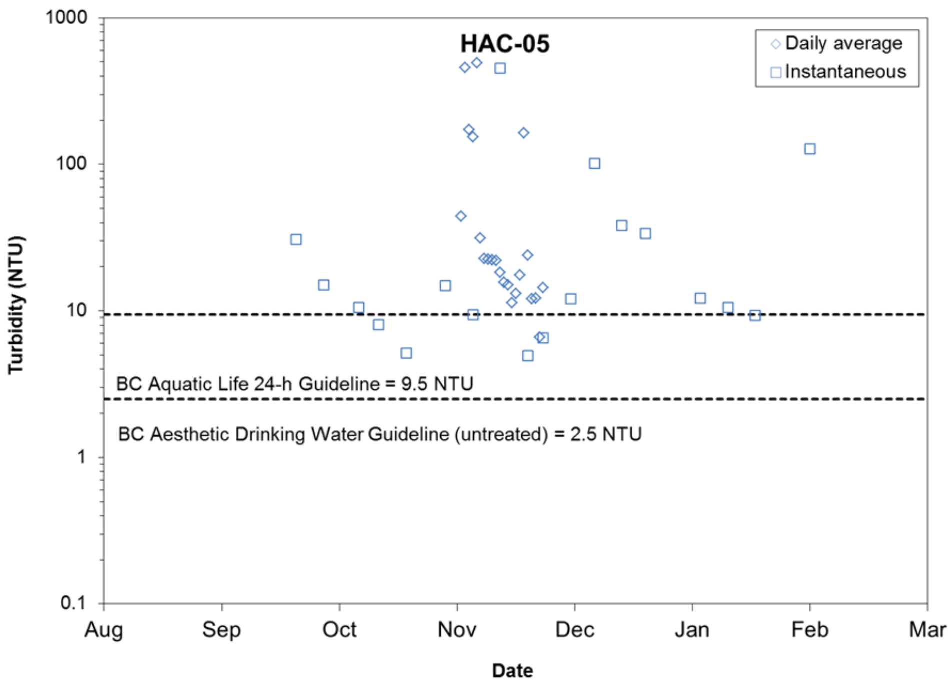


Note: The grey arrow represents the approximate timing of the event; the white arrow represents the approximate timing of late-October turnover in Polley Lake

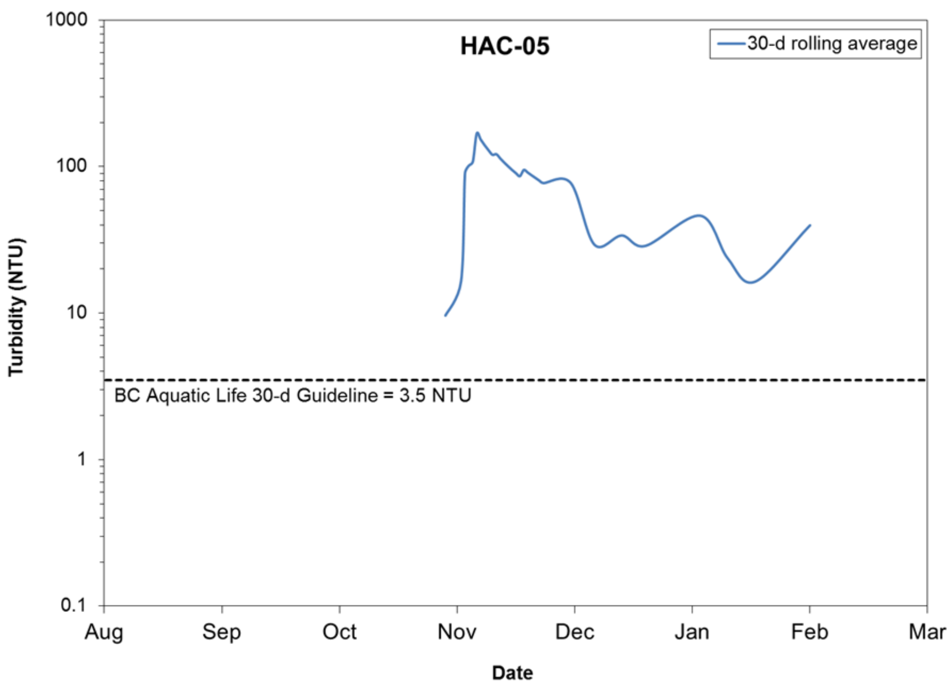
Figure 14: Contours of specific conductivity measured in-situ over time at Station P-2 in Polley Lake pre-event (July 2014) and post-event (September 2014 to November 2014). Specific conductivity (µS/cm) shown on right hand axis.

2.0 HAZELTINE CREEK



Baseline assumed equal to pre-event median baseline of 1.5 NTU.

Figure 15: Turbidity measured in-situ over time at Station HAC-05 in upper Hazeltine Creek post-event (September 2014 to February 2015).



Baseline assumed equal to pre-event median baseline of 1.5 NTU.

Figure 16: 30-day rolling average of turbidity measured in-situ over time at Station HAC-05 in upper Hazeltine Creek post-event (October 2014 to February 2015).

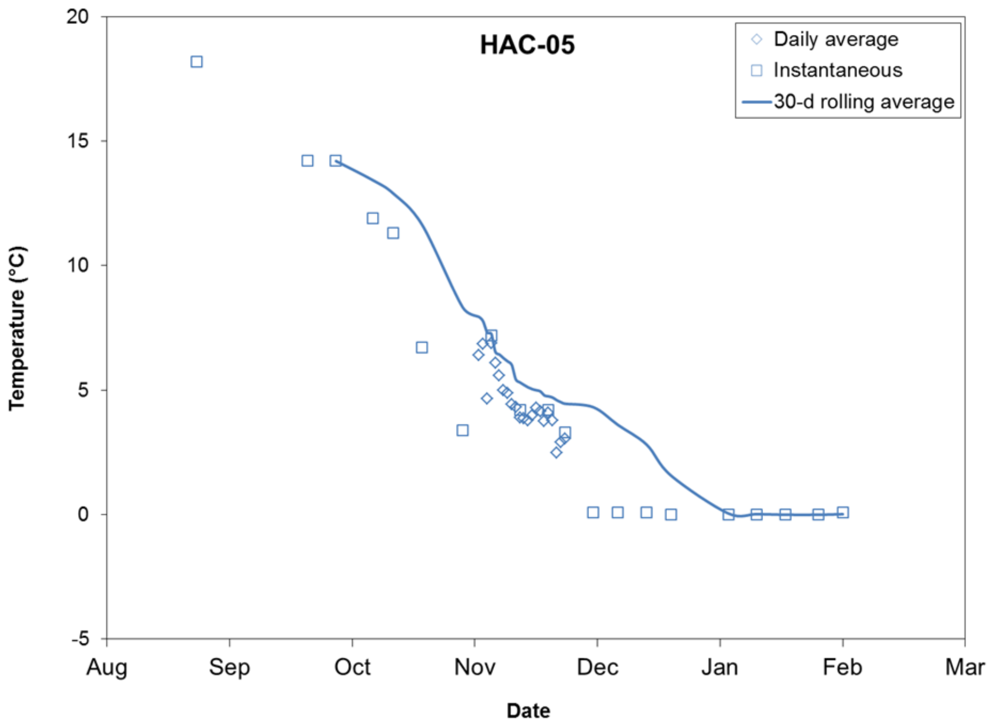


Figure 17: Temperature measured in-situ over time at Station HAC-05 in upper Hazeltine Creek post-event (August 2014 to February 2015).

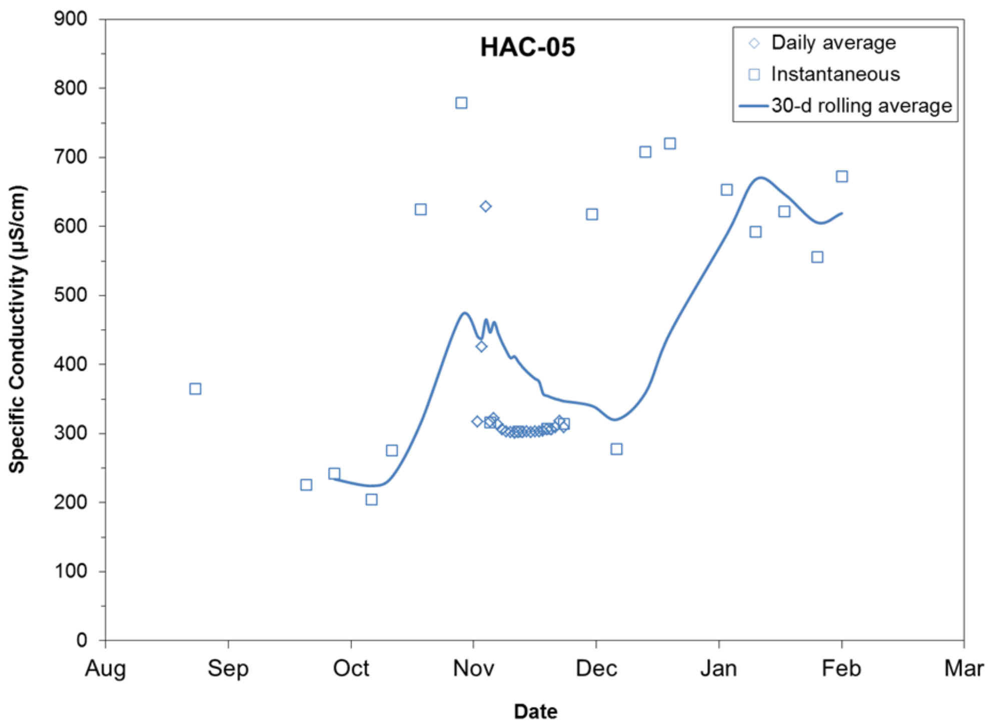

Figure 18: Specific conductivity measured in-situ over time at Station HAC-05 in upper Hazeltine Creek post-event (August 2014 to February 2015).

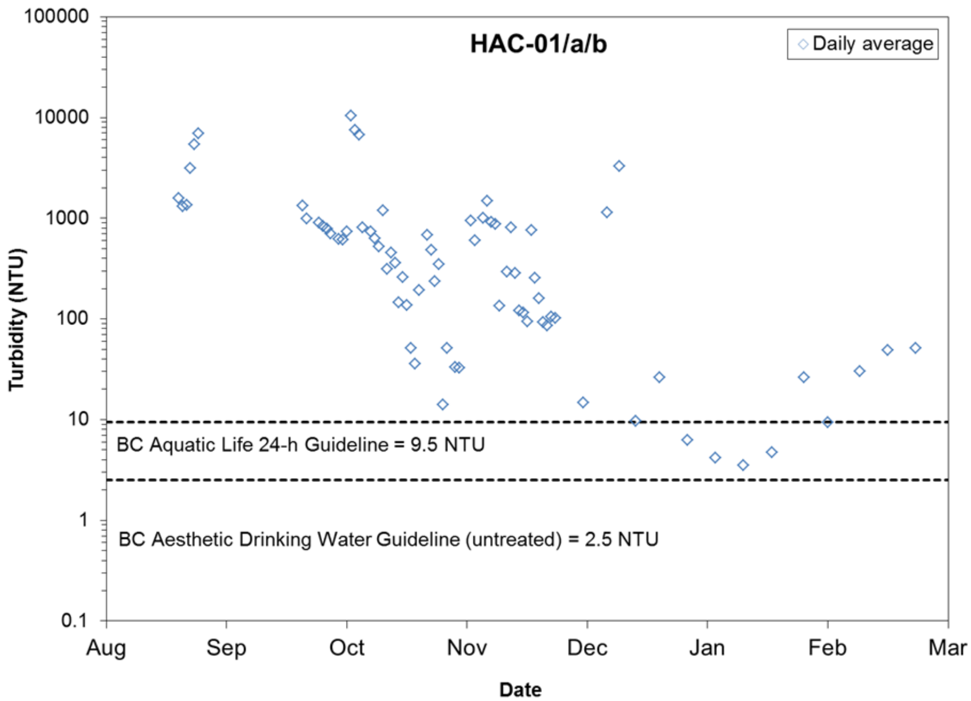
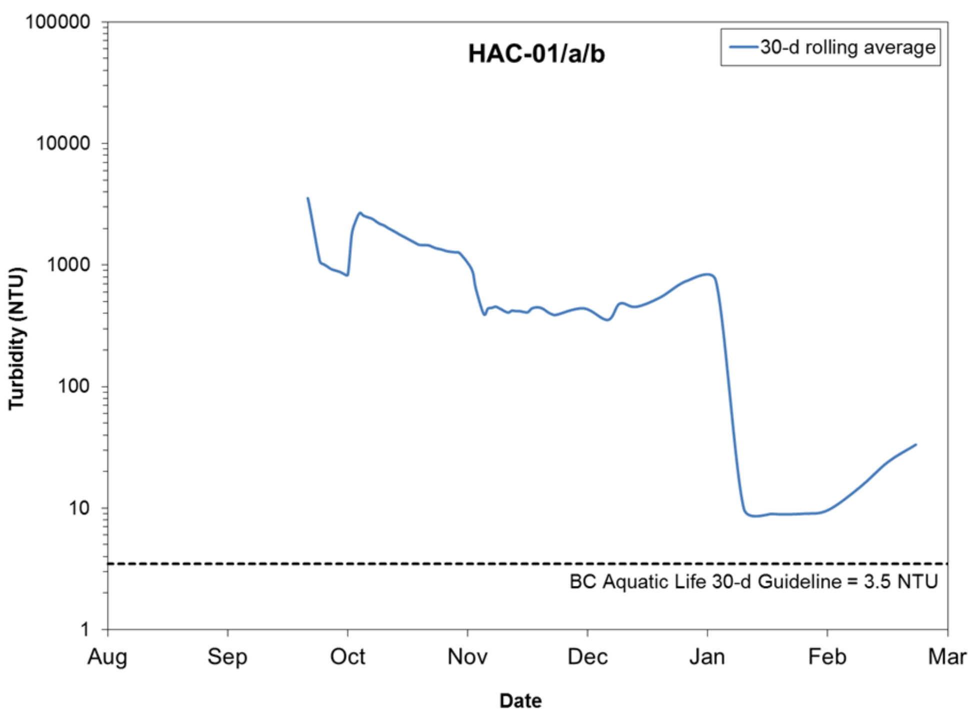


Baseline assumed equal to pre-event median baseline of 1.5 NTU.

Figure 19: Turbidity measured in-situ over time at Station HAC-01/a/b in lower Hazeltine Creek post-event (August 2014 to February 2015).



Baseline assumed equal to pre-event median baseline of 1.5 NTU.

Figure 20: 30-day rolling average of turbidity measured in-situ over time at Station HAC-01/a/b in lower Hazeltine Creek post-event (September 2014 to February 2015).

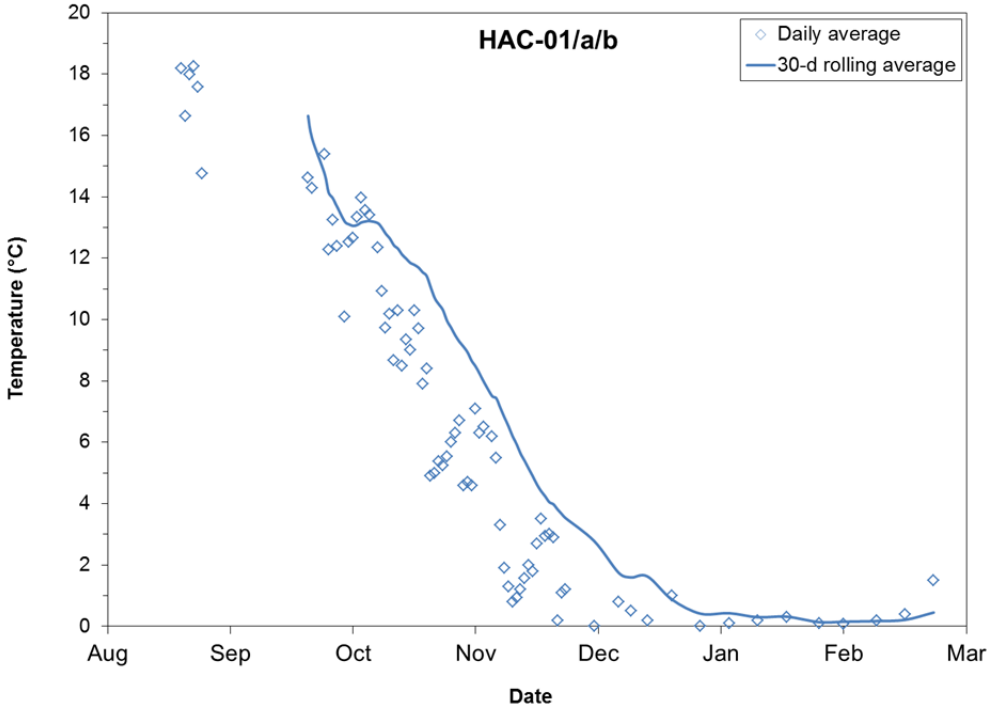


Figure 21: Temperature measured in-situ over time at Station HAC-01/a/b in lower Hazeltine Creek post-event (August 2014 to February 2015).

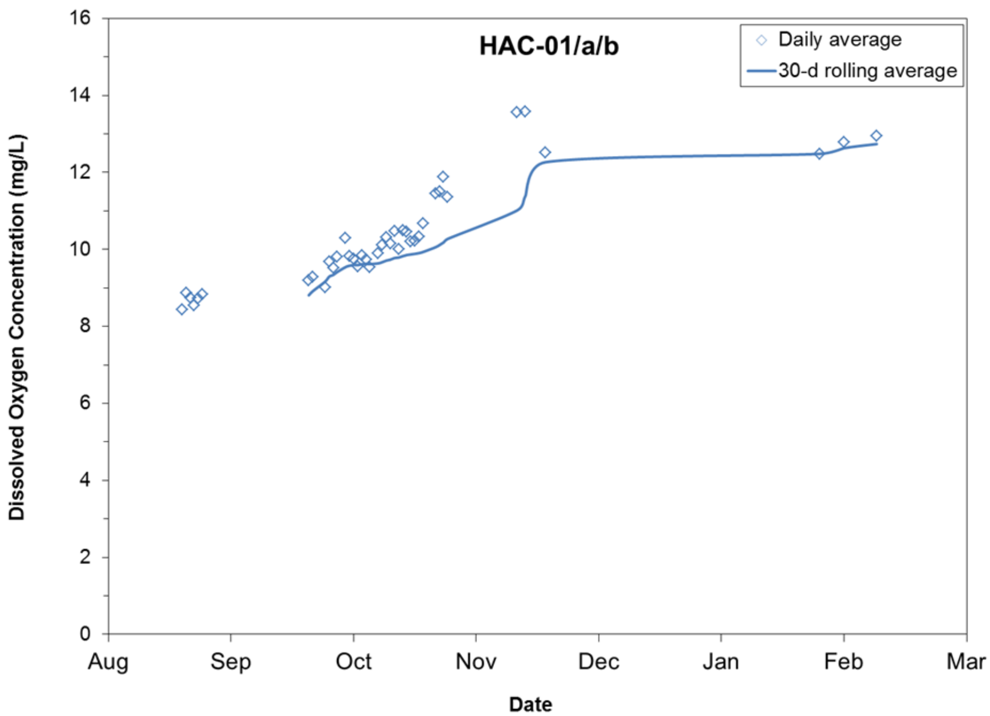

Figure 22: Concentration of dissolved oxygen measured in-situ over time at Station HAC-01/a/b in lower Hazeltine Creek post-event (August 2014 to February 2015).

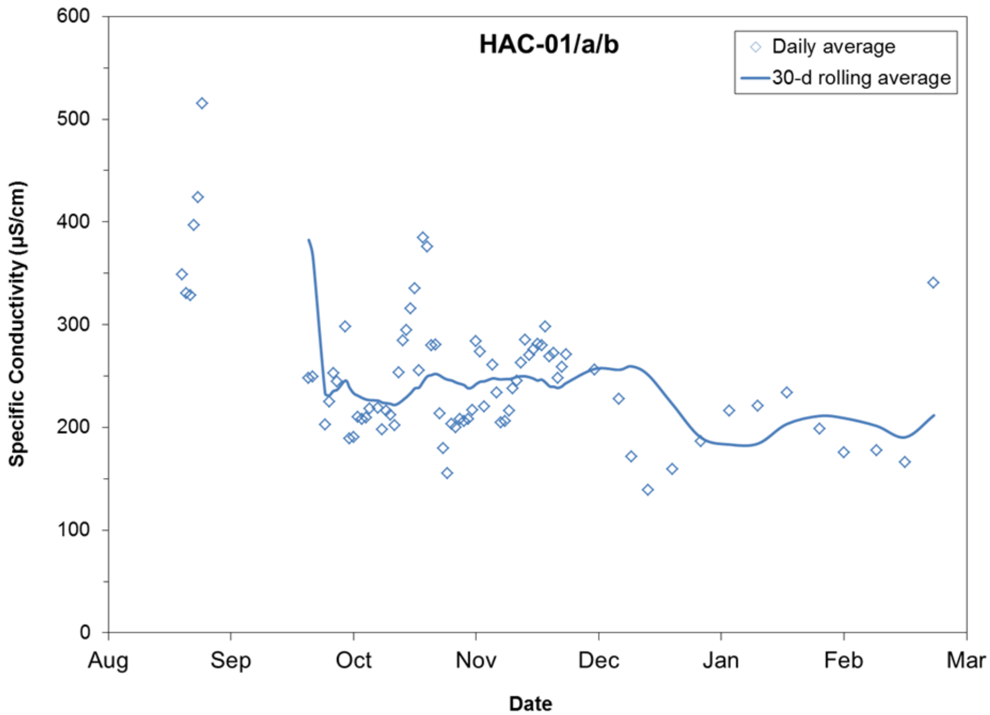

Figure 23: Specific conductivity measured in-situ over time at Station HAC-01/a/b in lower Hazeltine Creek post-event (August 2014 to February 2015).

3.0 QUESNEL LAKE

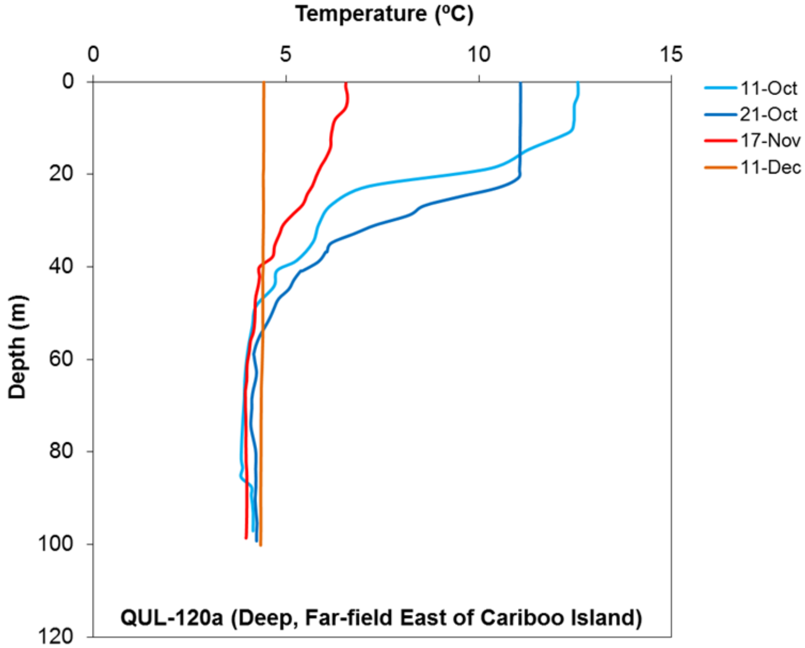

Figure 24: Depth profiles of temperature measured in-situ over time at Station QUL-120a in Quesnel Lake post-event (October 2014 to December 2014).

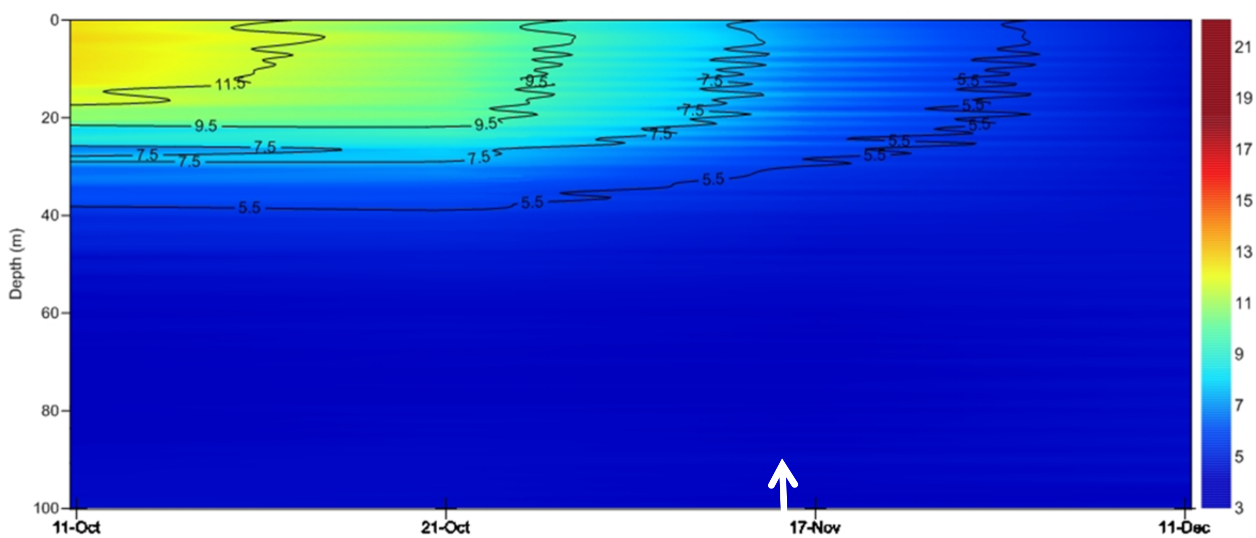

Note: The white arrow represents the approximate timing of mid-November turnover in Quesnel Lake

Figure 25: Contours of temperature measured in-situ over time at Station QUL-120a in Quesnel Lake post-event (October 2014 to December 2014). Temperature (°C) shown on right hand axis.

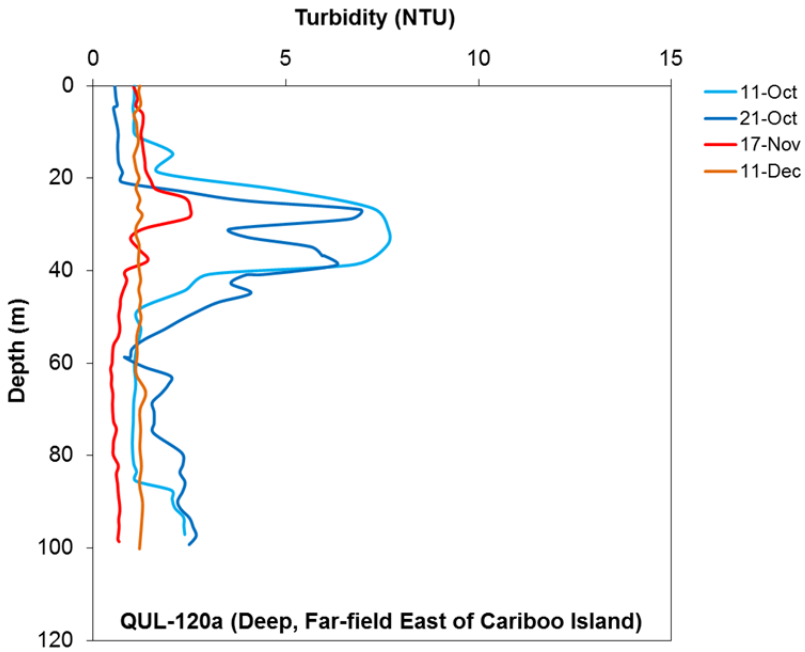

Figure 26: Depth profiles of turbidity measured in-situ over time at Station QUL-120a in Quesnel Lake post-event (October 2014 to December 2014).

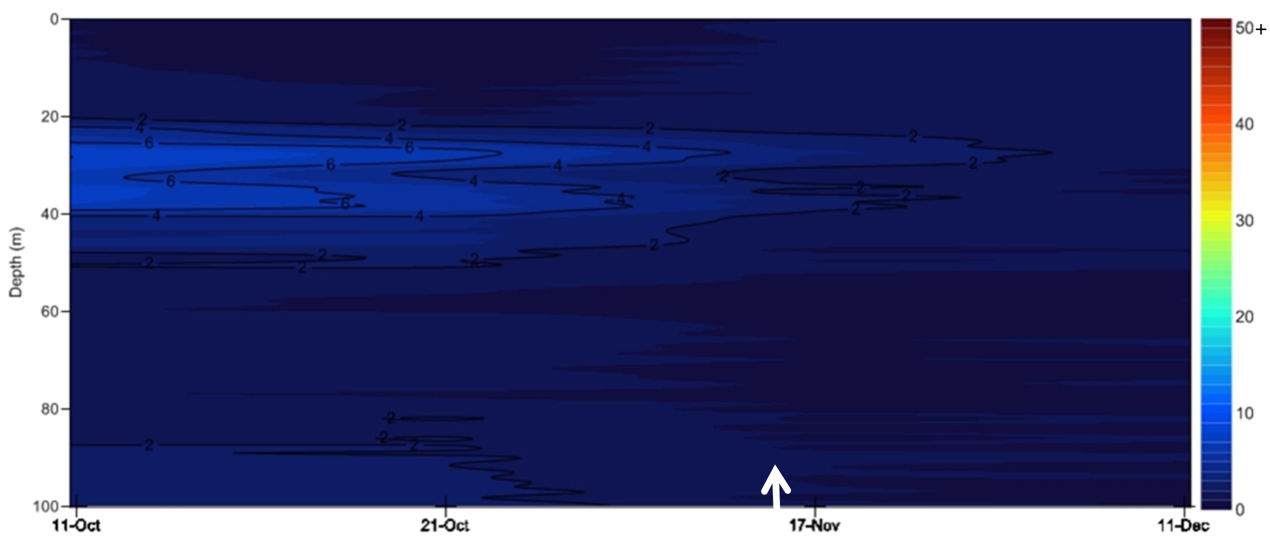

Note: The white arrow represents the approximate timing of mid-November turnover in Quesnel Lake

Figure 27: Contours of turbidity measured in-situ over time at Station QUL-120a in Quesnel Lake post-event (October 2014 to December 2014). Turbidity (NTU) shown on right hand axis.

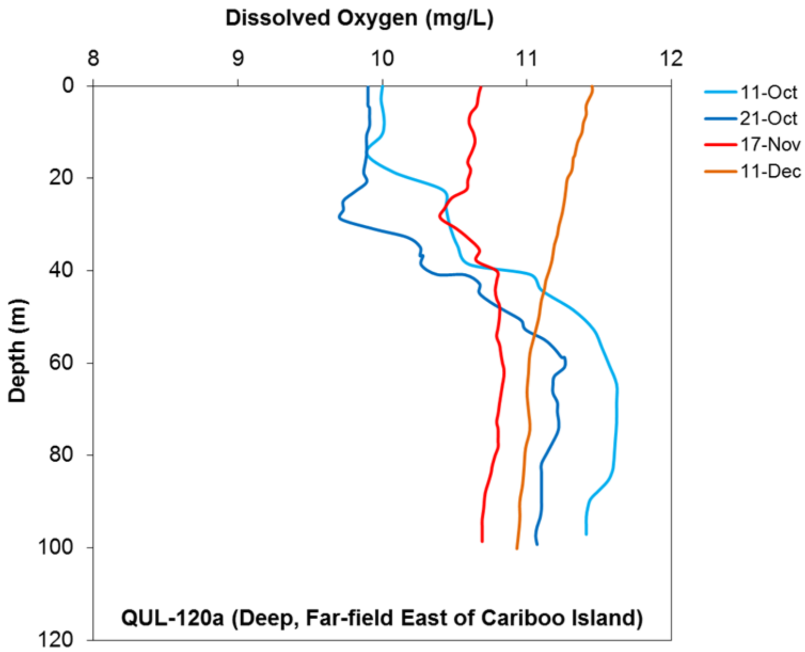

Figure 28: Depth profiles of dissolved oxygen measured in-situ over time at Station QUL-120a in Quesnel Lake post-event (October 2014 to December 2014).

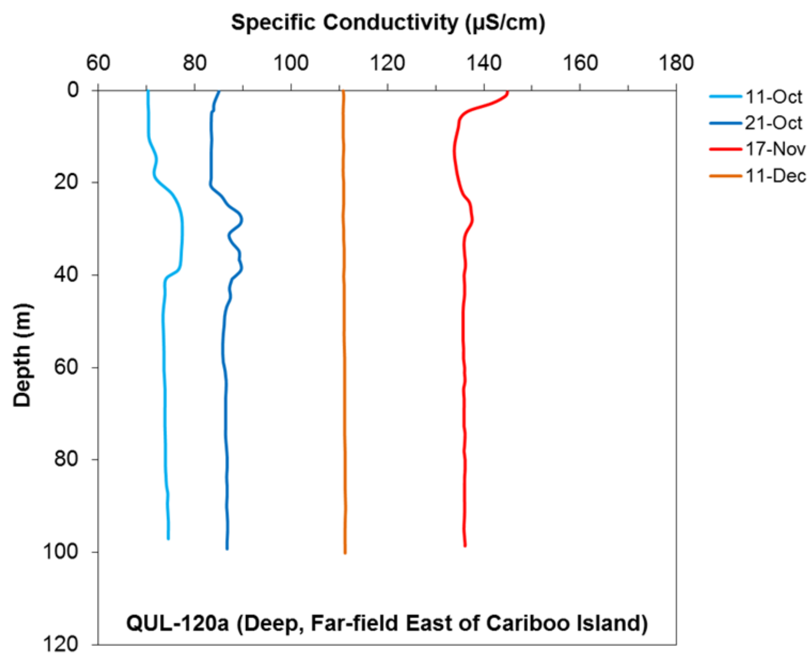

Figure 29: Depth profiles of specific conductivity measured in-situ over time at Station QUL-120a in Quesnel Lake post-event (October 2014 to December 2014).

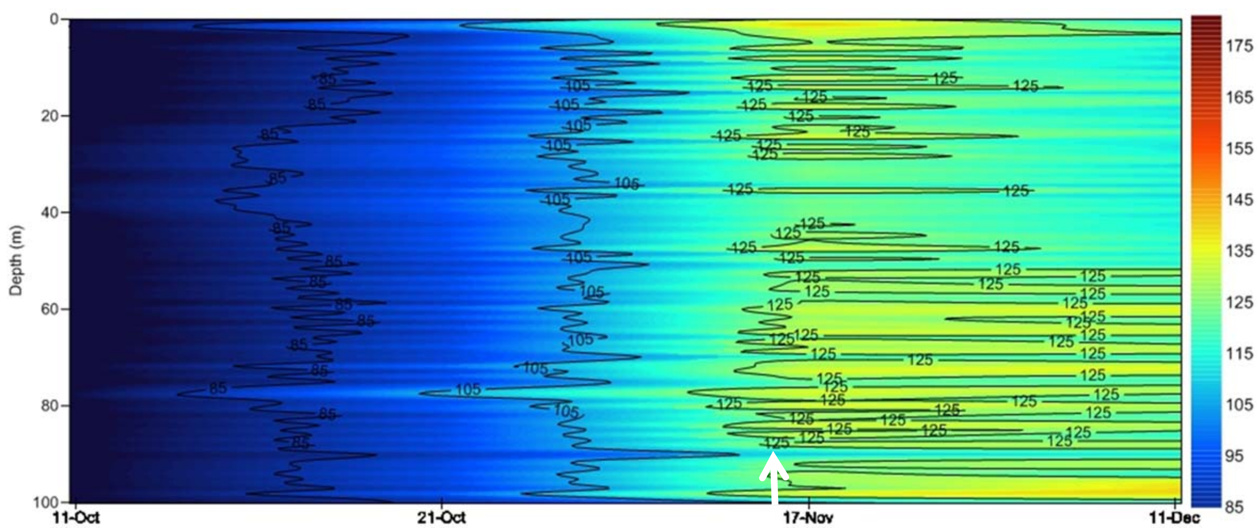
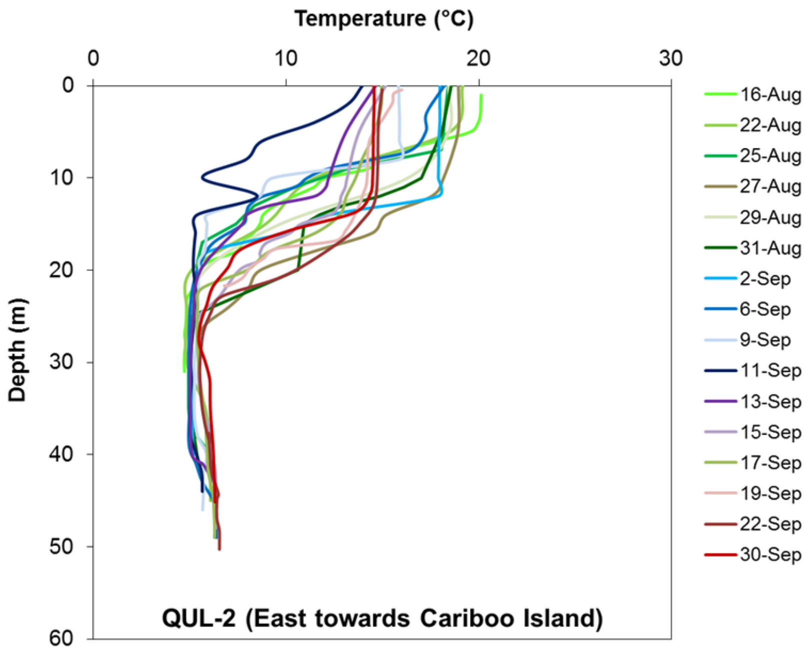


Note: The white arrow represents the approximate timing of mid-November turnover in Quesnel Lake

Figure 30: Contours of specific conductivity measured in-situ over time at Station QUL-120a in Quesnel Lake post-event (October 2014 to December 2014). Specific conductivity (µS/cm) shown on right hand axis.



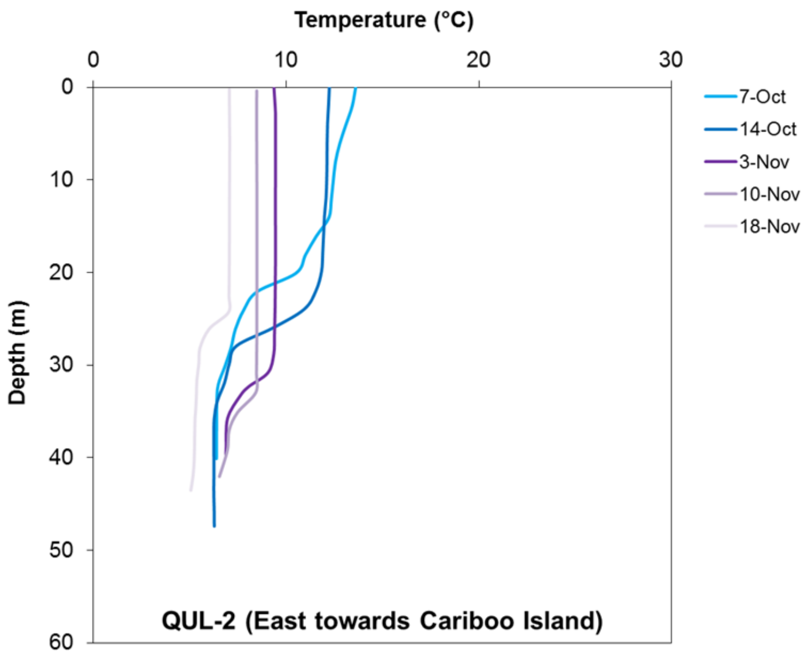


Figure 31: Depth profiles of temperature measured in-situ over time at Station QUL-2 in Quesnel Lake post-event (August 2014 to November 2014).

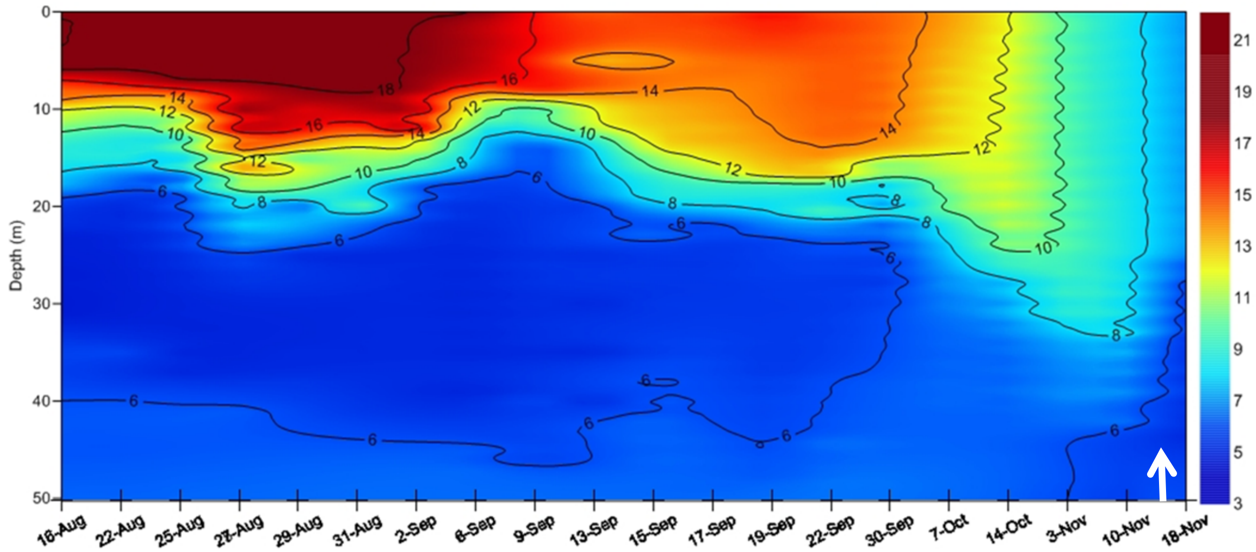
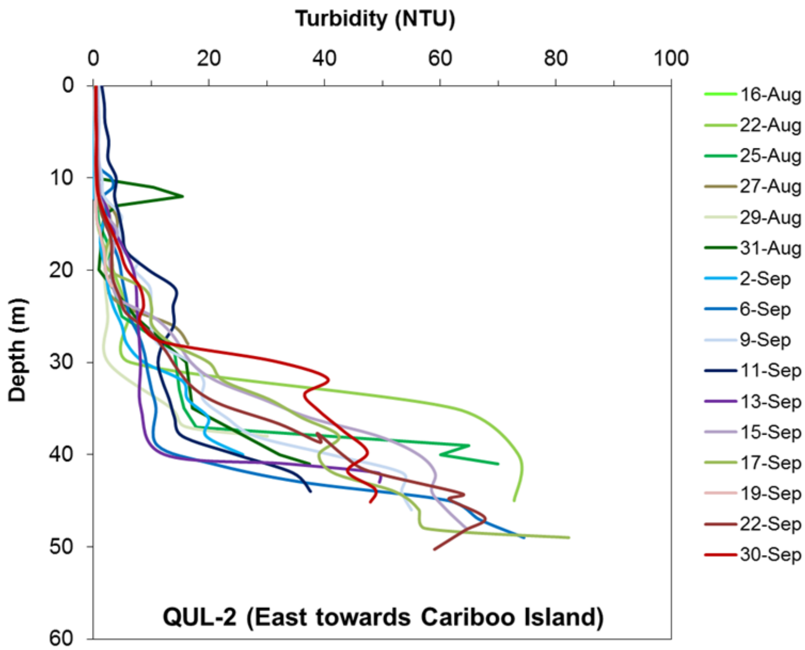


Note: The white arrow represents the approximate timing of mid-November turnover in Quesnel Lake

Figure 32: Contours of temperature measured in-situ over time at Station QUL-2 in Quesnel Lake post-event (August 2014 to November 2014). Temperature (°C) shown on right hand axis.



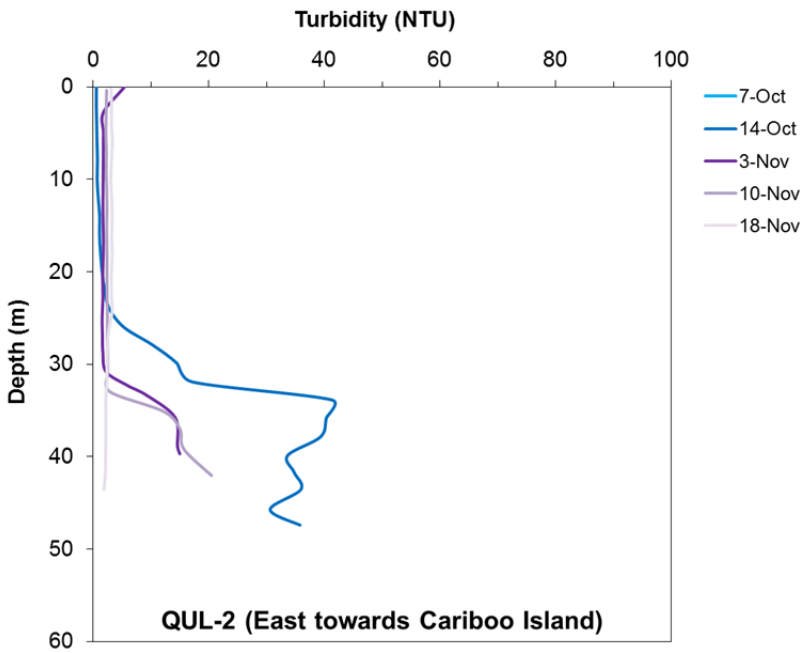


Figure 33: Depth profiles of turbidity measured in-situ over time at Station QUL-2 in Quesnel Lake post-event (August 2014 to November 2014).

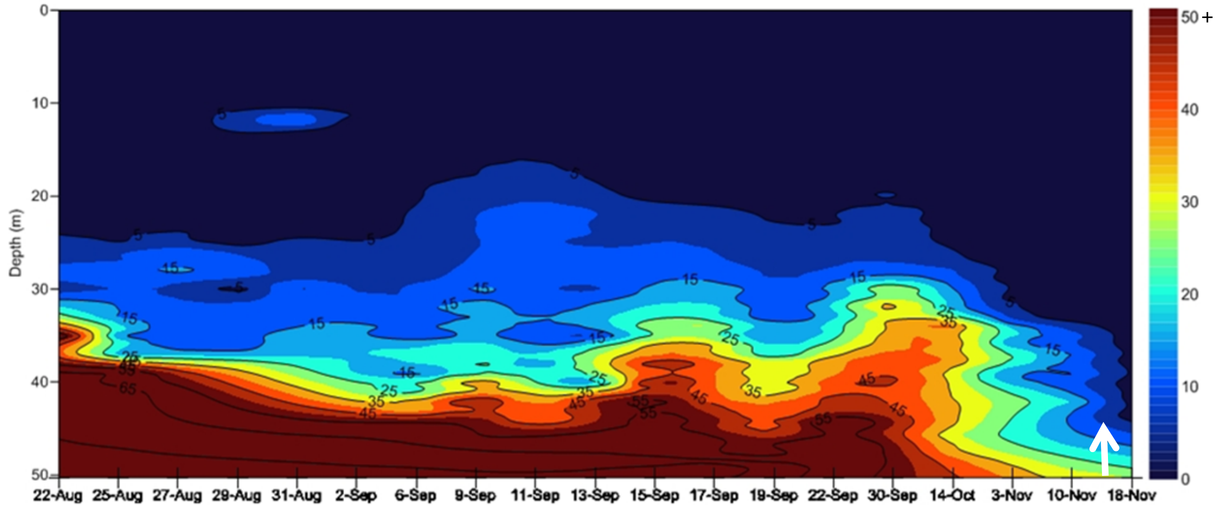
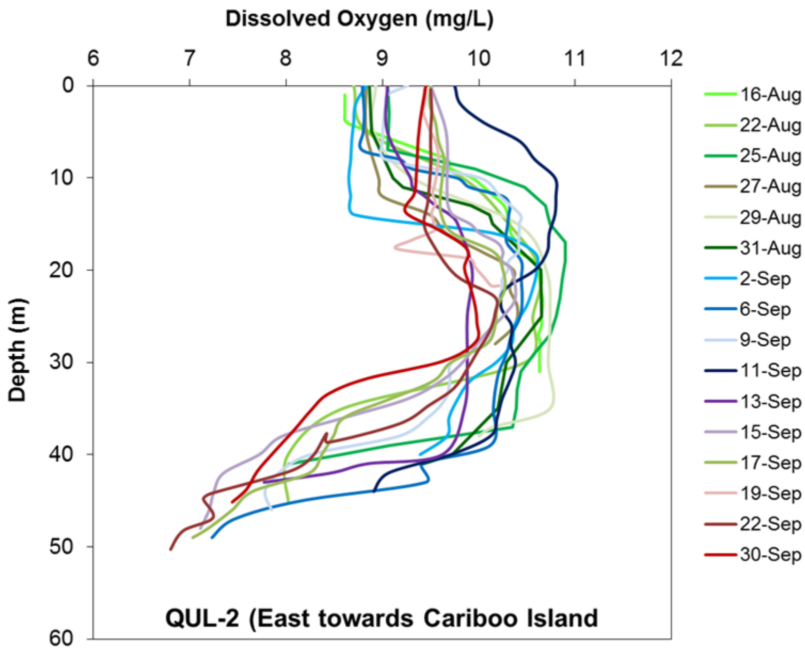


Note: The white arrow represents the approximate timing of mid-November turnover in Quesnel Lake

Figure 34: Contours of turbidity measured in-situ over time at Station QUL-2 in Quesnel Lake post-event (August 2014 to November 2014). Turbidity (NTU) shown on right hand axis.



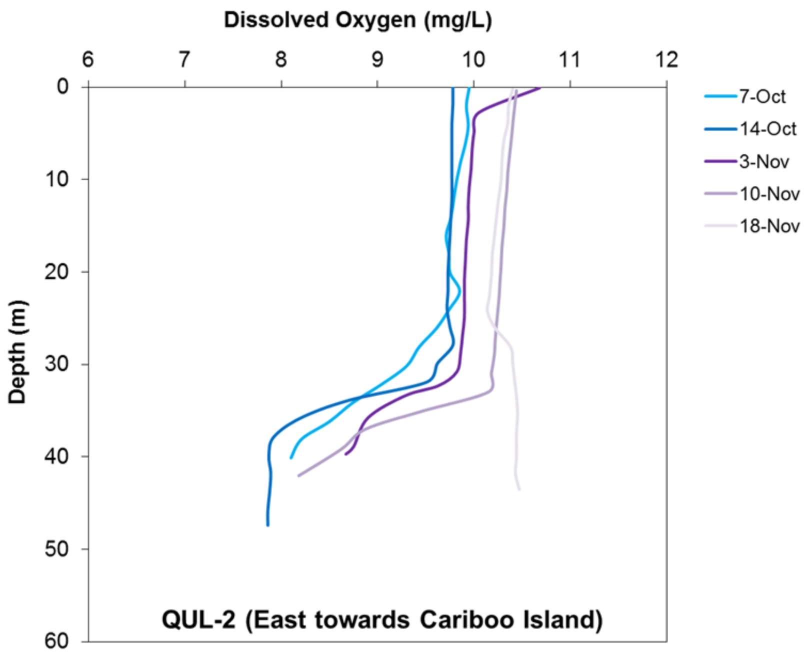


Figure 35: Depth profiles of dissolved oxygen measured in-situ over time at Station QUL-2 in Quesnel Lake post-event (August 2014 to November 2014).

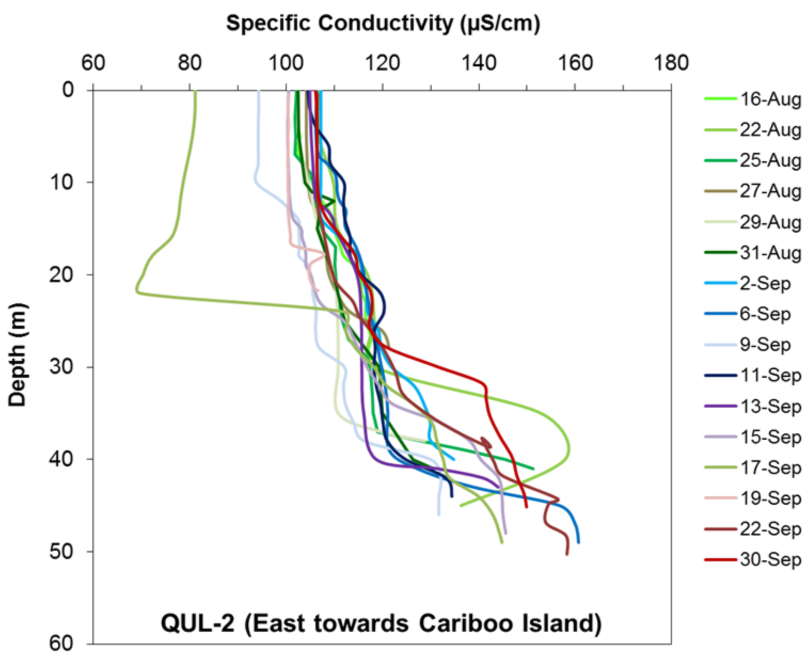

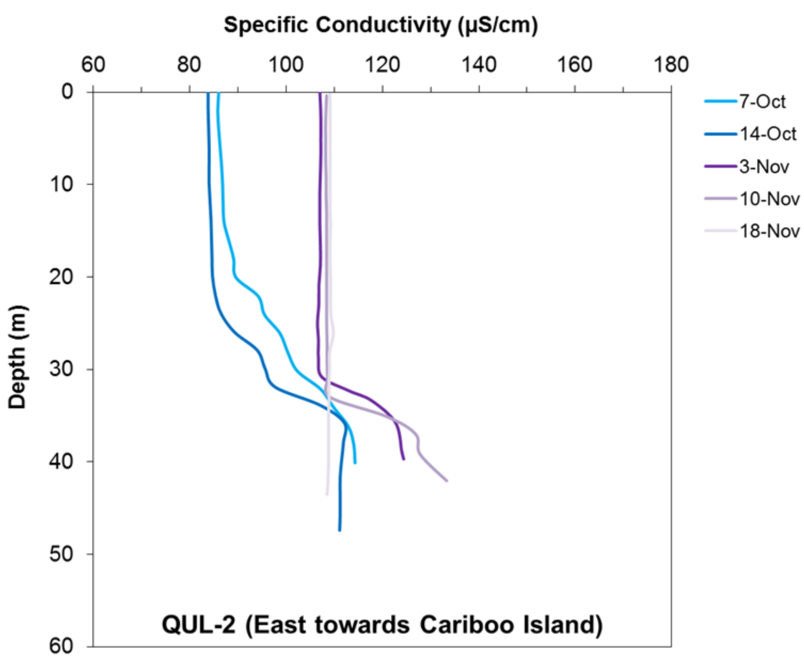

Figure 36: Depth profiles of specific conductivity measured in-situ over time at Station QUL-2 in Quesnel Lake post-event (August 2014 to November 2014).

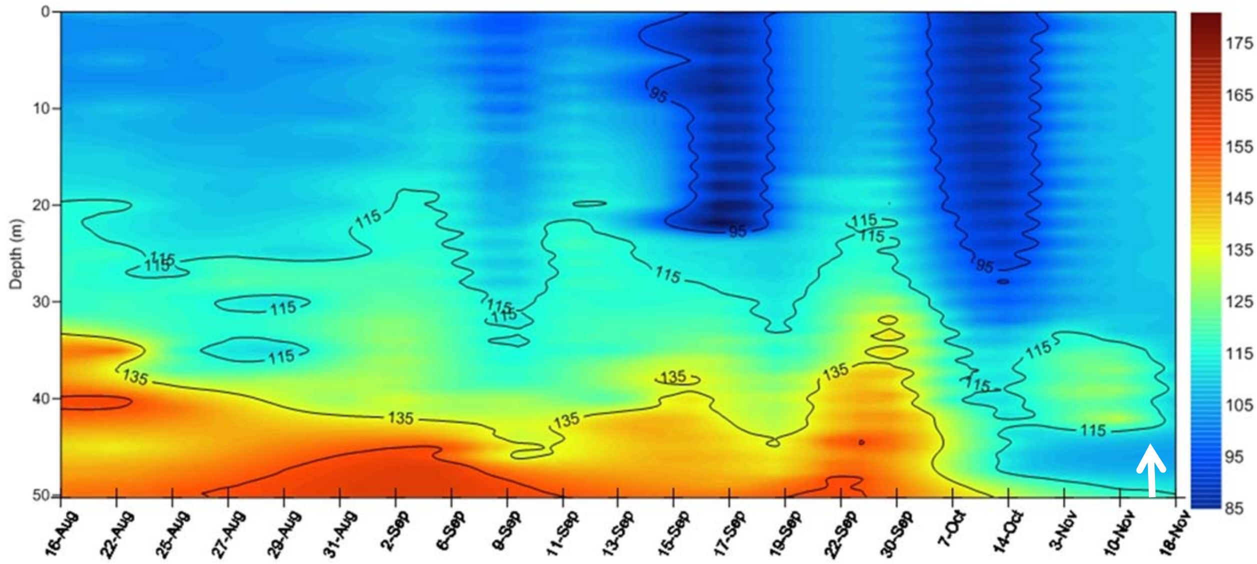
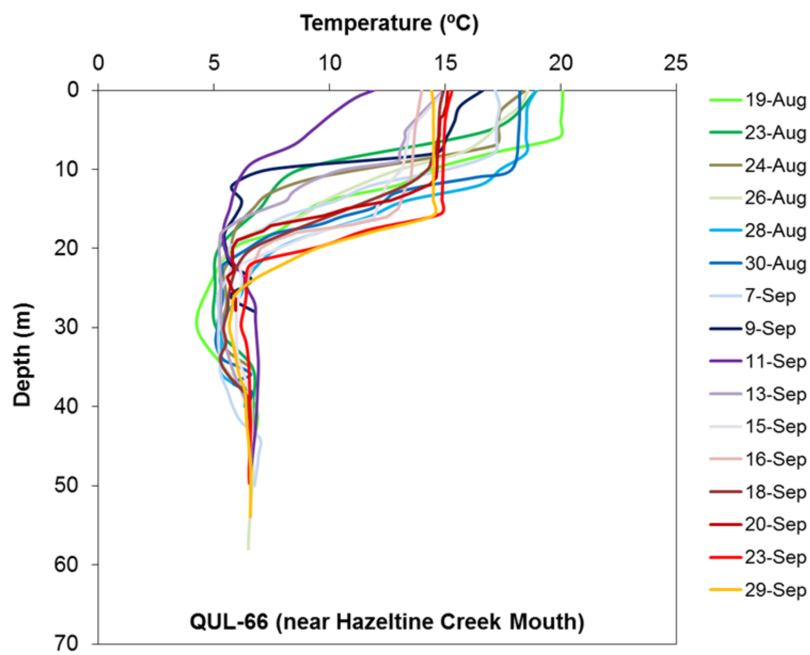


Note: The white arrow represents the approximate timing of mid-November turnover in Quesnel Lake

Figure 37: Contours of specific conductivity measured in-situ over time at Station QUL-2 in Quesnel Lake post-event (August 2014 to November 2014). Specific conductivity (µS/cm) shown on right hand axis.



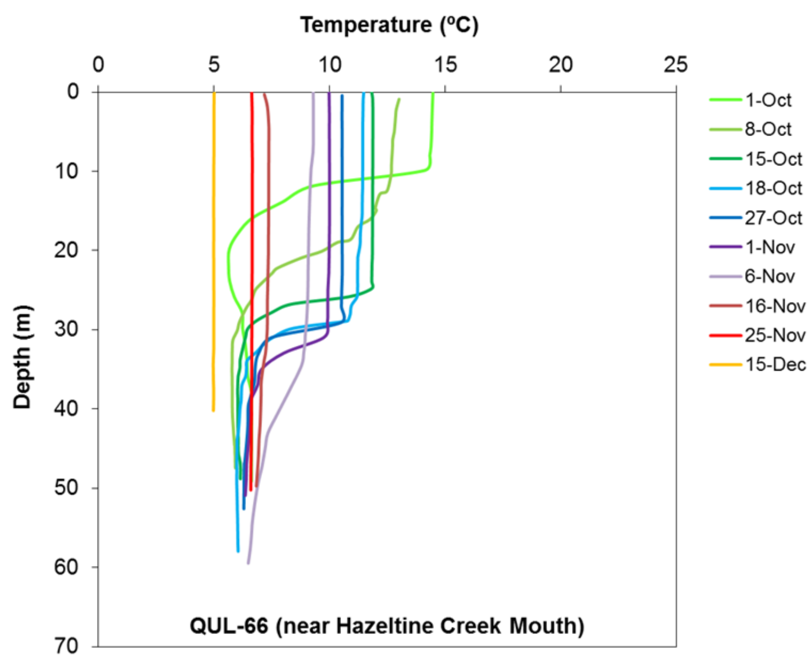


Figure 38: Depth profiles of temperature measured in-situ over time at Station QUL-66 in Quesnel Lake post-event (August 2014 to December 2014).

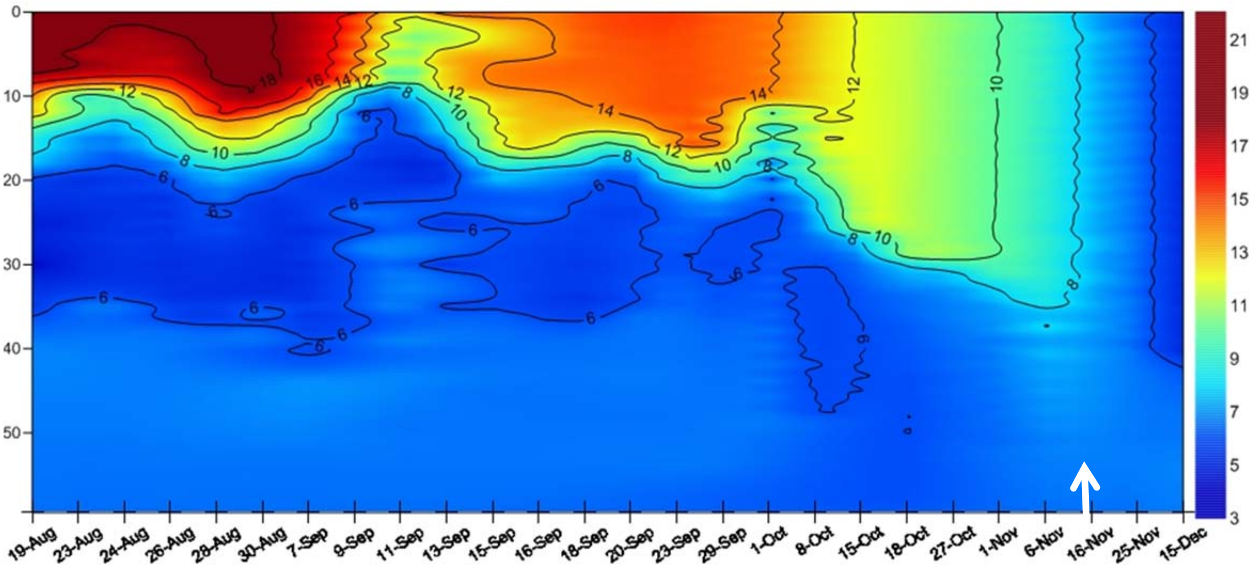
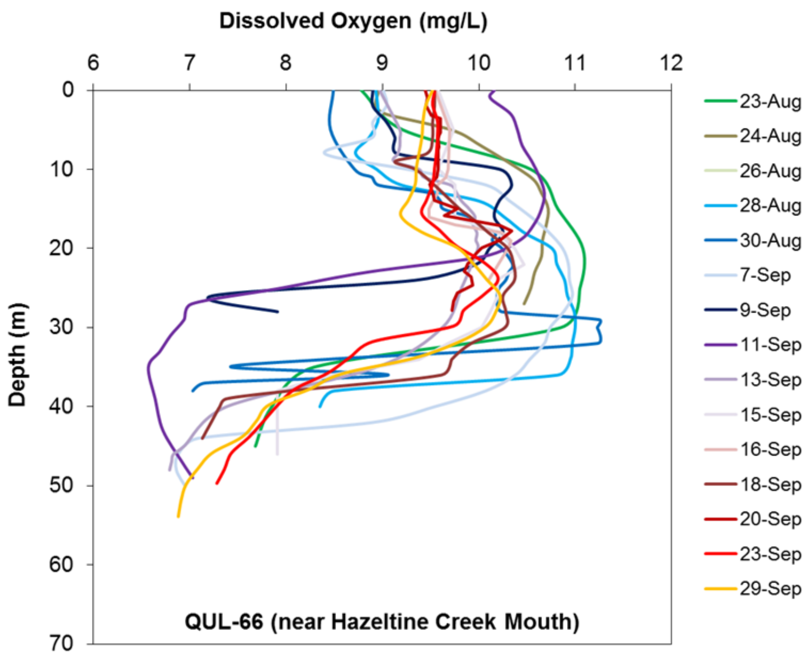


Note: The white arrow represents the approximate timing of mid-November turnover in Quesnel Lake

Figure 39: Contours of temperature measured in-situ over time at Station QUL-66 in Quesnel Lake post-event (August 2014 to December 2014). Temperature (°C) shown on right hand axis.



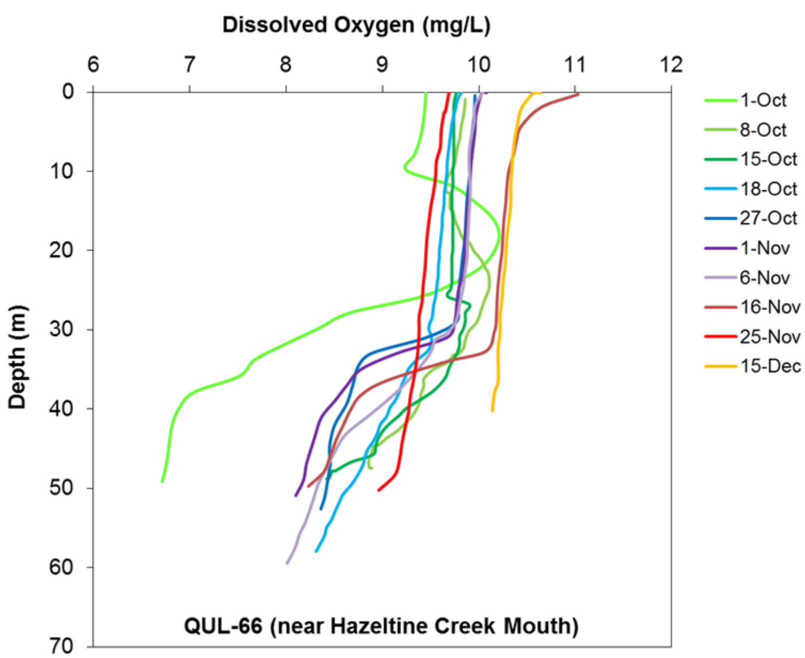


Figure 40: Depth profiles of dissolved oxygen measured in-situ over time at Station QUL-66 in Quesnel Lake post-event (August 2014 to December 2014).

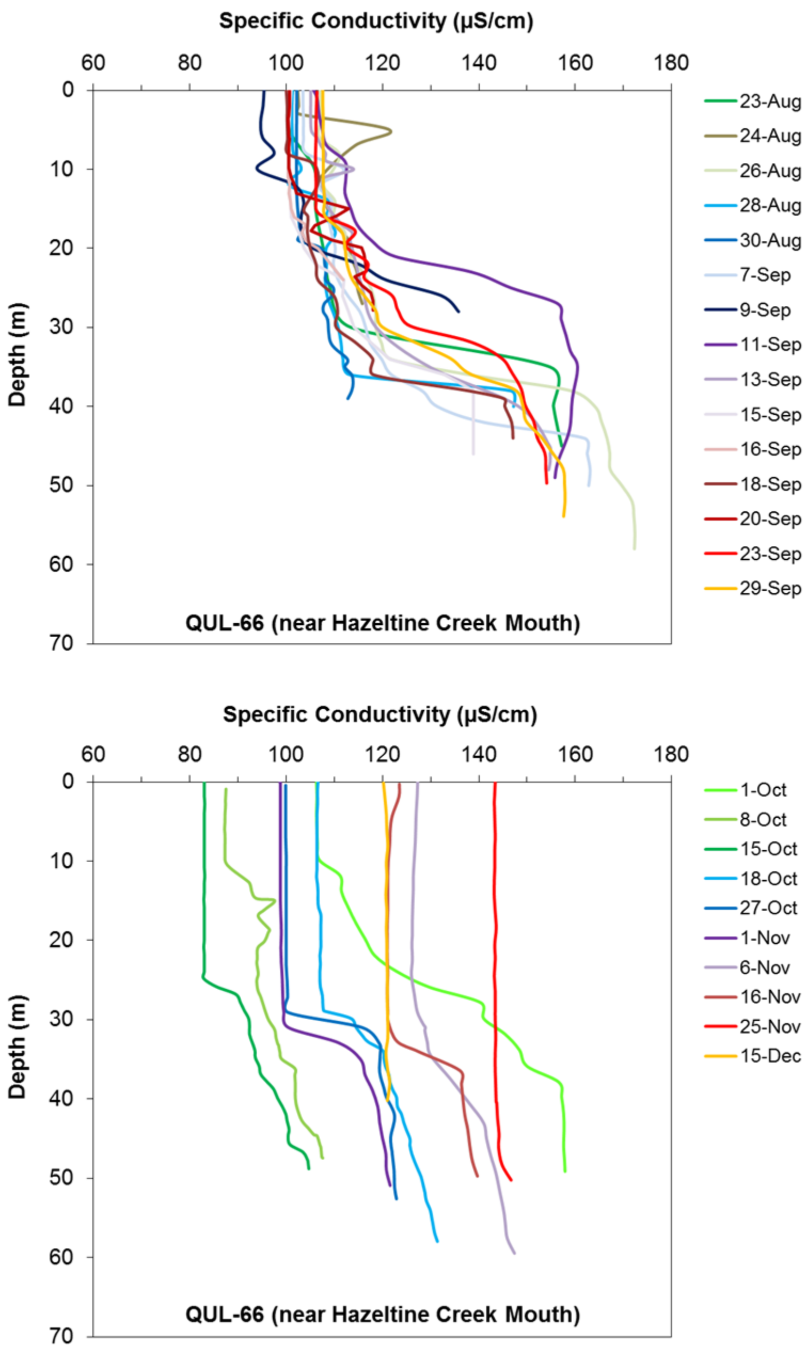

Figure 41: Depth profiles of specific conductivity measured in-situ over time at Station QUL-66 in Quesnel Lake post-event (August 2014 to December 2014).

APPENDIX F

Background on Turbidity and Total Suspended Solids

1.0 TURBIDITY AND TOTAL SUSPENDED SOLIDS

1.1 Background

Turbidity is a measure of water's cloudiness or haziness, which is caused by individual particles (e.g., total suspended or dissolved solids) that affect water clarity and how much light can be transmitted through a sample. Samples with low light transmission will have greater reported turbidity values than samples with few suspended or dissolved solids. Turbidity data are reported in nephelometric turbidity units (NTU) and measured in relation to standard samples with known turbidities (Birtwell 1999). Turbidity may be measured with relative speed and ease in the field. Field-measured values may range from 1 to 1,000 NTU (Chapman 1992).

Total suspended solids (TSS), including suspended substrate particles (e.g., clay and silt), organic matter (e.g., detritus), planktonic organisms and bacteria, contribute to turbidity (Canadian Council of Ministers of the Environment [CCME] 2002). It is the gravimetric measurement of the dry weight of suspended particulate matter (solids) per unit volume of water; it is generally accepted as the fraction of suspended matter that will not pass through a 1.5 micrometre (µm) filter (Chapman 1992). Results are expressed in terms of milligrams per litre of water (mg/L). Because measurement of TSS concentrations in water requires filtration of samples, TSS is not immediately or directly measureable under field conditions (e.g., Riley 1998). Also, TSS composition and concentrations are largely dependent on site-specific conditions. Fortunately, if site-specific sediment (e.g., particle size) and water (e.g., colour) conditions are known, turbidity data may be used as a surrogate measure of TSS (Birtwell et al. 2008).

Turbidity and TSS data may be influenced by anthropogenic activities that affect waterbodies and watercourses, as well as natural, temporal (i.e., seasonal), and spatial phenomena (Caux et al. 1997). Aquatic sediments disturbed during in-water works, such as dam and water intake construction, are potential sources of elevated turbidity and TSS. Under most natural conditions, soil erosion and weathering are the greatest contributors to turbidity. Runoff during the spring freshet may carry seasonally high concentrations of suspended soil particles; runoff from heavy rainfall may also result in short-duration spikes in turbidity and TSS concentrations within affected waterbodies and watercourses (Chapman 1992). High-flow events may also scour and re-suspend substrates on the streambed, thereby increasing TSS and turbidity (Birtwell 1999). Biological activity, such as the proliferation of planktonic organisms during warm summer months, may also have a seasonal effect on turbidity and TSS measurements (Chapman 1992).

1.2 Implications for Drinking Water

Turbidity may affect drinking water quality by reducing the aesthetic appeal of water and/or reducing the effectiveness of water treatment methods. For example, ultraviolet radiation, which must be transmitted through the water to effectively eliminate pathogens, may be less effective in turbid drinking water (Marquis 2005). Additionally, suspended particles may serve as vectors for adhered pathogens or promote the growth of micro-organisms (Caux et al. 1997; Marquis 2005; Mattioli et al. 2013).

1.3 Implications for Aquatic Life

As stated in Section 1.1, turbidity may be used as a surrogate measure of TSS. Turbidity and suspended solids affect light penetration, which, in turn, has implications for photosynthetic organisms at the base of aquatic food webs (Birtwell et al. 2008). Suspended sediments may also settle out of the water column and fill the interstitial spaces within aquatic substrate, thereby reducing the quantity and quality of cover and habitat available to macroinvertebrates, fish eggs, and fish fry.

Elevated concentrations of suspended solids may affect fish health and survival by abrading or clogging the gills, altering behaviour (e.g., migration), and reducing the foraging efficiency of sight-feeding species (CCME 2002; Newcombe and Jensen 1996; Robertson et al. 2006). Because exposure duration may influence how an organism responds to elevated TSS concentrations, it is possible that fish and other aquatic organisms may withstand high concentrations of TSS for short periods and low levels of TSS for longer periods (e.g., 30 days; Section 1.4) (Birtwell 1999; Newcombe and Jensen 1996). However, TSS concentrations less than 25 mg/L are generally considered safe for aquatic life and lethal effects in fish generally occur only when the TSS concentrations are very high (European Inland Fisheries Advisory Commission 1964). For example, studies that investigated lethal effects of TSS on salmonids showed that it took 31,000 mg/L and 17,600 mg/L to kill 50% of juvenile chinook and sockeye salmon test subjects respectively, over a 96h test period (Servizi and Gordon 1990; Servizi and Martens 1987).These concentrations are not commonly encountered in waterbodies except under extreme circumstances.

1.4 Guidelines

Provincial ambient water quality guidelines for turbidity exist in British Columbia (BC) (Table 1). These guidelines are intended to promote the safety of potable water and protect aquatic life from deleterious health effects (e.g., reduced growth, disease) and habitat alterations (e.g., covering of spawning substrates) (see Sections 1.2 and 1.3, above; Birtwell 1999; Caux et al. 1997). Consequently, the BC ambient water quality guidelines include criteria specifically targeted at the protection of drinking water, aquatic life, recreation and aesthetics, wildlife irrigation, livestock watering, and industrial water supplies (Caux et al. 1997). Provincial turbidity guidelines for the protection of aquatic life are in agreement with guidelines developed by the CCME for clear flow and high flow/turbid conditions (CCME 2002).

Turbidity criteria are based on changes, reported in NTU, that occur relative to background conditions within the receiving environment. It is therefore necessary to understand the naturally occurring range of turbidity levels within the waterbody or watercourse of interest, as well as temporal (e.g., seasonal) trends that may exist. Clear and high flow/turbid conditions referred to in the guidelines (Table 1) are intended to describe different portions of the annual hydrograph (Caux et al. 1997).

In addition to the guidelines for turbidity, BC MoE has ambient water quality guidelines for suspended sediments (Table 2). The guidelines refer to the fraction of a water sample that does not pass through a 1.5 µm glass fibre filter, which includes suspended sediment particles, detritus, and other biotic or abiotic solids (Caux et al. 1997). Like the guidelines for turbidity, the TSS guidelines are intended to protect aquatic life from deleterious health effects and habitat alteration (see Sections 1.2 and 1.3, above; Birtwell 1999; Caux et al. 1997). Specific guidelines therefore exist for aquatic life, wildlife irrigation, livestock watering, and industrial water supplies (Caux et al. 1997).

Table 1: BC MoE Ambient Water Quality Guidelines for Turbidity

Water Use	Background Conditions	Turbidity Guideline, Relative to Background Conditions
Raw drinking water with treatment to remove particulates	≤50 NTU	maximum 5 NTU change
	>50 NTU	maximum 10% change
Raw drinking water without treatment to remove particulates	≤5 NTU	maximum 1 NTU change
	>5 NTU	maximum 5 NTU change
Aquatic life (freshwater, marine and estuarine)[a]	clear flow (<8 NTU)	maximum 8 NTU change over 24-h duration maximum 2 NTU change over 30-d duration
	high flow/turbid conditions (8 to 50 NTU)	maximum 5 NTU change
	high flow/turbid conditions (>50 NTU)	maximum 10% change
Recreation and aesthetics	≤50 NTU	maximum 5 NTU change
	>50 NTU	maximum 10% change
Wildlife irrigation	≤50 NTU	maximum 10 NTU change
	>50 NTU	maximum 20% change
Livestock watering	≤50 NTU	maximum 5 NTU change
	>50 NTU	maximum 10% change
Industrial water supplies	≤50 NTU	maximum 10 NTU change
	>50 NTU	maximum 20% change
	No turbidity increases that will adversely affect established industrial water supplies	

Notes:

[a] The BC MoE guidelines for the protection of aquatic life are in agreement with the Canadian Council of Ministers of the Environment (CCME) guidelines (CCME 2002).

Notes: BC MoE = British Columbia Ministry of Environment; ≤ = less than or equal to; NTU = nephelometric turbidity units; > = greater than; % = percent; < = less than; h = hour; d = day.

Table 2: BC MoE Ambient Water Quality Guidelines for Total Suspended Solids

Water Use	Background Conditions	TSS Guideline, Relative to Background Conditions
Raw drinking water with treatment to remove particulates	no guidelines	
Raw drinking water without treatment to remove particulates	no guidelines	
Aquatic life (freshwater, marine and estuarine)	clear flow (<25 mg/L)	maximum 25 mg/L change over a 24-h exposure average maximum 5 mg/L change over a 30-d exposure
	high flow/TSS conditions (25 to 100 mg/L)	maximum 10 mg/L change
	high flow/TSS conditions (> 100 mg/L)	maximum 10% change
Recreation and aesthetics	no guideline	
Wildlife irrigation	≤100 mg/L	maximum 20 mg/L change
	>100 NTU	maximum 20% change
Livestock watering	≤100 mg/L	maximum 10 mg/L change
	>100 mg/L	maximum 10% change
Industrial water supplies	≤100 mg/L	maximum 20 mg/L change
	>100 mg/L	maximum 20% change
	No turbidity increases that will adversely affect established industrial water supplies	

Notes:
BC MoE = British Columbia Ministry of Environment; TSS = total suspended solids; < = less than; mg/L = milligrams per litre; h = hour; d = day; > = greater than; % = percent; ≤ = less than or equal to.
Source: Caux et al. 1997.

The BC MoE ambient water quality guidelines for clear flow conditions are in agreement with CCME clear flow guidelines (CCME 2002). However, the provincial and federal guidelines differ where background concentration are greater than 25 mg/L. Federal guidelines indicate that when background TSS levels are between 25 and 250 mg/L, the maximum allowable increase is equal to 25 mg/L (CCME 2002). When background concentrations are greater than 250 mg/L TSS, a maximum 10% increase relative to background conditions is considered acceptable.

The guidelines in Tables 1 and 2 are generic and intended to be applicable province wide. Erosion control measures and settling ponds are considered practical solutions for managing and reducing turbidity and TSS concentrations in run-off and process waters, prior to their introduction to receiving aquatic environments (Birtwell et al. 2008).

Copper Speciation Technical Memorandum

TECHNICAL MEMORANDUM

DATE June 5, 2015 **PROJECT No.** 1477134/10000/2000

TO Jordana Van Geest, Elaine Irving and Lee Nikl
Golder Associates Ltd.

FROM Kristin Salzsauler and Michael Herrell **EMAIL** mherrell@golder.com

MOUNT POLLEY MINE: GEOCHEMICAL SPECIATION MODELLING OF SURFACE WATER QUALITY MONITORING DATA

1.0 INTRODUCTION

On August 4, 2014, a foundation failure of the Tailings Storage Facility (TSF) dyke and subsequent debris flow occurred at Imperial Metal's Mount Polley Mine causing water and tailings to be released to the downstream environment. The TSF breach resulted in discharge of approximately 10 million cubic meters (m^3) of water and tailings into Polley Lake, Hazeltine Creek and into Quesnel Lake. Surface water quality monitoring results from select monitoring locations within Quesnel Lake and Quesnel River underwent geochemical speciation modelling to evaluate aqueous copper speciation. The geochemical speciation modelling was completed as part of the Surface Water Quality Impact Assessment Technical Report (a component of the Post-Event Environmental Impact Assessment Report [PEEIAR]).

This technical memorandum presents the data and assumptions used to conduct the geochemical speciation modelling, the model approach, and a factual summary of the model results.

2.0 APPROACH

2.1 Input Water Quality

The results of water quality sample analysis from four (4) locations in Quesnel Lake and one (1) location in the Quesnel River were selected for geochemical speciation modelling. The stations were selected to provide spatial representation across the West Basin of Quesnel Lake, the area that received much of the materials released by the breach. Table 1 summarizes the location of each monitoring station, including the number of near surface samples (i.e., water samples collected from less than 20 meters [m] below the water surface), and the number of samples collected from depth (i.e., greater than 20 meters below lake surface) at each location.

Table 1: Post-Event Routine Water Quality Monitoring Stations (August 2014 to February 2015) Selected for Geochemical Speciation Modelling

Area	Station Name	Number of Surface Samples[(a)]	Number of Samples at Depth	Sample Depth Range (meters)	Number of Profiles	Date Range (mm/dd/yyyy)
Quesnel River	QUR-1	293	N/A	N/A	N/A	08/06/2014 - 02/23/2015
Quesnel Lake - near Hazeltine Creek mouth	QUL-66	25	51	10 - 85	28	08/24/2014 - 01/15/2015
Quesnel Lake - near Hazeltine Creek mouth	QUL-66a	14	25	40 - 105	13	09/25/2014 - 12/16/2014
Quesnel Lake east towards Cariboo Island	QUL-2	22	32	8 - 50	21	08/06/2014 - 11/18/2014
Quesnel Lake – northwest towards Quesnel River	QUL-21	30	41	6 - 47	22	08/08/2014 - 11/06/2014

Notes:
(a) Samples collected from a depth of less than 20 meters.
N/A – not applicable

As described in the Surface Water Quality Impact Assessment Technical Report, Quesnel Lake is a large, deep fjord lake; the lake is comprised of East, West and North Arms. The West Basin is a shallower portion of the West Arm that is separated from the rest of the lake by a shallow sill near Cariboo Island, west towards Quesnel River. The West Basin has vertical mixing that is typical of temperate lakes, with thermal stratification for most of the year interrupted by brief turnover periods in the spring and the fall when vertical density gradients are lowest. Quesnel Lake outflows into the Quesnel River, which is a major tributary of the Fraser River located in the Cariboo District of central British Columbia. From its outflow at Quesnel Lake, the Quesnel River flows approximately 100 kilometres (km) to the northwest, descending 2,500 m to its confluence with the Fraser River at the town of Quesnel.

Data from each monitoring location used in the development of inputs to the geochemical speciation model included:

- Field measurements collected using a YSI EXO sondes, including depth, temperature, specific conductance, pH, dissolved oxygen, oxidation-reduction potential (ORP), turbidity, and total dissolved solids (TDS).
- Results of laboratory sample analysis, including:
  - Dissolved and total metals (i.e., aluminum, antimony, arsenic, barium, beryllium, bismuth, boron, cadmium, calcium, chromium, cobalt, copper, iron, lead, lithium, magnesium, manganese, molybdenum, nickel, selenium, silicon, sodium, strontium, thallium, tin, titanium, uranium, vanadium and zinc);
  - Anions and nutrients (i.e., ammonia, chloride, nitrate, nitrite, total nitrogen, orthophosphate, total phosphorous, total dissolved phosphorous and sulphate);
  - Total mercury;
  - Alkalinity; and
  - Dissolved organic carbon.

Water samples were collected and submitted by Mount Polley Mining Corporation for laboratory analysis at regular intervals over the monitoring periods outlined in Table 1. Field measurements of pH, temperature, and specific conductance taken at the time of sample collection were used for input to the speciation model. ORP was assigned to each sample based on a review of ORP profiles measured over time (monitoring stations QUR-1, QUL-2, QUL-21, QUL-66 and QUL-66a) and with depth (monitoring stations QUL-2, QUL-21, QUL-66 and QUL-66a), as described in Section 2.3.

2.2 Geochemical Modelling

Geochemical speciation was assessed with the equilibrium speciation and mass-transfer code PHREEQC Version 3.0.6-7757 (Parkhurst and Appelo, 1999). PHREEQC predicts the concentration of metal species based on metal concentrations and water quality parameters that are known to affect speciation, such as pH, redox potential and the concentrations of other constituents in solution that may form aqueous complexes with the parameter in question.

2.3 Sensitivity Analysis

Redox potential is a key parameter controlling copper speciation. Field measured ORP ranged from approximately 50 to 300 mV at all stations and depths over time. Therefore, the range in measured ORP values was represented by assigning a lower bound (i.e., 50 to 150) and upper bound (i.e., 300 mV) value to each sample, in order to evaluate speciation sensitivity to redox potential. The field measured ORP was converted to Eh (mV) by adding 200 mV to each field measurement, as per the YSI Sonde specificiations. Eh was then converted to pe according to the Nernst equation, which accounts for the measured field Eh and field temperature.

3.0 RESULTS

Appendix A presents the detailed results of speciation modelling for water quality monitoring locations QUL-1, QUR-2, QUR-21, QUR-66 and QUR-66a. The main species at each monitoring location are presented in Table 2. The results in Table 2 are presented as the average proportion of each species over the monitoring period at each location.

Table 2: Average Proportion of Copper Species in Samples Collected from Select Monitoring Stations August 2014 to February 2015

Monitoring Location		QUR-1		QUL-66		QUL-66a		QUL-2		QUL-21	
Eh		500 mV	300 mV	500 mV	350 mV	500 mV	250 mV	500 mV	300 mV	500 mV	300 mV

* Individual species present in quantities less than 0.1%.

As presented in detail in Appendix A, redox potential had a minimal effect on copper speciation within the range of modelled (i.e., measured) Eh values. Copper speciation was similar for both the high and low Eh model scenarios. The main controls on copper speciation were pH and the relative concentrations of the complexing species.

Figures 1 through 5 present the relative distribution of each copper species over time in comparison to the dissolved copper concentration measured in each sample for the high Eh model scenario. Figures 2 to 5 present the copper speciation results at depth in Quesnel Lake. Speciation was also completed on samples collected at surface (i.e., at a depth <20m); however, only the speciation results from samples collected at greater than 20 m depth were included on the charts, since these represent the highest observed copper concentrations. Overall, Cu^{2+} species dominated in water quality samples collected from all stations. There was very little variation in copper speciation over time. The main copper species were $CuCO_3$ (on average >80% of total) with minor Cu^{2+}, $CuOH^+$, and $Cu(OH)_2$.

Figure 6 is an example copper speciation diagram. This figure illustrates that under cicum-neutral pH conditions (i.e., pH values of 6 to 8), divalent copper species dominate at Eh values above approximately 185 mV. In most natural waters, Eh cannot be measured unambiguously (Appelo and Postma, 1994). Difficulties in the measurement of redox potentials are attributed to a number of factors including the presence of multiple redox species, a lack of equilibrium between redox species and analytical difficulties in direct measurements of redox potential. For this reason, the redox condition of waters determined from ORP measurements is often compared against the absence or presence of redox species. The presence of dissolved oxygen (~6 to 12 mg/L) and absence of dissolved iron (i.e., typically <0.03 mg/L) are indicative of oxidizing conditions in surface water which is consistent with the ORP measurements.

4.0 SUMMARY

Geochemical speciation modelling was completed as part of the Surface Water Quality Impact Assessment Technical Report (a component of the PEEIAR). The objective of geochemical speciation modelling was to evaluate aqueous copper speciation. The results of water quality sample analysis from four (4) locations in Quesnel Lake (QUL-66, QUL-66a, QUL-21 and QUL-2) and one (1) location in the Quesnel River (QUR-1) were selected for geochemical speciation modelling (Table 1).

Geochemical model results indicate that the main copper species in water quality samples collected from Quesnel Lake and the Quesnel River were $CuCO_3$ with minor Cu^{2+}, $CuOH^+$, and $Cu(OH)_2$; Cu^{2+} species dominated in water quality samples collected from all stations. Copper speciation was similar in high and low Eh model scenarios. The main controls on copper speciation were pH and the relative concentrations of the complexing species.

POST-EVENT IMPACT ASSESSMENT REPORT: Terrestrial Wildlife and Vegetation

Prepared for: Mount Polley Mining Corporation

SNC-LAVALIN INC.

May 28, 2015

FINAL REPORT / V-01
621717

EXECUTIVE SUMMARY

The scope of the terrestrial wildlife and vegetation assessment included characterization of the effects of the Mount Polley tailings dam failure on terrestrial wildlife and vegetation species and plant communities that are classified federally or provincially as at risk, are listed as regionally important by the Cariboo-Chilcotin Land and Resource Management Plan, or are subjects of provincial legal or policy directions or harvest management. Sensitive habitats that are subjects of provincial or federal legal or policy directions - defined as old-growth forest and wetlands – affected by the tailings dam failure were quantified. The study area was delineated by terrain specialists from aerial imagery and from field surveys by terrain and soils specialists. The terrestrial study area includes all terrestrial areas that were subjected to tailings or debris deposition or to active erosion resulting from the tailings dam failure. It does not include the Hazeltine Creek channel area (6 ha) as impacts on that area will be reported as part of the Fish and Fish Habitat Impact Assessment.

Assessment of the effects on terrestrial wildlife and vegetation was difficult due to the lack of baseline data on the habitats and species that were present in the study area. Terrestrial Ecosystem Mapping (TEM) and data from post-event field visits to the study area were used as the basis for the assessment. The tailings dam failure affected 234.3 ha of terrestrial habitat (the study area), which included 200.3 ha designated by the province as Old Growth Management Area (OGMA) and 4.9 ha of wetland habitat. Site series associated with three different at-risk ecological communities, as defined by the province, were mapped within the study area: the Red-listed Scrub birch-Sedges-Peat moss (4.9 ha), the Blue-listed Western Redcedar / Oak Fern / Electrified Cat's-Tail Moss (53.4 ha), and the Blue-listed Western Redcedar / Falsebox (29.5 ha).

The potential impacts of the tailings dam failure on specific rare plant occurrences cannot be quantified. There are no occurrence records for rare plants within the study area as no rare plant surveys are known to have been performed there before the tailings dam failure. Any rare plant occurrences that survived after the initial dam failure would face greatly altered habitat conditions that could reduce their viability.

The flood of tailings and debris from the tailings dam failure would likely have resulted in some degree of wildlife mortality but the extent of that mortality cannot be quantified. Based on natural history characteristics, mortality effects are inferred as probable for the provincially Blue-listed western toad (*Anaxyrus boreas*) and are inferred as possible for two SARA-listed endangered bat species, little brown myotis (*Myotis lucifugus*) and northern myotis (*Myotis septentrionalis*). Mortality effects are inferred as possible for any beavers (*Castor canadensis*) that may have occupied lodges on Hazeltine Creek. One wetland identified as moderate suitability moose winter habitat was removed. The tailings dam failure also resulted in loss of summer habitat for mule deer (*Odocoileus hemionus*), breeding habitat for fishers (*Pekania pennanti*), breeding habitat for

western toad, living habitat for beavers, and roosting habitat for bats. No provincially-designated Wildlife Habitat Areas or designated winter ranges for mule deer or caribou (*Rangifer tarandus*) were affected. The Mount Polley Mine is located within an area where grizzly bears (*Ursus arctos*) are considered extirpated so the tailings dam failure did not result in impacts on that species. The habitat effects of the tailings dam failure are not likely to result in effects to regional wildlife populations based on the size of the study area and the amount of alternative habitat available. The assessment of potential long-term effects on wildlife, plants and ecosystems will be carried out in a future Ecological Risk Assessment (ERA).

GLOSSARY

Anthropogenic	Created by people.
Bioterrain	A classification system that combines recognizable permanent terrain and landscape features with recognizable biological and inferred soil drainage characteristics.
Blue list	Refers to species and ecological communities with a conservation status of Special Concern in British Columbia.
Coniferous	Refers to trees that have needles or scales instead of leaves.
Deciduous	Refers to trees that have broad leaves that are shed in the fall.
Duff	The litter layer of fallen leaves, small twigs, needles and other plant debris on the surface of the soil.
Edaphic	Characteristics relating to soils
Emergent	Refers to a plant that is rooted in a waterbody and grows out of the water (e.g., cattail).
Ephemeral	Refers to a habitat feature that is not always present (e.g., an ephemeral waterbody only contains water at certain times of the year).
Extirpated	Refers to a species that is no longer present in a particular area but still exists elsewhere (i.e., is not extinct).
Gastropod	A class of molluscs that includes slugs and snails.
Generalist	Refers to an organism that uses a variety of foods or habitats.
Mustelid	A member of the weasel family.
Non-vascular plants	Mosses, liverworts and lichens.
Raptor	Species of predatory birds that have a hooked beak and feet with talons.
Red list	Refers to species and ecological communities with a conservation status of Extirpated, Endangered, or Threatened in British Columbia.
Riparian	Refers to the terrestrial ecosystems adjacent to a water body that are influenced by the presence of the water body.
Rut	The mating season of ungulates.
Seral	Refers to the stages of ecological succession.

GLOSSARY (Cont'd)

Snag	A standing dead tree.
Terrestrial Ecosystem Mapping	A provincial standard system of mapping that uses bioterrain characteristics combined with vegetation cover to delineate terrestrial ecosystems.
Ungulate	A hoofed mammal; in this report includes deer, moose and caribou.
Vascular plants	Trees, shrubs, grasses, herbs, and forbs.
Veteran	Refers to a large old tree that is older and larger than the surrounding trees and has survived previous disturbances.

1 INTRODUCTION

Early on August 4, 2014, a tailings dam failure occurred at Mount Polley Mine (MPM) causing water and tailings to be released. SNC-Lavalin was retained to prepare an assessment of the impacts on terrestrial ecosystems, vegetation and wildlife. Those impacts include an assessment of the immediate physical impacts of the tailings dam failure and potential long-term effects on habitats and food webs. The scope and objectives of this report are defined and described below.

1.1 Scope and Objectives

The objectives of this assessment are to:

- Characterize the ecosystems, wildlife and plant species known present or likely present in the study area before the tailings dam failure. The characterization will be focused on ecosystems and taxa that are at-risk or of regional importance.
- Describe the extent and nature of the immediate impacts of the tailings dam failure on the ecosystems, wildlife and plant species, focused on the ecosystems and taxa identified through the first objective. The effects of the ongoing remediation work are not considered in this assessment.

The long-term effects of contamination of water, soil and vegetation, will be assessed in a future Ecological Risk Assessment (ERA).

<u>Spatial and Temporal Boundaries</u>

The MPM is located within the Quesnel Highland Ecosection, which is part of the Columbia Highlands Ecoregion. The Quesnel Highland Ecosection is a highland area, situated between plateaus on the west and higher mountain ranges to the east (Demarchi 2011). Moist air flowing east from the Pacific Ocean generates considerable precipitation as either rain or snow, and cold Arctic air in the winter months can result in sub-zero temperatures for extended periods. Wet Interior Cedar – Hemlock (ICH) forests are prevalent in the valleys and lower slopes, while cold-tolerant Engelmann Spruce – Subalpine Fir (ESSF) forests dominate the upper slopes and lower mountain summits (Demarchi 2011).

Climate, as well as geological and anthropogenic processes (e.g., historic and current mining activities, forestry, and settlements) have shaped the current ecosystems and associated seral stages found in the general area. The Horsefly Sustainable Resource Management Plan (HSRMP) was led by the provincial government as part of the implementation of the Cariboo Chilcotin Land Use Plan to manage multiple interests within the general area. The plan provides detailed area-based resource targets and strategies for a number of uses, such as timber harvesting, mining, fishing, biodiversity conservation, and tourism (HSRMP 2005).

1.1.1 Study Area

The terrestrial study area (the 'study area') is 234.3 ha in total (Figure 1-1). The study area was delineated by terrain specialists from aerial imagery and from field surveys by terrain and soils specialists (see Soil Quality Impact Assessment). The terrestrial study area includes all terrestrial areas that were subjected to tailings or debris deposition or to active erosion resulting from the tailings dam failure. It does not include the Hazeltine Creek channel area (6 ha) as impacts on that area will be reported as part of the Fish and Fish Habitat Impact Assessment.

The study area is located within the ICH biogeoclimatic zone, and includes two biogeoclimatic subzone variants: the Horsefly moist cool ICH variant (ICHmk3) and the Quesnel wet cool ICH variant (ICHwk2). Brief descriptions are provided below from Steen and Coupé (1997).

The ICHmk3 occurs on gently rolling terrain along the eastern flank of the Fraser Plateau and adjacent portions of the Quesnel Highland from Quesnel Lake in the north to McNeil Lake in the south, at elevations between 780 m and 1250 m (Steen and Coupé 1997). The ICHmk3 is characterized by drier climates and absence of western hemlock (*Tsuga heterophylla*). Dominant tree species include western redcedar (*Thuja plicata*), hybrid white spruce (*Picea glauca x engelmannii*) and Douglas-fir (*Pseudotsuga menziesii*). The understory typically includes falsebox (*Paxistima myrsinites*), and moss species such as red-stemmed feathermoss (*Pleurozium schreberi*) and knight's plume (*Ptilium crista-castrensis*).

The ICHwk2 occurs in moist valleys of the Quesnel Highland and Cariboo Mountains south of Mitchell Lake, and is centred on Quesnel Lake. The ICHwk2 lies east and north of the ICHmk3 in wetter climates at similar elevations (725 m to 1250 m). Dominant tree species in this variant are western hemlock and western redcedar, as well as hybrid white spruce. Understory species include oval-leaved blueberry (*Vaccinium ovalifolium*) and bunchberry (*Cornus canadensis*), with step moss (*Hylocomium splendens*) and pipecleaner moss (*Rhytidiopsis robusta*) common in the moss layer.

1.1.2 Acknowledgements

The terrestrial wildlife and vegetation assessment was prepared by Lorraine Andrusiak, M.Sc. R.P.Bio., supervised by Shawn Hilton, B.Sc., R.P.Bio. The assessment of effects on rare plants was provided by Randy Krichbaum, M.Sc., R.P.Bio. (Eagle Cap Consulting). Andrea Paetow, R.P.Bio. contributed to fieldwork and initial drafts. Map preparation and spatial analyses were completed by Lara Hoshizaki, M.Sc., and Cameron Wallace, B.Sc. The Project Sponsor was Gordon Johnson, M.Sc., P.Eng.

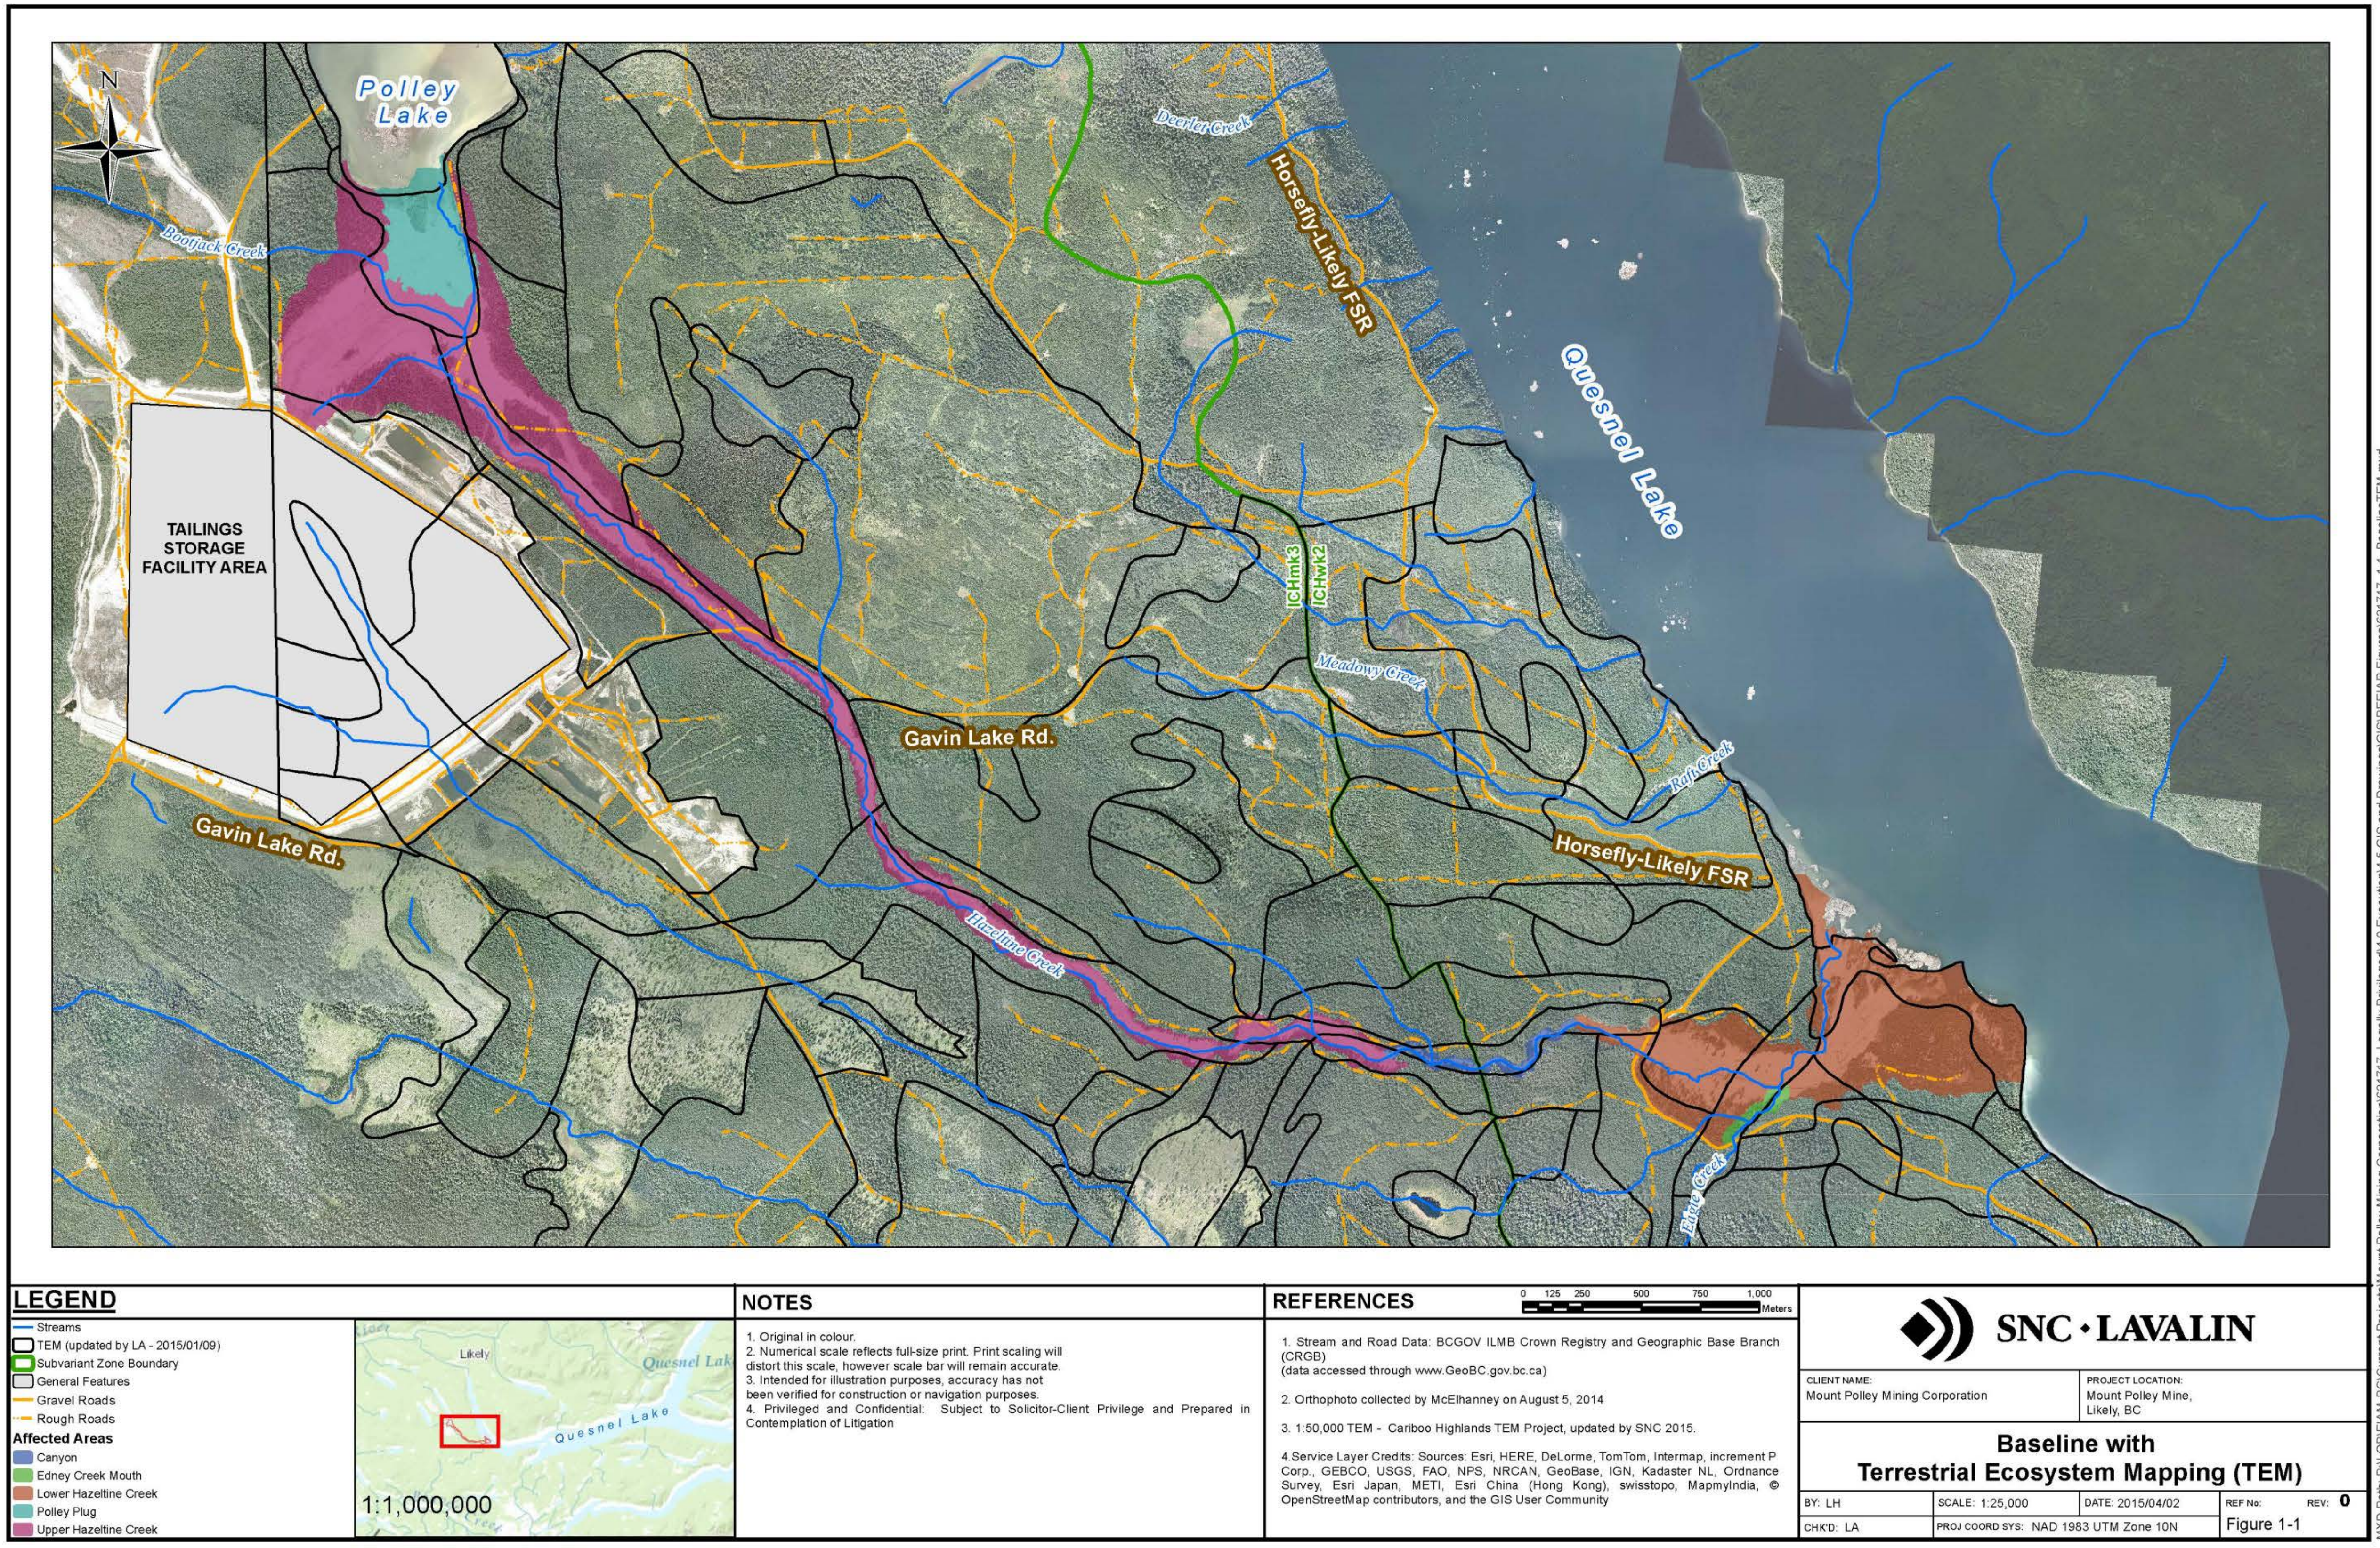

Figure 1-1: Study area

2 METHODS

Provincial wildlife and vegetation databases available through Data BC (http://maps.gov.bc.ca/ess/sv/imapbc/) were queried to locate any relevant pre-existing data for the study area. No records of terrestrial wildlife or vegetation surveys near Polley Lake or Hazeltine Creek could be located. The baseline for terrestrial wildlife and vegetation has been characterized based on:

- Field data obtained from field assessments and sampling activities occurring after the tailings dam failure in unaffected habitats just outside the borders of the study area;
- Map data from a Terrestrial Ecosystem Mapping project (Geowest 2001);
- Spatial boundaries of provincially managed habitat areas delineated within the study area, including Old Growth Management Areas (OGMAs) and high-value moose (Alces americanus) wetlands, obtained from the Province;
- Regional species checklists and known species occurrences;
- Published and unpublished literature on plants, wildlife, and wildlife use of habitat types found in the study area; and
- Professional judgement.

Focal species were selected based on methodology described in BC Ministry of Environment (2014), which includes consideration of species for which there are government legal or policy objectives or harvest management, and those that have federal or provincial status as species at risk. Information on species distribution and provincial and federal status was obtained from the BC Conservation Data Centre's website (BC Conservation Data Centre 2014a), and from Province of BC (2014). The immediate effects of the tailings dam failure on ecosystems were quantified by overlaying the extent of the study area with the ecosystem mapping and summarizing the ecosystems within the overlapping area.

2.1 Vegetation

2.1.1 Terrestrial Ecosystem Mapping

Terrestrial Ecosystem Mapping (TEM) can be used to provide quantitative information about the physical and vegetation characteristics of the study area and the impacts on habitat that occurred due to the tailings dam failure. TEM is a provincial standard method of ecosystem mapping that includes both bioterrain and ecosystem attributes (RIC 1998). Site series are described and defined by the BC Ministry of Forests as sites within a biogeoclimatic subzone or variant that are capable of producing the same mature or climax vegetation. Mapped ecosystems are typically drawn from a combination of forested site series defined in the relevant regional site series guidebook produced by the BC Ministry of Forests (e.g., Steen and Coupé 1994), wetland units defined in MacKenzie and Moran (2004), and anthropogenic/nonvegetated units defined by the BC Ministry of Environment (2008). Additional map units may be defined on a project-specific basis. The age/seral stage of a mapped ecosystem is indicated by its structural stage (Table 2-1).

Table 2-1: Structural Stage Definitions (RIC 1998)

Structural Stage	Definition
3a	**Low Shrub:** Shrubs less than 2 m tall, time since disturbance less than 20 years for normal forest succession
3b	**Tall Shrub**: shrubs less than 10 metres tall, less than 40 years old in normal forest succession
4	**Pole /Sapling**: trees greater than 10 metres tall, usually less than 40 years old
5	**Young Forest**: trees typically 40 to 80 years old
6	**Mature Forest**: trees 80 to 250 years old
7	**Old Forest**: greater than 250 years old

TEM polygons delineate distinct areas on the landscape composed of up to three different ecosystem unit/structural stage combinations. TEM was completed in 2001 at 1:50,000 scale for the East Cariboo Highlands area east of Likely, and that mapping covers the eastern portion of the Mount Polley tailings facility, the southeast portion of Polley Lake, Hazeltine Creek and Quesnel Lake (Geowest 2001). Predictive Ecosystem Mapping (PEM) at 1:20,000 (2008) was also available for the Quesnel Lake area (Moon 2008). As PEM is generated from computer algorithms, while TEM polygons are characterized individually by an ecologist from aerial photographs, the TEM was chosen for use in this assessment.

Ecosystem field data were collected during sampling after the tailings dam failure occurred, in order to check the accuracy of the TEM. Plots were generally done in undisturbed vegetation just beyond the boundaries of the deposition zone. The field results were compared to the labels of the TEM polygons in which the plots were located. The map polygons within 1 km of the study area were edited to reflect structural stage changes from recent harvesting, forest growth and mine development, and some ecosystem editing was done based on the data from the field plots. Vegetation Resources Inventory (VRI) mapping was used to confirm the structural stage updates.

The study area was delineated by terrain specialists from aerial imagery and from field surveys by terrain and soils specialists (see Soil Quality Impact Assessment). The study area was overlain with the updated TEM and divided into sub-areas – remediation units - for the purpose of assessment. The ecosystems within the study area were quantified by multiplying the area of the portion of each TEM polygon within the study area by the contribution of each ecosystem decile, and summarized by affected area.

2.1.2 Rare Ecological Communities

An ecological community can be defined as a particular suite of living organisms (plants, animals, fungi, bacteria, etc.) that co-occur on particular associated environmental site characteristics including soil, landform, nutrient, and moisture regimes. At-risk ecological communities are defined and ranked by the BC Conservation Data Centre (CDC) and placed on the provincial Red or Blue list according to a number of criteria such as the degree of threat, trend in area of occupancy, number of protected and managed occurrences, intrinsic vulnerability, specificity of habitat requirements, and other considerations (BC Conservation Data Centre 2004). Forest or wetland plant communities listed by the CDC are usually – but not always – associated with one or more forest or wetland site series. The association indicates that the site series has the potential to support the community in question but the community will not necessarily be present at each occurrence of the site series. Information on at-risk plant communities potentially present within the subzone variants of the study area was obtained from the BC Conservation Data Centre (2014a).

2.1.3 Old-growth Forest and Old-growth Management Areas

Old forests provide valuable habitat for plant and animal species that prefer large-diameter trees, multi-layered stands, high densities of snags and other characteristics that require many years to develop (Richardson 2005). Old forest habitat takes a long time to regenerate once it is lost. For the purposes of this report, old-growth forest is defined as forest in structural stage 7.

The identification of Old-growth Management Areas (OGMAs) is a key component in biodiversity planning in forested areas of the province. OGMAs are areas reserved from timber harvest and are intended to help maintain the environmental and non-timber values of old forest (Biodiversity Conservation Strategy Committee 2011). The province has been divided into Landscape Units for the purposes of provincial biodiversity conservation planning, and the amount of forest to be reserved as OGMAs (OGMA 'target') is dependent on the biodiversity emphasis assigned to each Landscape Unit and on the biogeoclimatic subzones present. OGMA management in the Cariboo-Chilcotin incorporates three types of OGMAs (Biodiversity Conservation Strategy Committee 2011):

- Permanent (static) OGMAS with fixed boundaries. These OGMAs may not always be old forest as they are subject to natural disturbance, but they will remain designated as OGMAs.

- Rotating OGMAs that will be harvested and replaced, which have been established in areas with a higher frequency of large natural disturbance. Eventually, these will be replaced with permanent static OGMAs.
- Transition OGMAs are temporary and will be in place until the other contributing no-harvest areas in a landscape unit develop into old forest, or until twenty years after the Land Use Order was declared (June 2010).

The study area is located within the Polley Landscape Unit (LU), which is 44,193 ha in size and has been assigned a 'High' Biodiversity Emphasis. Permanent OGMAs have been identified within this LU along Hazeltine Creek between Polley Lake and Quesnel Lake. During OGMA establishment in 2013 it was noted that there was insufficient old forest available within the Polley LU to make up the full target for old forest (Cariboo-Chilcotin Region Higher Level Plan 2013), so the identified OGMAs consist of mature as well as old forest. The mature forest will eventually develop the structural characteristics of old growth. The spatial boundaries of the OGMAs were obtained from the provincial government and overlain with the study area to quantify the amount of OGMA affected.

For the purposes of this assessment, old forest was quantified by overlaying the revised TEM polygons with the boundaries of the study area. The area of forest mapped as structural stage 7 was summarized by remediation area.

2.1.4 Wetlands

Wetlands cover about 6% of the province and perform essential hydrological and ecological functions (BC Ministry of Forests 2000). The TEM was used to identify areas mapped as wetland ecosystems. The area of wetland within the study area was summarized.

2.1.5 Rare Plants

A preliminary list of rare plants potentially occurring within the general vicinity of MPM is presented in Appendix 1. The list was generated by querying the CDC data for Red- and Blue-listed vascular plant taxa associated with the ICHmk or ICHwk subzones. The query for mosses included taxa associated with the entire ICH zone. The list of potential rare plants includes 46 vascular plants and 25 mosses. Limited reconnaissance-level surveys were conducted by a botanist during field visits of the study area.

The habitat affinities of the potential rare plants listed in Appendix 1 were reviewed and compared with the ecosystems known to be present in the study area. Based on the community descriptions in the relevant provincial guides (Steen and Coupé 1997; MacKenzie and Moran 2004), and a site visit in October of 2014, a list of the ecosystem units with the highest potential for occurrence of rare plant species was generated and used to assess project effects.

2.2 Wildlife

Wildlife species detected during fieldwork after the tailings dam failure (e.g., reconnaissance terrestrial survey, soils monitoring surveys, construction monitoring) are listed in Table 2-2 below. That table is not a complete list of species expected to occur but indicates those that were documented in the vicinity after the tailings dam failure and are likely to be some of the more common species that use the area during fall and winter. A list of bird species expected to occur in the Cariboo region was obtained from the BC Bird Atlas (Bird Studies Canada 2014) and is presented in Appendix 2. This list includes species present in the entire region and not all of them will be, or would have been, found in the vicinity of Polley Lake.

Table 2-2: Wildlife Species Detected During Field Surveys

Scientific Name	English Name	Comments
Mammals		
Alces americanus	Moose	Observed
Odocoileus hemionus	Mule Deer	Observed
Castor canadensis	Beaver	Tracks, cuttings
Canis lupus	Gray Wolf	Tracks
Ursus americanus	Black Bear	Tracks
Puma concolor	Cougar	Tracks
Lynx canadensis	Lynx	Tracks
Vulpes vulpes	Red Fox	Observed
Lontra canadensis	River otter	Observed
Tamiasciurus hudsonicus	Red Squirrel	Observed
Lepus americanus	Snowshoe Hare	Observed
Birds		
Anas platyrhynchos	Mallard	Observed
Bucephala albeola	Bufflehead	Observed
Aythya collaris	Ring-necked Duck	Observed
Bucephala clangula	Common Goldeneye	Observed
Glaucidium gnoma	Northern Pygmy-owl	Heard

Table 2-2 (Cont'd): Wildlife Species Detected During Field Surveys

Scientific Name	English Name	Comments
Picoides villosus	Hairy Woodpecker	Observed
Dryocopus pileatus	Pileated Woodpecker	Cavities observed
Bonasa umbellus	Ruffed Grouse	Observed
Falcipennis canadensis	Spruce Grouse	Observed
Herptiles		
Thamnophis sirtalis	Common Gartersnake	Observed
Pseudacris regilla	Pacific Treefrog	Heard
Anaxyrus boreas	Western Toad	Observed
Rana luteiventris	Columbia spotted frog	Observed

2.2.1 Species at Risk

Species and ecological communities in British Columbia are assigned by the BC Conservation Data Centre to one of three lists, based on their provincial Conservation Status Rank. Red-listed species and ecological communities are Extirpated, Endangered, or Threatened in British Columbia. Blue-listed species and ecological communities are of Special Concern (formerly Vulnerable) and Yellow-listed species and ecological communities are secure (Province of BC 2015).

The list of at-risk terrestrial wildlife for the ICHwk2 and ICHmk3 subzones in the Cariboo region obtained from the BC Conservation Data Centre was refined to include only taxa for which potential habitat was present in the vicinity of the study area. For example, grizzly bear (*Ursus arctos*) was removed from consideration because grizzly bears are not managed by the province in the area west of the west arm of Quesnel Lake as the province considers the species to be extirpated from the local area (Province of BC 2014a). Mountain caribou (*Rangifer tarandus*) was removed from consideration within this assessment as caribou have been extirpated from the area west of the west arm of Quesnel Lake (Province of BC 2014a). Species at risk that are potentially present in the study area are listed in Table 2-3. Brief descriptions of each are provided below.

Table 2-3: At-Risk Terrestrial Wildlife Species Potentially Present in the Study Area

Scientific Name	Common Name	BC List	Other List
Enallagma hageni	Hagen's Bluet	Blue	-
Magnipelta mycophaga	Magnum Mantleslug	Blue	-
Anaxyrus boreas	Western Toad	Blue	SARA Schedule 1 – Special Concern
Ardea herodias herodias	Great Blue Heron, *herodias* subspecies	Blue	-
Chordeiles minor	Common Nighthawk	Yellow	SARA Schedule 1 - Threatened
Contopus cooperi	Olive-sided Flycatcher	Blue	SARA Schedule 1 - Threatened
Gulo gulo luscus	Wolverine, *luscus* subspecies	Blue	-
Myotis lucifugus	Little Brown Myotis	Yellow	SARA Schedule 1 - Endangered
Myotis septentrionalis	Northern Myotis	Blue	SARA Schedule 1 - Endangered
Pekania pennanti	Fisher	Blue	-

- Hagen's bluet (*Enallagma hageni*) is a blue damselfly that inhabits marshy lake edges, slow streams and ponds. It is associated with marsh and fen wetland types and flies in June and July (Royal British Columbia Museum and the Spencer Entomological Museum 2004).
- The magnum mantleslug (*Magnipelta mycophaga*) has rarely been detected in Canada (COSEWIC 2012a). Only 13 records of the species are known for BC, and the closest occurrence to Mount Polley is in Wells Gray Park. COSEWIC (2012a) does not list any surveys for terrestrial gastropods completed near Quesnel Lake. The magnum mantleslug has been found in moist microsites in heavily shaded coniferous forests in the ICH and ESSF biogeoclimatic zones. Individuals have been located both on the ground surface and under bark, logs or rocks. Important habitat features may include seepage sites, coarse woody debris, and undisturbed forests with intact duff layers (COSEWIC 2012a).
- The western toad (*Anaxyrus boreas*) is an amphibian that is widely distributed across the province (COSEWIC 2012b). Adult western toads may be found in a variety of habitats including grasslands, forests, shrublands, riparian areas and wetlands. Adult toads congregate to breed communally in the spring and exhibit fidelity to their breeding sites. Females lay strings of eggs

in stream margins, wetlands, river backchannels, ponds, and human-made sites such as ditches, road ruts, and tailings ponds (COSEWIC 2012b). The eggs hatch into tadpoles that metamorphose in 4-12 weeks and leave the water by late July or August. Adults may move up to several kilometres away from breeding sites, and show a strong fidelity to summer foraging sites. Adult western toads feed on invertebrates including worms (Clitellata), slugs (Gastropoda), spiders (Arachnida), bees (Hymenoptera), beetles (Coleoptera), sow bugs (Isopoda), grasshoppers (Orthoptera), caddisflies (Trichoptera), moths and butterflies (Lepidoptera), flies (Diptera), true bugs (Hemiptera), and ants (Formicidae) (reviewed in COSEWIC 2012b). Larvae eat organic detritus, filamentous algae and carrion (ibid). Adult toads hibernate underground during the winter.

- The Great Blue Heron (*Ardea herodias*) is a large wading bird that feeds on fish, amphibians, small mammals, snakes, and aquatic insects (Gebauer and Moul 2001). The *arodias* subspecies is provincially Blue-listed and is the subspecies present in the Cariboo region. Herons are present in the Cariboo region between April and November (Roberts et al. 2013). During the rest of the year, they winter in southern BC or further south. Herons are colonial nesters and build bulky stick nests in coniferous or deciduous trees. The closest known colony to the study area is the Big Lake FSR colony (Colony 502-005), which was active between 1997 and 1999 and was located 2.4 km west of the north end of Polley Lake (Great Blue Heron Management Team 2015).
- The Common Nighthawk (*Chordeiles minor*) is a brown, black and grey-mottled bird that forages aerially for flying insects. Nighthawks are migratory and may be present in the Cariboo region between the beginning of June and mid-September (Roberts et al. 2013). Nighthawks lay their eggs on the ground in sparsely-vegetated areas and may nest in disturbed sites such as roadsides, gravel pits and recent clear-cuts. They breed from May to September in BC (Campbell et al. 2006).
- The Olive-sided Flycatcher (*Contopus cooperi*) is a robin-sized songbird that frequents forest edges. It forages from a perch on a tree or snag from which it makes short flights in pursuit of flying insects. Olive-sided Flycatchers are migratory and are present in the Cariboo region between May and mid-August (Roberts et al. 2013).
- The wolverine (*Gulo gulo*) is a large mustelid that feeds on a wide variety of prey from small mammals to ungulates. The *luscus* subspecies is provincially Blue-listed and is the subspecies present in the Cariboo region. Although it is associated with high-elevation forests and large areas of wilderness, wolverine distribution is governed more by food supply than by particular habitats. It is both a generalist and an opportunist and will readily scavenge carrion. Wolverines range widely (50-100 km^2 for females and up to 1580 km^2 for males) and may become nomadic if food is scarce (COSEWIC 2014).

- The little brown myotis (*Myotis lucifugus*) and northern myotis (*M. septentrionalis*) are small insectivorous bats that roost in tree cavities, under loose bark, in buildings and in rock fissures. Although the little brown myotis has been described as the most common and widely distributed Canadian bat species (van Zyll de Jong 1985), both it and the northern myotis are now listed under SARA as endangered due to a fungal disease known as white-nose syndrome (Government of Canada 2014). The disease is not currently present in western Canada but is spreading westward from the eastern provinces. The northern myotis is very difficult to distinguish from similar species in the field and its identification must be confirmed via DNA typing. Little brown myotis and one individual field-identified as a northern myotis were captured in 2012 near Spanish Lake (approximately 11 km northeast of the mouth of Hazeltine Creek) (data file at http://a100.gov.bc.ca/pub/siwe/details.do?id=5044). A species account for little brown myotis and northern myotis is presented in Appendix 3.
- The fisher (*Pekania pennanti*) is a large mustelid or weasel. Fishers are forest-dwellers that feed primarily on small mammals. Females require cavities in large deciduous trees for use as reproductive dens. There are large-diameter *Populus balsamifera* present along Hazeltine Creek that are potential natal den sites for fishers. A fisher species account is presented in Appendix 3.

The suitability of the habitats affected by the tailings dam failure was quantified for the species at risk identified in Section 2.2 for which wildlife habitat suitability mapping at 1:50,000 is appropriate. Specifically, habitat suitability ratings were completed for fisher and northern myotis/little brown myotis (grouped as these two bat species use similar roosting habitat). Some species were not suitable candidates for habitat maps. Western toads can breed in ephemeral ponds and ditches that are not mappable at the scale of the TEM, and impacts to breeding ponds along Hazeltine Creek are described in the Fish and Fish Habitat Assessment. Great Blue Herons would primarily forage along Hazeltine Creek and the shorelines of Polley and Quesnel Lakes – also assessed within the Fish and Fish Habitat Assessment – and Olive-sided Flycatchers use tall trees or snags along forested edge habitats. Wolverines are not associated with any particular habitat types (RIC 1999), and there is insufficient information available on habitat requirements of the magnum mantleslug to rate habitat for this species. Hagen's bluet could potentially use any of the wetlands and natural waterbodies within the study area, and Common Nighthawks use sparsely-vegetated habitats for nesting.

2.2.2 Regionally-important Species

The study area is located within Wildlife Management Unit 5-02. Species of regional importance that are not classified as at risk are listed in Province of BC (2014). Those for the Cariboo region include moose, mule deer (*Odocoileus hemionus*) and Bald Eagle (*Haliaeetus leucocephalus*). Other species of economic importance include furbearers, which are commercially trapped by local residents, black bear (*Ursus americanus*), waterfowl, and game birds.

Moose are the largest ungulates native to the Cariboo region, and moose populations in this region are thought to be declining for unknown reasons (McNay et al. 2013). Moose eat a wide variety of browse and other vegetation (reviewed in Keystone Wildlife Research Ltd. 2006). Willows and other deciduous shrubs (Table 2-4) are eaten year-round and aquatic and emergent plants are consumed during the growing season (Shackleton 1999). Moose home ranges in the Cariboo region are 5 to 50 square kilometres (km^2) but 5-10 km^2 is more typical in the winter (Youds 1999). Moose rut during September and October and cows give birth to one to three calves in June (Shackleton 1999). Wolves (*Canis lupus*) and bears (*Ursus* spp.) are the main moose predators in BC (ibid).

Table 2-4: Preferred Moose Forage Plants (Keystone Wildlife Research Ltd. 2006)

Common Name	Scientific Name
Willows	*Salix* spp
Aspen	*Populus tremuloides*
Balsam poplar	*Populus trichocarpa*
Paper birch	*Betula papyrifera*
Subalpine fir	*Abies lasiocarpa*
Douglas maple	*Acer glabrum*
Red-osier dogwood	*Cornus stolonifera*
Saskatoon	*Amelanchier alnifolia*
Snowbrush	*Ceanothus velutinus*
Falsebox	*Paxistima myrsinites*
Chokecherry	*Prunus virginiana,*
Sitka mountain ash	*Sorbus sitchensis*
Hazelnut	*Corylus cornuta*
Bog birch	*Betula glandulosa*

Mule deer are widely distributed across the province and are important game animals for local communities. Mule deer are most likely to occupy the study area during the growing season as deep snowfall limits their presence during the winter. A mule deer species account is presented in Appendix 3.

The Bald Eagle is a large raptor that feeds primarily on fish, waterfowl and carrion. This species is highly adaptable and may occupy diverse habitats. Adults (>5 years of age) are easily recognized by their white head and neck that contrasts with dark body and wings. Bald Eagles in the 100 Mile House forest district nested close to water, mainly in dominant or codominant veteran Douglas-fir (*Pseudotsuga menziesii*) or black cottonwood trees (Packham 2005). Nest sites are re-used from year to year, and nest trees are protected under the BC *Wildlife Act*. One to three young are fledged annually, depending on the amount of food supplied by the parents (Beebe 1974). Management recommendations for eagle habitat in the ICH include the retention of veteran trees suitable as nest trees within 104 m of fish-bearing water (Packham 2005).

Other terrestrial wildlife species of economic importance include commonly-trapped furbearers, upland game birds, waterfowl, and black bear (*Ursus americanus*). Furbearers known or likely present in or near the study area (other than fisher and wolverine, which are discussed above) are listed in Table 2-5. Black bears are hunted by resident and non-resident hunters and are important as meat sources and as trophies for clients of guides and outfitters. Ruffed Grouse (*Bonasa umbellus)* and Spruce Grouse (*Falcipennis canadensis)* are hunted for food and for recreation.

Table 2-5: Furbearers Known or Potentially Present Near the Study Area

English Name	Scientific Name
American mink	*Neovison vison*
Ermine	*Mustela ermine*
long-tailed weasel	*Mustela frenata*
American marten	*Martes americana*
river otter	*Lontra canadensis*
Coyote	*Canis latrans*
red fox	*Vulpes vulpes*
grey wolf	*Canis lupus*
Canada lynx	*Lynx canadensis*
Bobcat	*Lynx rufus*
red squirrel	*Tamiasciurus hudsonicus*
common muskrat	*Ondontra zibethicus*
American beaver	*Castor canadensis*

Areas Managed for Wildlife

Ungulate Winter Range (UWR) and Wildlife Habitat Area (WHA) boundaries near the Mount Polley Mine were obtained from the province (Province of BC 2014a). No UWR for deer, goats, or caribou or WHAs are present within the study area. Mount Polley is located within the very deep snowpack zone where mule deer are not expected to winter (Armleder et al. 1986). The closest UWR is u-5-002, located on the east side of the west arm of Quesnel Lake, approximately 1.4 km across the lake from the mouth of Hazeltine Creek. The closest WHA is WHA 5-106 for mountain caribou, located on higher elevations north and east of Spanish Lake, approximately 17 km from the mouth of Hazeltine Creek.

High-value wetlands for moose have been mapped in the Cariboo region using methodology consistent with provincial standards for wildlife habitat ratings (Intrepid Biological Consulting 2003; Keystone Wildlife Research Ltd. 2006). The wetland mapping includes ratings for both summer and winter moose habitat. Spatial data for that mapping project were obtained from the province and overlain with the study area to quantify the amount of moose wetland habitat affected.

3 IMPACT ASSESSMENT

3.1 *Vegetation*

3.1.1 Terrestrial Ecosystems

Ecosystem Units of the Study Area

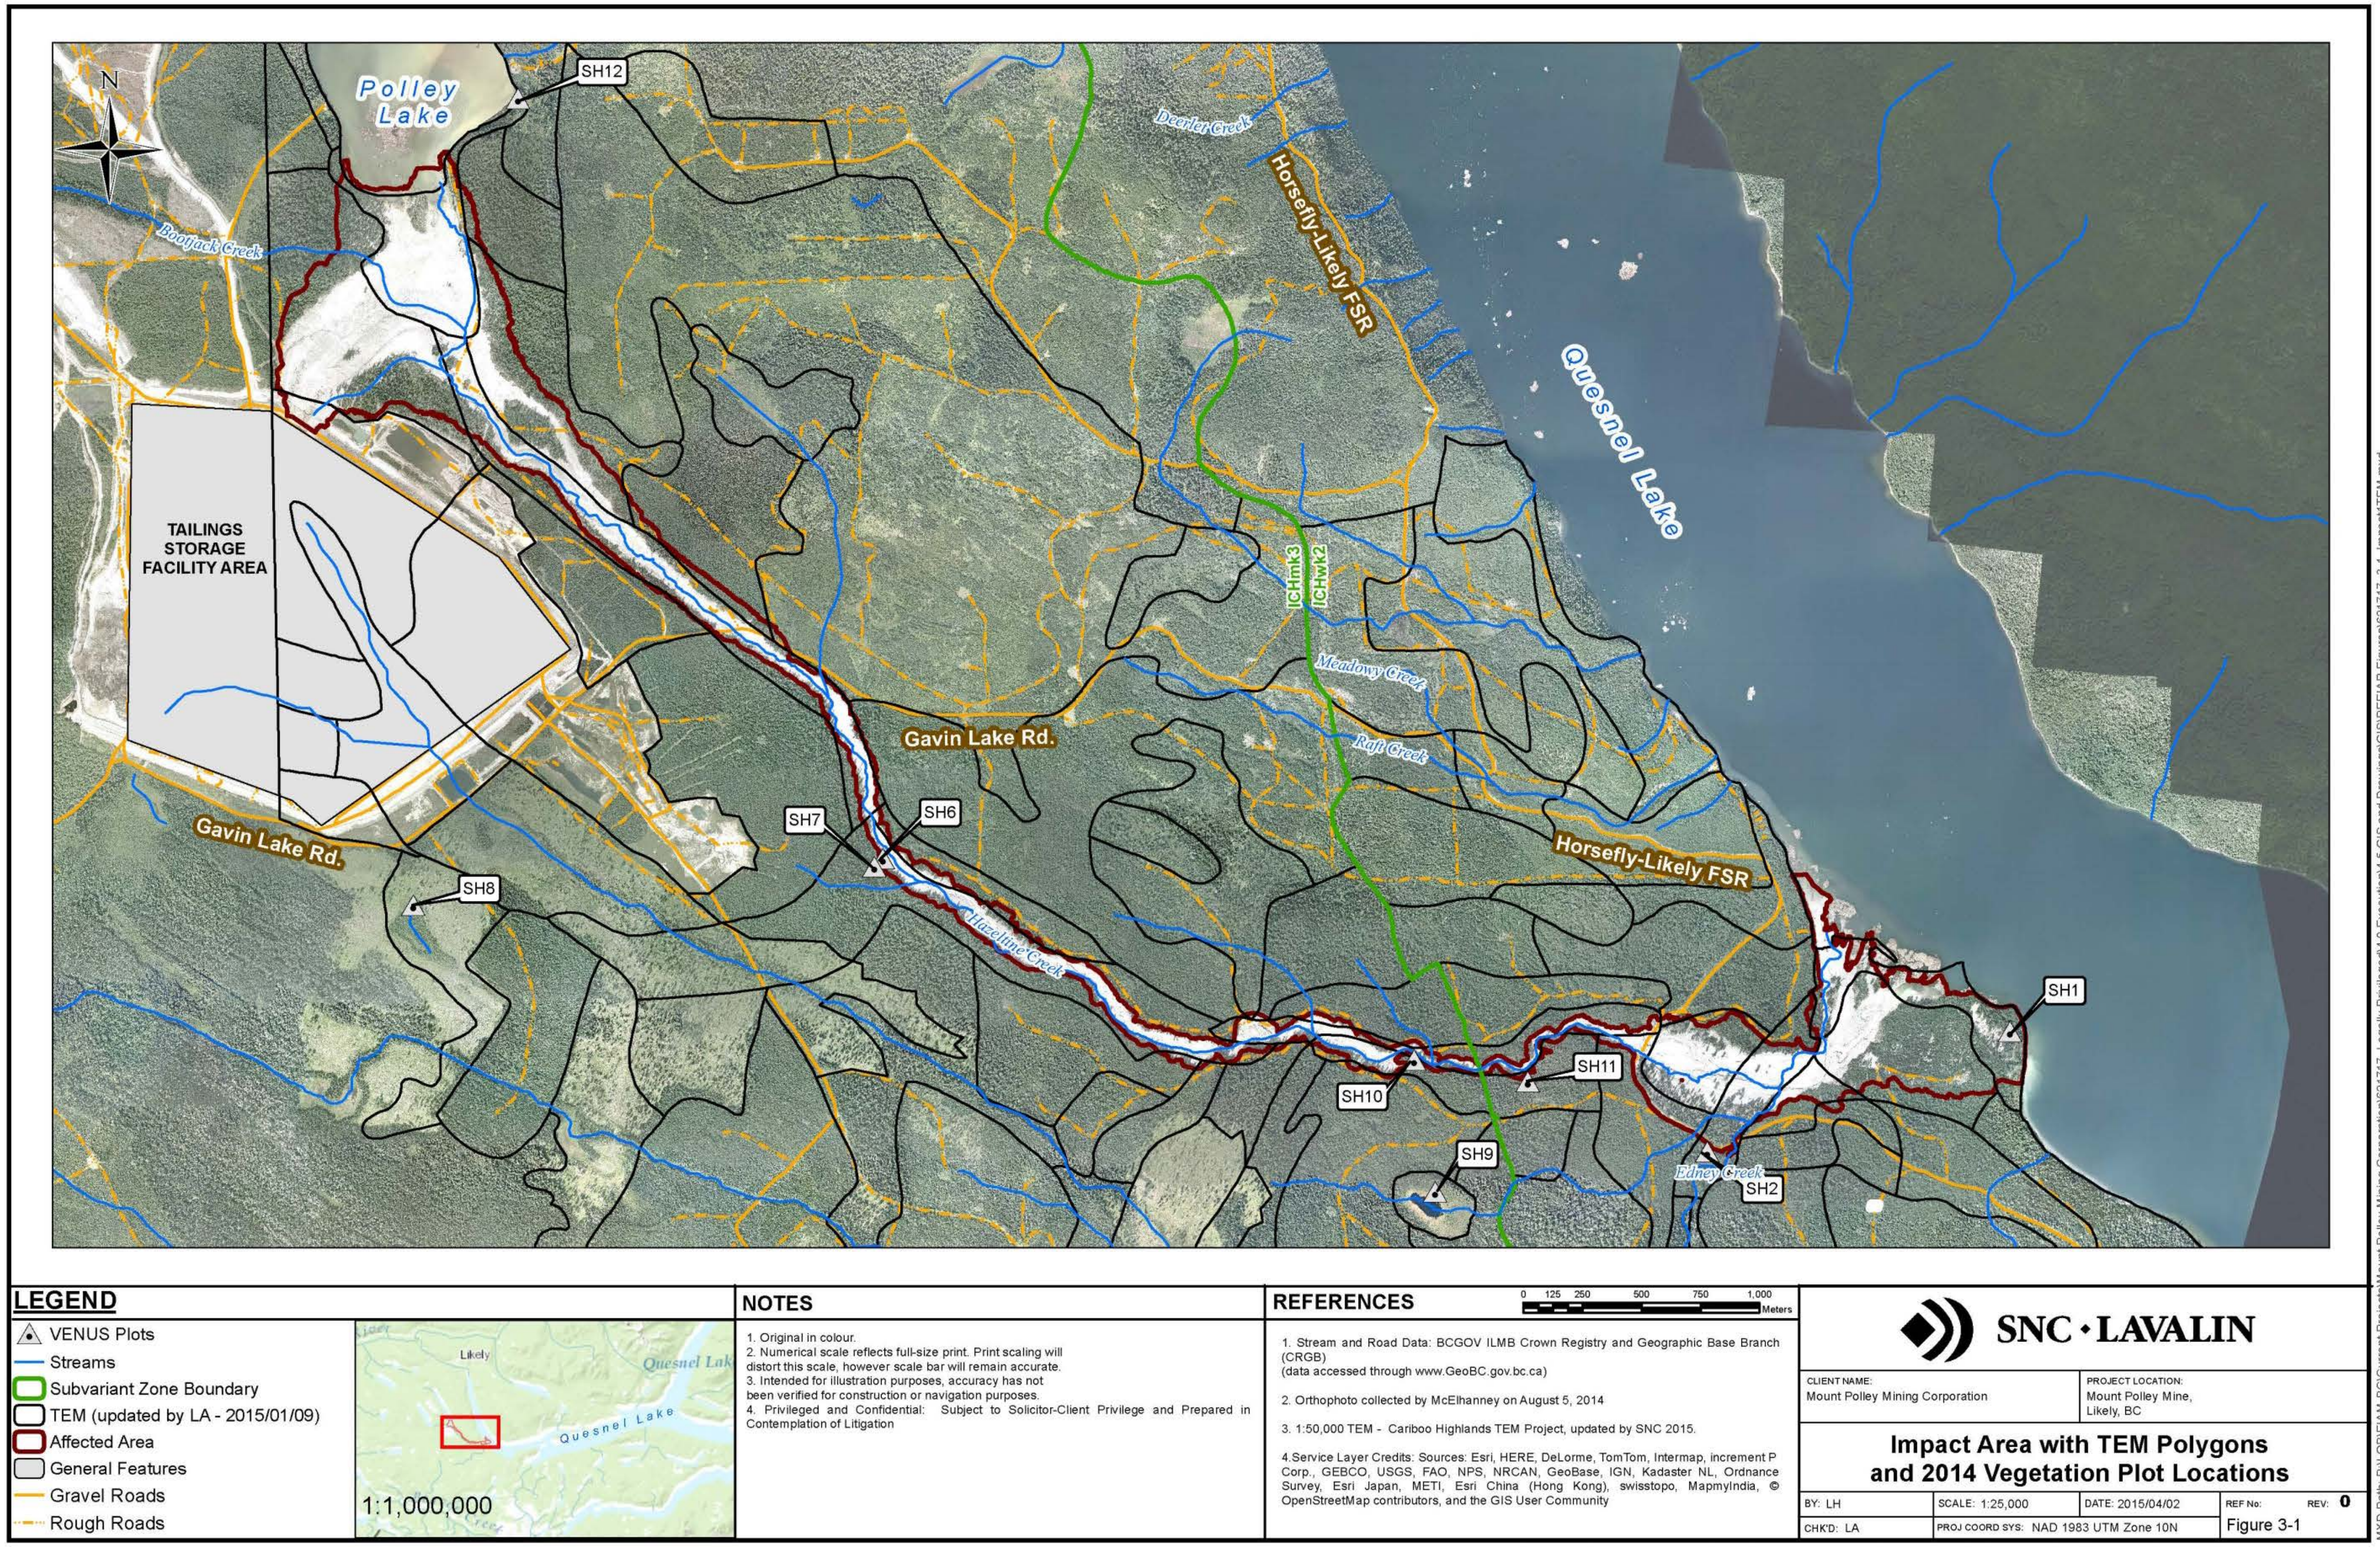
Field Surveys

An assessment of the accuracy of the TEM in the study area was done using 12 plots from the field visits on October 6-8, 2014. Twelve visual or Ground Inspection Form (GIF) plots were completed (Figure 3-1). Plots were generally done in undisturbed vegetation just beyond the boundaries of the deposition zone. The field results were compared to the labels of the TEM polygons in which the plots were located (Table 3-1). The subzone, ecosystem and structural stage of the TEM polygon matched the field plot card for five plots. One plot matched the subzone and structural stage of the TEM but was assessed as a different ecosystem than the one typed in the TEM. One plot less than 200 m from the subzone boundary matched the ecosystem (zonal) and the structural stage, but was judged to be ICHmk3 although the TEM placed it in the ICHwk2. The field data, though limited, indicate that the TEM accuracy is acceptable for the purposes of this assessment.

Table 3-1: Ecosystem Field Plots Compared to Corresponding TEM Labels

'Small Wetland' Plots	Incorrect Wetland Plots	Plots with Ecosystem and Structural Stage Correct	Plots with Subzone and Structural Stage Correct	Plots with Subzone, Ecosystem and Structural Stage Correct	Total Plots
2	3	1	1	5	12

Two plots were done in small wetlands that were minor components of a forested polygon. The labels for the associated TEM polygons did not include any wetland components, but ecosystems making up less than 20% of a polygon are not normally identified in a TEM polygon label according to standard TEM methodology (RIC 1998).



Project Path: P:\LOB\EIAM-BC\Current Projects\Mount Polley Mining Corporation\621717_Legally Privileged\4.0 Execution\4.5 GIS and Drawings\GIS\IA Figures

Figure 3-1: Impact Area with 2014 Field Plots

Three plots in wetland polygons did not match the wetland type mapped. One, on the shores of Polley Lake, was identified as a Ws02 Mountain alder – Pink spirea – Sitka sedge swamp in the field but was located within the LA Lake polygon in the TEM. That disparity is likely to be a function of map scale and/or lake level fluctuation. The remaining two wetland plots were identified in the field as Wb08 Black spruce – Soft-leaved sedge – Peat-moss bog and Wb05 Black spruce – Water sedge – Peat-moss Bog/Poor Fen, but were typed in the TEM as the BS Scrub birch / sedges / peat-mosses fen. Both the Wb08 and Wb05 are sparsely-treed wetlands dominated by scrub birch, Labrador-tea, sedges and peat mosses, very similar to the description of the BS unit. The differences in the map units and the field plots reflect the often-overlapping characteristics of many wetland ecosystems.

Summary of Affected Ecosystems

The total area of terrestrial ecosystems affected by inundation and/or erosion was 234.3 ha (see Section 1.1.1). The ecosystems within the study area are summarized in Table 3-2 below.

Table 3-2: Summary of Ecosystems in the Study Area

<table>
<tr><th>Affected Area</th><th>Biogeoclimatic Subzone Variant</th><th>Ecosystem Name (Site Series)</th><th>Ecosystem Symbol and Structural Stage</th><th>Total (ha)</th></tr>

Grand Total				**234.3**

As described in the Soil Quality Impact Assessment, the tailings dam failure removed existing vegetation, altered soil conditions, and changed hydrologic flow patterns within the study area. This creates conditions for early seral plant species (both native and non-native) to colonize these areas. As succession proceeds, the native early-colonizers are typically replaced with mid- and late-seral species, but some of the non-natives can persist and affect plant community structure and composition for years. Invasive weed species that have been documented at the MPM (Mount Polley Mining Corporation 2013, 2014) include oxeye daisy (*Chrysanthemum leucanthemum*), white cockle (*Lychnis alba*), thistles (*Cirsium* spp.), curled dock (*Rumex crispus*), scentless camomile (*Matricaria maritima*), pigweed (*Amaranthus retroflexus*), Dalmatian toadflax (*Linaria dalmatica*), pineapple weed (*Matricaria discoidea*), yellow hawkweed (*Hieracium* spp.), and dandelion (*Taraxacum officinale*).

It is difficult to predict how the altered soil conditions in the study area will affect primary succession in terms of the plant communities that will develop. 'Tremendous variability in succession' has been noted following large-scale disturbances (Turner et al. 1998). In general, disturbance (including both anthropogenic disturbance and natural events such as landslides) promotes the establishment of non-native weedy species (Hobbs and Huenneke 1992; Walker et al. 2009), and it is reasonable to assume that this will likely be the case in the study area. Ongoing reclamation activities that consider the processes of succession of natural disturbances (Polster 2009) should help to control the establishment and spread of weeds, and promote restoration of functional ecosystems that are resistant to non-native species invasion.

As described in the Soil Quality Impact Assessment, changes to soil thermal and moisture regimes are expected to occur. Those alterations as well as differences in topsoil distribution will affect the decomposition of organic matter and nutrient cycling, which may have long-term impacts related to plant nutrient availability and ecological function. Where topsoil has been inundated, the availability of its nutrients to plants and to soil fauna would be expected to diminish as the thickness of the deposited tailings layer increases, as thicker deposits will bury the topsoil layer beyond the rooting depths of most species. Analysis presented in the Soil Quality Impact Assessment indicates that the tailings in the study area have higher pH levels, lower soil nutrient levels, and increased metal concentrations compared to the background soils immediately adjacent. This altered edaphic environment, especially when combined with the physical landform modifications such as scouring and changes in drainage, is expected to affect the future regeneration of ecosystems in the study area. The long-term impacts on ecosystems will be the subject of the ERA.

3.1.2 Rare Ecological Communities

One Red-listed and two Blue-listed communities are defined for the mapped ecosystems within the ICHmk3 subzone variant that overlap the study area (BC Conservation Data Centre 2014a). None of the mapped ecosystems within the ICHwk2 subzone that overlap the study area are provincially listed as at-risk. Brief descriptions of each of the at-risk ecological communities are provided below.

Scrub Birch / Sedges / Peat-Mosses

This fen community is provincially Red-listed, and has not been associated with a particular site series in the ICHmk3 by the CDC. A site description provided by the CDC (2014b) is as follows:

> This is a wetland community with very low productivity. The soils are organic and seepage is commonly present above 20 cm. It occurs in areas of cold-air ponding or cold air drainage (Delong 2003).
>
> *Pinus contorta* (lodgepole pine) cover does not usually exceed five percent. Shrub cover is low to moderate, consisting of *Betula nana* (scrub birch), *Lonicera involucrata* (black twinberry), [*Rhododendron groenlandicum* (Labrador-tea)] and various willows. The herb cover may be as high as seventy percent, dominated primarily by *Carex* spp. (sedges). Other herbs present may include *Equisetum arvense* (common horsetail), *Senecio triangularis* (arrow-leaved groundsel), and *Gaultheria hispidula* (creeping snowberry). The moss layer is well developed with up to 65 percent cover, dominated by *Sphagnum* spp. (sphagnum species), *Pleurozium schreberi* (red-stemmed feathermoss), and *Aulacomnium palustre* (glow-moss).

A similar wetland TEM unit was mapped in the ICHmk3. The BS Scrub birch-Sedge-Sphagnum wetland is briefly described in the TEM expanded legend (Geowest Environmental Consultants Ltd. 2001) as a nutrient-poor organic wetland in depressions with a near surface water table. It is dominated by sphagnum mosses, scrub birch and sedges, and associate species are listed as Labrador-tea, marsh cinquefoil and bog cranberry. There are 4.9 ha mapped as the ICHmk3 BS unit within the study area, in the Polley Plug and Upper Hazeltine affected areas. It cannot be confirmed that the now-removed BS wetlands contained the Red-listed wetland community but it is possible given the similarity of the two ecosystems.

Western Redcedar / Oak Fern / Electrified Cat's-Tail Moss

This forested community is provincially Blue-listed and is associated with the 04 site series in the ICHmk3 subzone. A site description of the 04 site series is provided by Steen and Coupé (1997):

> ...occurs on sites that are slightly more moist (mesic-subhygric) than zonal sites. They occur primarily on mid and lower slope positions where they receive low volumes of intermittent seepage. Soils are frequently mottled and forest floors are relatively thick (7 - 12 cm). The forest canopy is moderately closed and dominated by redcedar, with subalpine fir and hybrid white spruce in the lower canopy. Regeneration is dominated by redcedar and is often moderately dense. In addition to species common on zonal sites, characteristic species on these sites include devil's club [*Oplopanax horridus*], oak fern [*Gymnocarpium dryopteris*], rosy twistedstalk [*Streptopus lanceolatus*], and sweet-scented bedstraw [*Galium triflorum*]. The moss layer is typically well developed and dominated by electrified cat's-tail moss [*Rhytidiadelphis triquetris*], woodsy ragged moss [*Brachythecium hylotapetum*], and leafy mosses [*Mnium* spp.].

The 04 site series in the ICHmk3 subzone variant was mapped as the SO map unit. In total, 53.4 ha of the SO ecosystem was mapped in the study area, in the Polley Plug and Upper Hazeltine Creek remediation units.

Western Redcedar / Falsebox

This forested community is provincially Blue-listed and is associated with the 01 site series in the ICHmk3. The 01 site series is the most common site series within a biogeoclimatic subzone variant. A description of the 01 site series is provided by Steen and Coupé (1997):

> ...dominates the ICHmk3 landscape. It occurs on gentle to moderately sloping terrain with deep, medium-textured soils. Late seral and climax stands have closed canopies dominated by western redcedar and subalpine fir. Hybrid white spruce is frequently scattered throughout the stand. Western hemlock rarely occurs in the overstory and only occasionally occurs in the understory. A very dense cover of redcedar and subalpine fir regeneration is a characteristic. Seral stands are frequently dominated by Douglas-fir and lodgepole pine. Paper birch [*Betula papyrifera*] is frequently present in seral stands and occasionally forms nearly pure stands. The undergrowth, except for the dense regeneration layer, contains a moderate to sparse cover of falsebox and black huckleberry [*Vaccinium membranaceum*] as well as several forbs including wild sarsaparilla [*Aralia nudicaulis*], foamflower [*Tiarella trifoliata*], queen's cup [*Clintonia uniflora*], bunchberry, twinflower [*Linnaea borealis*], and five-leaved bramble [*Rubus pedatus*]. Ferns are generally lacking. The moss layer usually forms a nearly continuous carpet dominated by red-stemmed feathermoss, step moss, and knight's plume.

The 01 site series was mapped as the RF map unit. In total, 29.5 ha of RF was mapped in the study area, in the Polley Plug, Canyon Hazeltine Creek and Upper Hazeltine Creek affected areas.

In summary, the total area of the study area mapped as site series associated with Blue-listed forested communities is 81.9 ha (Table 3-2). An additional 4.9 ha may have been a Red-listed wetland community.

3.1.3 Old-growth Forest and Old-Growth Management Areas

OGMA targets for the Polley Landscape Unit were met before the tailings dam failure (C. Webb, pers. comm. 2015). Designated permanent OGMAs along Hazeltine Creek, Bootjack Creek and Edney Creek were affected by the tailings dam failure as observed during field visits, ranging in intensity from complete loss (erosion of the soil and/or loss of all vegetation cover, including trees) to deposition of a shallow layer of tailings on the ground surface with retention of tree and shrub cover.

The area of OGMA within the study area totals slightly over 200 ha. A summary of the amount of OGMAs affected is provided in Table 3-3 below, and in Figure 3-2.

Table 3-3: Summary of Old Growth Management Areas in the study area

Affected Area	Biogeoclimatic Subzone Variant		Grand Total (ha)
	ICHmk3	ICHwk2	
Canyon Hazeltine Creek Total	2.2	2.5	4.7
Edney Creek Mouth Total	0.0	2.3	2.3
Lower Hazeltine Creek	0.0	51.8	51.8
Polley Plug Total	15.3	0.0	15.3
Upper Hazeltine Creek Total	126.3	0.0	126.3
Grand Total	**143.8**	**56.6**	**200.3**

Old growth (structural stage 7) mapped in the study area (both within and outside of OGMAs) totalled 41 ha. Tailings deposition may affect old forest values in the OGMAs through several pathways. Depending on the depth of the deposition layer, the survival of certain individual trees may be threatened. Research on flood events in riparian zones suggest that certain species tolerate alluvial deposition better than others (Stone and Vasey 1968; Hukusima and Yoshikawa 1997). Tree species adapted to repeated alluvial deposition, such as cottonwoods, would be expected to resist the effects of tailings deposition better than non-riparian species. Cottonwoods develop adventitious roots in response to deposition events, which research suggests may play a role in their survival (Schier and Campbell 1976; Krasny et al. 1998; Yoshikawa and Hukusima 1997).

Figure 3-2: OGMAs and High-Value Wetlands Affected by the Tailings Dam Failure

Project Path: P:\LOB\EIAM-BC\Current Projects\Mount Polley Mining Corporation\621717_Legally Privileged\4.0 Execution\4.5 GIS and Drawings\GIS\IA Figures

3.1.4 Wetlands

The only wetland mapped within the study area is the 00/BS (Scrub birch/ Sedges/ Peat-mosses) unit. The study area includes 4.9 ha of this ecosystem, in both the ICHmk3 and ICHwk2 subzone variants (Table 3-2).

3.1.5 Rare Plants

Impacts on specific rare plant occurrences cannot be quantified due to the physical changes in the study area resulting from the tailings dam failure. There are no occurrence records for rare plants within the study area; however, no rare plant surveys are known to have been performed there before the tailings dam failure. No rare plants were detected during reconnaissance field surveys in and around the study area following the tailings dam failure, but the timing of the surveys was poor, as most plants are dormant or senescent at the beginning of October. Based on the review of rare plant habitat affinities, it was determined that six ecosystem units had the highest potential for occurrence of rare plant species (Table 3-4). These were primarily the wetter site series (hygric to hydric soils) associated with creeks, lakes and wetlands. A total of 85.8 ha in the study area were mapped as higher-potential rare plant habitats. It should be noted that this is only a coarse-level analysis of rare plant potential. It has not been conclusively determined that rare plants occur in the identified ecosystems, or that they would not be found in the lower-potential ecosystems.

Table 3-4: Ecosystems in the Study Area with a Higher Potential for Occurrence of Rare Plants

Remediation Unit	Biogeoclimatic Subzone Variant	Ecosystem Name (Site Series)	Ecosystem Symbol and Structural Stage	Total (ha)
Edney Creek Mouth	ICHwk2	Sxw-Twinberry-Oak fern (06)	ST6	1.6
Lower Hazeltine Creek	ICHwk2	CwHw-Devil's club-Lady fern (07)	RD4	17.5
		Sxw-Twinberry-Oak fern (06)	ST6	22.2
		Willow-Red-osier dogwood floodplain (00)	WDn3b	5.5
Polley Plug	ICHmk3	Scrub birch-Sedge-Sphagnum (00)	BS3a	3.0
Polley Plug	ICHmk3	Lake (00)	LA	1.9
		CwSxw-Devil's club-Horsetail (07)	RHp6	12.0

Table 3-4 (Cont'd): Ecosystems in the Study Area with a Higher Potential for Occurrence of Rare Plants

Remediation Unit	Biogeoclimatic Subzone Variant	Ecosystem Name (Site Series)	Ecosystem Symbol and Structural Stage	Total (ha)
Upper Hazeltine Creek	ICHmk3	Scrub birch-Sedge-Sphagnum (00)	BS3a	1.9
		Lake (00)	LA	0.4
		CwHw-Devil's club-Lady fern (06)	RD7	9.2
		CwSxw-Devil's club-Horsetail (07)	RHp6	7.5
		Snowberry-Red-osier dogwood floodplain (00)	WD3a	3.1
Grand Total				**22.1**

Potential effects of the tailings dam failure on rare plants include:

- removal of existing rare plant occurrences in the tailings deposition zone;
- reduced extent and/or vigour of existing rare plant occurrences;
- reduced long-term viability of existing rare plant occurrences; and
- reduced suitability of unoccupied rare plant habitat.

If rare plants were present in the study area, The largest impacts to rare plant occurrences (if any) would have likely taken place immediately following the tailings dam failure when occurrences were removed due to burial or scouring.

Rare plants, if any, surviving in the study area would face altered habitat conditions in some areas that could reduce their viability. Rare plants are often habitat specialists and require a narrow range of edaphic, biotic, and climatic conditions to survive (Williams et al. 2009; Lomba *et al*. 2010). Comparative soil analyses of the tailings deposits indicate that, compared to the background soils immediately adjacent, the tailings show higher pH levels, lower soil nutrient levels, and increased metal concentrations. This altered edaphic environment, especially when combined with the physical modifications brought about by the tailings dam failure, would be expected to reduce the viability, and perhaps eliminate, rare plant occurrences remaining in the study area.

Likewise, the suitability of any existing unoccupied rare plant habitat in the study area would have been altered by the tailings dam failure. Tailings deposition, vegetation removal, and topsoil scouring have dramatically changed the land's potential to support colonization by rare plants. The range of potential impacts to rare plants from tailings deposition on topsoil resources will likely vary depending on the rooting depths of the species. However, the exact nature of these changes on future habitat suitability is difficult to predict. Studies on large infrequent disturbances show that primary and secondary succession following major disturbance events such as landslides and volcanic eruptions is often complex and proceeds in unexpected ways (Turner et al. 1998; Crisafulli et al. 2005). Rare plant habitat suitability would be expected to develop over time along similar complex pathways.

3.2 Wildlife

Potential effects of the tailings dam failure on wildlife include:

- habitat loss from tailings deposition and erosion;
- mortality from burial by tailings and debris;
- changes to food supply from effects to fish and other aquatic prey; and
- adverse health effects from exposure to increased levels of metals.

Interim results from the Geochemical Characterization of Spilled Tailings report [SRK Consulting (Canada) Inc. 2015] indicate that the tailings are not acid-generating or leachable. The potential for long-term effects on wildlife from changes to soil chemistry and exposure to metals will be addressed as part of the ERA planned for later in 2015.

The flood of tailings and debris from the tailings dam failure would likely have resulted in some degree of wildlife mortality but the extent of that mortality is impossible to quantify. Large and/or highly mobile species may have been able to avoid the flow but small species such as amphibians, snakes and small mammals (especially burrowing species) may not have been able to escape the flow from the tailings dam failure. Some organisms would likely have survived on refugia (e.g., undisturbed 'islands', in or on trees that remained standing, inside large logs) providing sources for recolonization of the area. Variations in topography would have resulted in corresponding variation in impacts, with differences in the amount of debris deposited. More wildlife would likely have survived where thinner layers were deposited by the debris flow (Crisafulli *et al.* 2005).

The tailings dam failure occurred on August 4, a date when most bird species in the area have already completed nesting for the year (Environment Canada 2014). Impacts on active nests are less likely than if the failure had occurred earlier in the growing season. Ground nests – such as those of Common Nighthawk - in the flow path would have been lost. Elevated nests – potentially including those of Olive-sided Flycatcher - may have been lost when shrubs and trees were uprooted by the flow and by erosion (Figure 3-3). Falling trees may have resulted in mortality of tree-roosting bats. Wildlife mortality was not observed, but it cannot be discounted, as any remains of small animals would likely have been buried under sediment and debris.

Figure 3-3: Large *Populus* Uprooted by Erosion along Stream Channel

3.2.1 Species at Risk

The impacts on species at risk cannot be quantified as no previous detailed surveys occurred before the tailings dam failure to document species presence and assess specific habitat suitability in the study area affected by the dam failure. The list of at-risk species potentially affected (see 2.2.1) is based on potential occurrence. Species presence and the timing and duration of their residence in the study area will vary according to habitat characteristics as well as factors such as natural and anthropogenic mortality, social interactions, timing of life history events, seasonal and inter-annual variation in habitat use, population cycling, migration routes and timing, and weather. Habitat losses can be directly quantified and can help guide mitigation strategies that increase, enhance, or replace the habitat degraded.

The likelihood of direct mortality of species at risk from the physical effects of the tailings dam failure can be inferred from the habitat types lost. Western toads were documented near the study area during field visits (see Table 2-2) and were probably present in the affected habitats. Their presence suggests they could recolonize the study area if suitable habitat was restored. The beaver ponds documented in Hazeltine and Edney creeks (see Fish and Fish Habitat Assessment) may have provided breeding habitat for toads. Toads are slow-moving and it is likely that individual animals were buried by the flood of sediment and debris. Sediment can bury and smother amphibian eggs, and increased sediment loads were found to decrease survival of western toad tadpoles under laboratory conditions (Wood 2007).

Hagen's bluet may also have used the wetlands within the study area, but the range of this species is poorly documented and there are no records for it in the vicinity of MPM. The lack of available data on distribution and habitat of the magnum mantleslug precludes an assessment of potential impacts of habitat loss on this species.

The large old trees found in older riparian forests are attractive as roosting habitat for bats (Barclay and Kurta 2007). Tree-roosting bats may have been killed when large trees were uprooted (Figure 3-3) during the debris flow. Mortality to the other species listed in Table 2-3 from the physical effects of the tailings dam failure is less likely as the remaining species would have been able to escape the flow.

The potential for effects on Great Blue Herons due to habitat loss is considered to be low as no nesting colonies were known to be affected. Changes in fish and amphibian numbers or availability may affect the food supply for Great Blue Herons at the local level (Hazeltine Creek). There may be impacts of the tailings dam failure on recruitment of the Polley Lake population of Rainbow Trout (*Oncorhynchus mykiss;* see Fish and Fish Habitat Impact Assessment). Herons take a variety of fish species as prey and the level of dependence of local herons on Rainbow Trout in particular is unknown. The potential for long-term effects on herons will be assessed in the ERA.

Loss of treed habitats will decrease the amount of potential nesting habitat available for Olive-sided Flycatcher. Conversely, the loss of vegetation cover may produce nesting habitat suitable for Common Nighthawks, which are known to nest on gravelled areas, log sorts, abandoned industrial areas and other habitats with bare soil and sparse vegetation (Campbell et al. 2006).

The potential for effects on wolverines due to habitat loss is low. Wolverines travel widely in search of food and are not restricted to particular habitat types (COSEWIC 2014). The study area is very small in proportion to the size of a wolverine's home range.

The habitat suitability for fishers within the study area is presented in Table 3-5. Approximately 90 ha of moderate-suitability fisher reproducing habitat was present in the study area. Female fishers in BC occupy home ranges that are generally over 23 km^2 in size (Weir and Almuedo 2010).

Table 3-5: Habitat suitability for fisher (Reproducing-birthing)

Habitat Suitability Rating	Area Affected (ha)
Moderate	87.7
Low	86.2
Nil	60.4
Grand Total	*234.3*

The habitat suitability for the little brown myotis and northern myotis within the study area is presented in Table 3-6. Approximately 88 ha of high-suitability and 87 ha of moderate-suitability security-thermal (roosting) habitat were present in the study area. Habitat losses of this magnitude are not anticipated to affect regional populations of little brown myotis or northern myotis.

Table 3-6: Habitat suitability for *Myotis* bats (security-thermal)

Habitat Suitability Rating	Area Affected (ha)
High	87.6
Moderate	86.8
Low	42.0
Nil	17.9
Grand Total	*234.3*

Little brown myotis and northern myotis forage on flying insects, including the adult stages of aquatic insects such as caddisflies. Aquatic insect numbers may potentially be affected by changes in water quality such as increased sedimentation (See Fish and Fish Habitat Impact Assessment).

3.2.2 Regionally-important Species

Tailings were deposited over a polygon of identified moose habitat at the south end of Polley Lake (Figure 3-2). The 25.3 ha polygon had been rated as Class 3 (Moderate) for both winter capability and suitability, and as Class 2 (moderately high) summer suitability. The moose habitat polygon overlaps with a TEM polygon mapped as 80% RH (CwSxw-Devil's club-Horsetail) in structural stage 6 (mature forest) and 20% BS (Scrub birch-Sedge-Sphagnum) in structural stage 3a (low shrub). The loss of the wetland may affect the local movement patterns of individual moose but is not expected to affect regional moose populations.

The growing-season habitat suitability for mule deer within the study area is presented in Table 3-7. Approximately 53 ha of moderately-high suitability security-thermal habitat and 163 ha of moderate-suitability security-thermal habitat was present in the study area. There were 62 ha of moderately-high suitability feeding habitat and 114 ha of moderate-suitability feeding habitat in the study area. Ungulate winter ranges are considered critical habitats for ungulates (Safford 2004) but growing season habitat is not usually considered limiting for mule deer in BC. The loss of growing-season habitat due to the tailings dam failure is not expected to affect regional deer populations. No winter range for mule deer has been identified in the study area.

Table 3-7: Habitat Suitability for Mule Deer in the Growing Season

Habitat Suitability Rating	Area Affected (ha)
Security-Thermal Habitat	
2	53.0
3	163.4
4	13.5
6	4.4
Grand Total	*234.3*
Feeding habitat	
2	61.5
3	114.2
4	56.1
6	2.3
Grand Total	*234.2*

No Bald Eagle nests were documented in the study area before the failure occurred but due to lack of previous surveys, the possible presence of a nest cannot be ruled out. Eagles may use a variety of treed habitats as roosting sites. The loss of roosting habitat is not likely to affect eagle numbers. Changes in fish numbers or availability (see Fish and Fish Habitat Assessment) may also affect eagles. Bald Eagles can take a variety of fish species as prey (Blood and Anweiler 1994) and the importance of Rainbow Trout in the diet of eagles that use the study area is unknown.

Polley Lake, Edney Creek and Hazeltine Creek would have provided suitable habitat for beaver and for river otter. Both species are mainly restricted to waterbodies and the riparian habitats around them. Beaver ponds were noted in Edney Creek and in Reach 2 of Hazeltine Creek (see Fish and Fish Habitat Impact Assessment). Mortality of beavers from the debris flow is possible although the numbers of animals lost cannot be confirmed. An average of five animals per colony is used when assessing beaver populations in the province (Hatler and Beal 2003).

The other furbearer species listed in Table 2-5) may also have used the forested habitats that were present within the study area. The physical habitat changes from the tailings dam failure are unlikely to result in population impacts to furbearers at the regional scale. Local effects are possible for species with relatively small home ranges, such as red squirrels, and those that are associated with riparian habitats, such as beaver and mink. Quantification of shoreline and aquatic habitats affected by the dam failure is provided in the Fish and Fish Habitat Impact Assessment and is reproduced in Table 3-8: Areas of Aquatic and Riparian Habitat Affected by the Tailings Dam Failure (from Fish and Fish Habitat Impact Assessment).

Table 3-8: Areas of Aquatic and Riparian Habitat Affected by the Tailings Dam Failure (from Fish and Fish Habitat Impact Assessment)

Water Body	Area of Aquatic Habitat Affected (m^2)	Area of Riparian Habitat Affected (m^2)	Length of Shoreline Affected (m)	Littoral Area Affected (m^3)
Hazeltine Creek	62,616	712,741	-	-
Edney Creek	2,390	20,215	-	-
Quesnel Lake	-	-	2,081	94,394

Black bears are generalists in terms of both their habitat use and diet. Bears have been sighted in the Hazeltine Creek channel during restoration work. The study area is no longer suitable as bear foraging habitat. If the study area is revegetated with bear forage species (either naturally or through remediation planting), bears may be attracted to the study area for feeding. Bears that use open areas are at greater risk of being killed by legal or illegal hunting unless access management is employed to restrict human access to the study area (Cristescu et al. 2012).

The grouse in the study area can use a variety of forested habitat types. The tailings dam failure has resulted in habitat losses for grouse. The habitat effects are not likely to result in effects to regional populations based on the size of the study area and the amount of alternative habitat available. There may be impacts to waterfowl related to the changes in aquatic systems, including changes in numbers and availability of some forage fish species (see Aquatic Impact Assessment and Fish and Fish Habitat Impact Assessment).

Areas Managed for Wildlife

No Wildlife Habitat Areas or Ungulate Winter Ranges were affected as none have been delineated by the province within 1 km of the study area boundaries.

4 RECOMMENDATIONS FOR ADDITIONAL WORK

The duration of the impacts of the tailings dam failure to ecosystems and wildlife will be dependent on the nature and success of the remediation works. The characterization of terrestrial effects should be reassessed once the remediation plan is completed. The potential effects of changes in levels of metals in water and soil are still undetermined. The ERA will consider the implications of these changes on terrestrial ecosystems and wildlife at a future date.

8 NOTICE TO READER

This report has been prepared and the work referred to in this report have been undertaken by SNC-Lavalin Inc. (SNC-Lavalin) for the exclusive use of Mount Polley Mining Corporation, who has been party to the development of the scope of work and understands its limitations. The methodology, findings, conclusions and recommendations in this report are based solely upon the scope of work and subject to the time and budgetary considerations described in the proposal and/or contract pursuant to which this report was issued. Any use, reliance on, or decision made by a third party based on this report is the sole responsibility of such third party. SNC-Lavalin accepts no liability or responsibility for any damages that may be suffered or incurred by any third party as a result of the use of, reliance on, or any decision made based on this report.

The findings, conclusions and recommendations in this report (i) have been developed in a manner consistent with the level of skill normally exercised by professionals currently practicing under similar conditions in the area, and (ii) reflect SNC-Lavalin's best judgment based on information available at the time of preparation of this report. No other warranties, either expressed or implied, are made as to the professional services provided under the terms of our original contract and included in this report. The findings and conclusions contained in this report are valid only as of the date of this report and may be based, in part, upon information provided by others. If any of the information is inaccurate, new information is discovered, site conditions change or applicable standards are amended, modifications to this report may be necessary.

This report must be read as a whole, as sections taken out of context may be misleading. If discrepancies occur between the preliminary (draft) and final version of this report, it is the final version that takes precedence. Nothing in this report is intended to constitute or provide a legal opinion.

The contents of this report are confidential and proprietary. Other than by Mount Polley Mining Corporation, copying or distribution of this report or use of or reliance on the information contained herein, in whole or in part, is not permitted without the express written permission of Mount Polley Mining Corporation.

APPENDIX 1

Rare Vascular Plants and Mosses Potentially Occurring Within the General Area

Rare Vascular Plants and Mosses Potentially Occurring Within the General Area

Scientific Name	Common Name	BC List	Comments
Agastache urticifolia	Nettle-leaved Giant-hyssop	Blue	Vascular plant
Agoseris lackschewitzii	Pink Agoseris	Blue	Vascular plant
Antennaria corymbosa	Flat-top Pussytoes	Red	Vascular plant
Botrychium crenulatum	Dainty Moonwort	Blue	Vascular plant
Botrychium montanum	Mountain Moonwort	Red	Vascular plant
Botrychium simplex var. *compositum*	Least Moonwort	Blue	Vascular plant
Carex crawei	Crawe's Sedge	Blue	Vascular plant
Carex geyeri	Elk Sedge	Blue	Vascular plant
Carex membranacea	Fragile Sedge	Blue	Vascular plant
Carex tenera	Tender Sedge	Blue	Vascular plant
Castilleja gracillima	Slender Paintbrush	Blue	Vascular plant
Chenopodium atrovirens	Dark Lamb's-quarters	Red	Vascular plant
Cryptantha ambigua	Obscure Cryptantha	Blue	Vascular plant
Delphinium sutherlandii	Sutherland's Larkspur	Blue	Vascular plant
Dicentra uniflora	Steer's Head	Blue	Vascular plant
Dryopteris cristata	Crested Wood Fern	Blue	Vascular plant
Eleocharis elliptica	Elliptic Spike-rush	Blue	Vascular plant
Elodea nuttallii	Nuttall's Waterweed	Blue	Vascular plant
Epilobium halleanum	Hall's Willowherb	Blue	Vascular plant
Epilobium x treleasianum	Trelease's Hybrid Willowherb	Blue	Vascular plant
Floerkea proserpinacoides	False-mermaid	Blue	Vascular plant
Galium labradoricum	Northern Bog Bedstraw	Blue	Vascular plant
Gayophytum humile	Dwarf Groundsmoke	Blue	Vascular plant
Gentianopsis macounii	Macoun's Fringed Gentian	Blue	Vascular plant
Hypericum scouleri ssp. *nortoniae*	Western St. John's-wort	Blue	Vascular plant
Juncus confusus	Colorado Rush	Red	Vascular plant

Scientific Name	Common Name	BC List	Comments
Lappula occidentalis var. *cupulata*	Western Stickseed	Red	Vascular plant
Leptosiphon septentrionalis	Northern Linanthus	Blue	Vascular plant
Lomatium sandbergii	Sandberg's Desert-parsley	Blue	Vascular plant
Melica spectabilis	Purple Oniongrass	Blue	Vascular plant
Mimulus breviflorus	Short-flowered Monkey-flower	Blue	Vascular plant
Mimulus breweri	Brewer's Monkey-flower	Blue	Vascular plant
Mimulus patulus	Stalk-leaved Monkey-flower	Red	Vascular plant
Navarretia intertexta	Needle-leaved Navarretia	Red	Vascular plant
Orobanche corymbosa ssp. *mutabilis*	Flat-topped Broomrape	Blue	Vascular plant
Pedicularis parviflora ssp. *parviflora*	Small-flowered Lousewort	Blue	Vascular plant
Pinus albicaulis	Whitebark Pine	Blue	Vascular plant; SARA Schedule 1- Endangered
Polygonum polygaloides ssp. *confertiflorum*	Close-flowered Knotweed	Red	Vascular plant
Polygonum polygaloides ssp. *kelloggii*	Kellogg's Knotweed	Blue	Vascular plant
Ranunculus pedatifidus ssp. *affinis*	Birdfoot Buttercup	Blue	Vascular plant
Salix boothii	Booth's Willow	Blue	Vascular plant
Senecio hydrophiloides	Sweet-marsh Butterweed	Red	Vascular plant
Solidago nemoralis ssp. *decemflora*	Field Goldenrod	Blue	Vascular plant
Sphenopholis intermedia	Slender Wedgegrass	Blue	Vascular plant
Stellaria obtusa	Blunt-sepaled Starwort	Blue	Vascular plant
Thermopsis rhombifolia	Prairie Golden Bean	Red	Vascular plant
Torreyochloa pallida	Fernald's False Manna	Red	Vascular plant
Barbula convoluta var. *eustegia*	No common name	Red	Moss

Scientific Name	Common Name	BC List	Comments
Bartramia halleriana	Haller's Apple Moss	Red	Moss; SARA Schedule 1 - Threatened
Brachythecium holzingeri	No common name	Blue	Moss
Campylium calcareum	No common name	Red	Moss
Campylium radicale	No common name	Blue	Moss
Encalypta mutica	No common name	Blue	Moss
Entosthodon fascicularis	Banded Cord-moss	Blue	Moss; SARA Schedule 1 – Special Concern
Grimmia mollis	No common name	Blue	Moss
Hygrohypnum alpinum	No common name	Blue	Moss
Hygrohypnum norvegicum	No common name	Red	Moss
Oreas martiana	No common name	Red	Moss
Orthotrichum pallens	No common name	Blue	Moss
Philonotis marchica	No common name	Blue	Moss
Philonotis yezoana	No common name	Blue	Moss
Platyhypnidium riparioides	No common name	Blue	Moss
Pohlia elongata	No common name	Blue	Moss
Pylaisia intricata	No common name	Red	Moss
Rhodobryum roseum	No common name	Blue	Moss
Scouleria marginata	Margined Streamside Moss	Red	Moss; SARA Schedule 1 - Endangered
Seligeria tristichoides	No common name	Blue	Moss
Sphagnum jensenii	No common name	Red	Moss
Sphagnum wulfianum	No common name	Blue	Moss
Tortula obtusifolia	No common name	Blue	Moss
Ulota curvifolia	No common name	Blue	Moss
Warnstorfia tundrae	No common name	Red	Moss

APPENDIX 2

Bird Species Expected to Occur in the Vicinity of the Study Area
(Bird Studies Canada 2014). Excludes Non-Native Species and Species with a Probability of Observation <2%.

Bird Species Expected to Occur in the Vicinity of the Study Area (Bird Studies Canada 2014). Excludes Non-Native Species and Species with a Probability of Observation <2%.

Species	English Name	Scientific Name	BC List	Identified Wildlife	SARA
Canada Goose	Canada Goose	*Branta canadensis*	Yellow	-	-
Wood Duck	Wood Duck	*Aix sponsa*	Yellow	-	-
Gadwall	Gadwall	*Anas strepera*	Yellow	-	-
American Wigeon	American Wigeon	*Anas americana*	Yellow	-	-
Mallard	Mallard	*Anas platyrhynchos*	Yellow	-	-
Blue-winged Teal	Blue-winged Teal	*Anas discors*	Yellow	-	-
Cinnamon Teal	Cinnamon Teal	*Anas cyanoptera*	Yellow	-	-
Northern Shoveler	Northern Shoveler	*Anas clypeata*	Yellow	-	-
Northern Pintail	Northern Pintail	*Anas acuta*	Yellow	-	-
Green-winged Teal	Green-winged Teal	*Anas crecca*	Yellow	-	-
Canvasback	Canvasback	*Aythya valisineria*	Yellow	-	-
Redhead	Redhead	*Aythya americana*	Yellow	-	-
Ring-necked Duck	Ring-necked Duck	*Aythya collaris*	Yellow	-	-
Lesser Scaup	Lesser Scaup	*Aythya affinis*	Yellow	-	-
Bufflehead	Bufflehead	*Bucephala albeola*	Yellow	-	-
Common Goldeneye	Common Goldeneye	*Bucephala clangula*	Yellow	-	-
Barrow's Goldeneye	Barrow's Goldeneye	*Bucephala islandica*	Yellow	-	-
Hooded Merganser	Hooded Merganser	*Lophodytes cucullatus*	Yellow	-	-
Common Merganser	Common Merganser	*Mergus merganser*	Yellow	-	-
Ruddy Duck	Ruddy Duck	*Oxyura jamaicensis*	Yellow	-	-
Ruffed Grouse	Ruffed Grouse	*Bonasa umbellus*	Yellow	-	-
Spruce Grouse	Spruce Grouse	*Falcipennis canadensis*	Yellow	-	-
Dusky Grouse	Dusky Grouse	*Dendragapus obscurus*	Yellow	-	-
Sharp-tailed Grouse	Sharp-tailed Grouse	*Tympanuchus phasianellus*	Yellow	-	-
Common Loon	Common Loon	*Gavia immer*	Yellow	-	-
Pied-billed Grebe	Pied-billed Grebe	*Podilymbus podiceps*	Yellow	-	-

Species	English Name	Scientific Name	BC List	Identified Wildlife	SARA
Horned Grebe	Horned Grebe	*Podiceps auritus*	Yellow	-	-
Red-necked Grebe	Red-necked Grebe	*Podiceps grisegena*	Yellow	-	-
Eared Grebe	Eared Grebe	*Podiceps nigricollis*	Yellow	-	-
American Bittern	American Bittern	*Botaurus lentiginosus*	Blue	-	-
Great Blue Heron	Great Blue Heron	*Ardea herodias herodias*	Blue	-	-
Turkey Vulture	Turkey Vulture	*Cathartes aura*	Yellow	-	-
Osprey	Osprey	*Pandion haliaetus*	Yellow	-	-
Bald Eagle	Bald Eagle	*Haliaeetus leucocephalus*	Yellow	-	-
Northern Harrier	Northern Harrier	*Circus cyaneus*	Yellow	-	-
Sharp-shinned Hawk	Sharp-shinned Hawk	*Accipiter striatus*	Yellow	-	-
Cooper's Hawk	Cooper's Hawk	*Accipiter cooperii*	Yellow	-	-
Northern Goshawk	Northern Goshawk	*Accipiter gentilis*	Yellow	-	-
Red-tailed Hawk	Red-tailed Hawk	*Buteo jamaicensis*	Yellow	-	-
Golden Eagle	Golden Eagle	*Aquila chrysaetos*	Yellow	-	-
American Kestrel	American Kestrel	*Falco sparverius*	Yellow	-	-
Merlin	Merlin	*Falco columbarius*	Yellow	-	-
Peregrine Falcon	Peregrine Falcon	*Falco peregrinus anatum*	Red	-	1-SC
Virginia Rail	Virginia Rail	*Rallus limicola*	Yellow	-	-
Sora	Sora	*Porzana carolina*	Yellow	-	-
American Coot	American Coot	*Fulica americana*	Yellow	-	-
Sandhill Crane	Sandhill Crane	*Grus canadensis*	Yellow	Yes	-
Killdeer	Killdeer	*Charadrius vociferus*	Yellow	-	-
Spotted Sandpiper	Spotted Sandpiper	*Actitis macularius*	Yellow	-	-
Solitary Sandpiper	Solitary Sandpiper	*Tringa solitaria*	Yellow	-	-
Greater Yellowlegs	Greater Yellowlegs	*Tringa melanoleuca*	Yellow	-	-
Long-billed Curlew	Long-billed Curlew	*Numenius americanus*	Blue	Yes	1-SC

Species	English Name	Scientific Name	BC List	Identified Wildlife	SARA
Wilson's Snipe	Wilson's Snipe	*Gallinago delicata*	Yellow	-	-
Wilson's Phalarope	Wilson's Phalarope	*Phalaropus tricolor*	Yellow	-	-
Bonaparte's Gull	Bonaparte's Gull	*Chroicocephalus philadelphia*	Yellow	-	-
Ring-billed Gull	Ring-billed Gull	*Larus delawarensis*	Yellow	-	-
Herring Gull	Herring Gull	*Larus argentatus*	Yellow	-	-
Black Tern	Black Tern	*Chlidonias niger*	Yellow	-	-
Mourning Dove	Mourning Dove	*Zenaida macroura*	Yellow	-	-
Flammulated Owl	Flammulated Owl	*Psiloscops flammeolus*	Blue	Yes	1-SC
Great Horned Owl	Great Horned Owl	*Bubo virginianus*	Yellow	-	-
Northern Pygmy-Owl	Northern Pygmy-Owl	*Glaucidium gnoma*	Yellow	-	-
Barred Owl	Barred Owl	*Strix varia*	Yellow	-	-
Great Gray Owl	Great Gray Owl	*Strix nebulosa*	Yellow	-	-
Northern Saw-whet Owl	Northern Saw-whet Owl	*Aegolius acadicus*	Yellow	-	-
Common Nighthawk	Common Nighthawk	*Chordeiles minor*	Yellow	-	1-T
Vaux's Swift	Vaux's Swift	*Chaetura vauxi*	Yellow	-	-
White-throated Swift	White-throated Swift	*Aeronautes saxatalis*	Yellow	-	-
Calliope Hummingbird	Calliope Hummingbird	*Selasphorus calliope*	Yellow	-	-
Rufous Hummingbird	Rufous Hummingbird	*Selasphorus rufus*	Yellow	-	-
Belted Kingfisher	Belted Kingfisher	*Megaceryle alcyon*	Yellow	-	-
Lewis's Woodpecker	Lewis's Woodpecker	*Melanerpes lewis*	Red	Yes	1-T
Red-naped Sapsucker	Red-naped Sapsucker	*Sphyrapicus nuchalis*	Yellow	-	-
Red-breasted Sapsucker	Red-breasted Sapsucker	*Sphyrapicus ruber*	Yellow	-	-
Downy Woodpecker	Downy Woodpecker	*Picoides pubescens*	Yellow	-	-
Hairy Woodpecker	Hairy Woodpecker	*Picoides villosus*	Yellow	-	-

Species	English Name	Scientific Name	BC List	Identified Wildlife	SARA
American Three-toed Woodpecker	American Three-toed Woodpecker	*Picoides dorsalis*	Yellow	-	-
Black-backed Woodpecker	Black-backed Woodpecker	*Picoides arcticus*	Yellow	-	-
Northern Flicker	Northern Flicker	*Colaptes auratus*	Yellow	-	-
Pileated Woodpecker	Pileated Woodpecker	*Dryocopus pileatus*	Yellow	-	-
Olive-sided Flycatcher	Olive-sided Flycatcher	*Contopus cooperi*	Blue	-	1-T
Western Wood-Pewee	Western Wood-Pewee	*Contopus sordidulus*	Yellow	-	-
Alder Flycatcher	Alder Flycatcher	*Empidonax alnorum*	Yellow	-	-
Willow Flycatcher	Willow Flycatcher	*Empidonax traillii*	Yellow	-	-
Least Flycatcher	Least Flycatcher	*Empidonax minimus*	Yellow	-	-
Hammond's Flycatcher	Hammond's Flycatcher	*Empidonax hammondii*	Yellow	-	-

APPENDIX 3

Wildlife Species Accounts

WILDLIFE SPECIES ACCOUNT: MULE DEER

This species account has been adapted from the mule deer accounts provided in:

Geowest Environmental Consultants Ltd. and Keystone Wildlife Research Ltd. 2001. Terrestrial Ecosystem Mapping for the East Cariboo Area, Williams Lake, British Columbia Volume II: Wildlife Species Profiles and Habitat Suitability Assessment. Report to BC Ministry of Environment, Lands and Parks, Williams Lake.

and

JMJ Holdings Inc., BA Sinclair, and G. Burns. 2000. Chilcotin West IFPA Wildlife Species Accounts.

Species Data

Species Name: Mule Deer

Scientific Name: *Odocoileus hemionus*

Species Code: M-ODHE

Provincial Status: Yellow-Listed (not at risk)

Identified Wildlife Status: No

COSEWIC Status: Not At Risk

Project Data

Ecoprovince: Southern Interior Mountains

Ecoregion: Columbia Highlands

Ecosection: Quesnel Highland

Biogeoclimatic Subzone Variants: ICHmk3, ICHwk2

Map Scale: 1:50,000

INTRODUCTION

The mule deer is one of the most abundant ungulates in the province, and is prized as a game animal. There are three subspecies in the province; the Columbian black-tailed deer (Odocoileus hemionus columbianus), which inhabits Vancouver Island and the southern coast, the Sitka black-tailed deer (Odocoileus hemionus sitkensis) found on the north coast of the province, and the mule deer (Odocoileus hemionus hemionus) which is found in the interior of the province, including the Mount Polley area (Shackleton 2013).

DISTRIBUTION

Mule deer may be found in all biogeoclimatic zones (Stevens 1995) but are rare in the north half of the province. Mule deer have difficulty moving through snow deeper than 30 cm (MELP 2015). Therefore, mule deer are expected to be found throughout the Mount Polley study area during the growing season but are not expected to winter there due to deep snow. No deer winter ranges have been mapped by the province near the Mount Polley Mine. Only growing season habitat is considered in this species account.

Distribution in the Project Area

Densities of mule deer within the project area are unknown. Deer are widely dispersed in summer and probably occur in low numbers (<1/ km2) in the Mount Polley area. Because of their secretive behaviour, habitat use by does with young is most difficult to document.

ECOLOGY AND KEY HABITAT REQUIREMENTS

Mule deer rut during mid-October and early December (Stevens and Lofts 1988). Fawns are born in June after a gestation of approximately 210 days (Banfield 1981). Optimum fawning habitat has a dense understory of low shrubs or small trees from 0.6 - 1.8 m tall and a tree overstory of approximately 50% crown closure. Good fawning habitat is in close proximity to suitable foraging areas (Stevens and Lofts 1988).

Average home range for mule deer varies widely between individuals, sexes, and habitat occupied. Bucks generally use larger areas than the does.

Feeding

Mule deer are considered generalists and are capable of digesting a wide variety of plants. They are mainly browsers of shrubby vegetation, but they will also eat forbs and grasses, especially during the spring season. Forage preferences are determined by a combination of seasonal variations in forage digestibility and protein content, and by the nutritional requirements of the animals. Summer forage plants are listed in Table 1.

Table 1: Important Growing-Season Forage Plantsfor Mule Deer in the Central Interior of British Columbia.

Lichens	*Bryoria* spp. *Alectoria* spp.

During the growing season, mule deer will forage in a variety of habitats ranging from grassy openings to old growth forest. During the spring, areas of early green-up are important for feeding. These habitats occur at low elevations on moderate to steep, south and west-facing slopes.

Summer habitat consists of areas with a suitable mix of young to old forest areas, with an adequate supply of forage and cover elements. Few deer are expected to use very dense forest where little light penetrates the canopy or ecosystem units with limited understory growth. Lush, moist sites are preferred. Foods used in the growing season consist of a wide variety of herbs, grasses and shrubs. Food is considered to be superabundant and is not limiting, especially in the moist forest types favoured by deer in the growing season.

Security and Thermal Habitat

Growing season thermal habitat (shade) is used to prevent overheating during hot summer months. Any habitat with shrubs or trees in structural stage 3 or older can provide adequate shade but cool aspects and riparian areas are likely to provide the coolest sites. Canopy closure ranges of 26-35% will provide adequate thermal cover during hot weather (Demarchi and Bunnell 1993).

The most effective security cover for mule deer hides 90% of the animal at a distance of 60 m or less, and security patches should to be 180 m or more in diameter (Nyberg & Janz 1990). Sufficient hiding cover is provided by understory and dense low branches 1-2 m in height. In general, old growth forests with a patchy conifer understory and most well-stocked stands of young trees with live branches will satisfy security cover requirements. Areas of steep broken terrain can also be used as security habitat. (Nyberg & Janz 1990). Riparian areas with dense shrubby cover are used for fawning in the spring. At a landscape scale, Robinson et al. (2006) found that there was a strong selection of spruce/fir forests by both sexes, both preferred older stands, and both avoided stands with >55% canopy closure during summer.

Migration Habitat

Mule deer often use high-elevation forests in summer and migrate to lower elevation drier subzones and warm aspect slopes for the winter (Hayden et al. 2008; D'Eon and Serrouya 2005). Most animals move off winter ranges in late April or May and move directly to summering areas which they occupy from late May through September. Some does move to spring ranges in April or early May, remaining there until late May or early June. They move to summer ranges just before fawning. Spring ranges may be well removed from winter or summer ranges.

Limiting Habitat

Mule deer likely use the project area in the spring, summer, and early fall (growing season). Male and female deer exhibit similar habitat use except in summer when females with young choose more densely forested sites than males do. Ground cover, sufficiently tall and dense to conceal bedded fawns, is believed to be a key habitat component. Visual cover for adult deer and wet ground, which may hindered scent tracking of adults by predators, is also considered important.

Birthing areas may be the most important component of habitats used by deer in the growing season; however, since summer ranges are very small, all life requisites must be found within small areas (8 km^2). Based on results of other studies (Simpson and Gyug 1991), most sites (60%) where fawns were born were forest and the rest were in sedge meadows or riparian areas. However, fawning habitats cannot be considered independently of the needs of the adults so they have been rated as an essential component of mule deer summer range.

SEASONS OF USE

For the purposes of this species account, the definition of the growing season (spring, summer, and fall) is based on that defined by RIC (1999). Table 2 presents the seasonal divisions for mule deer in the Southern Interior Mountains.

Table 2: Seasons of Use for Mule Deer in the Southern Interior Mountains (RIC 1999)

Month	Season
November-April	Winter
May- June	Growing Season (Spring)
July-August	Growing Season (Summer)
September-October	Growing Season (Fall)

HABITAT USE AND ECOSYSTEM ATTRIBUTES

Characteristics of expected high-value habitats for mule deer during the growing season are summarized in Table 3.

Table 3: Key Habitat Attributes for Mule Deer in the Growing Season

Secondary Life Requisite	Primary Life Requisite	Attributes Required	Structural Stage
Living	Security/thermal cover (ST)	dense understory of vegetation >1.5 m tall	3b to 7
	Feeding (FD)	mosaic of small shrubby or grassy openings with lush forage plants, interspersed with cover; herb wetlands	2 to 7

Provincial Benchmark

The provincial benchmark for mule deer growing season habitat is the ESSFdk Subalpine Meadow in the Southern Interior Mountains ecoprovince (RIC 1999). The subzones within the study area are not known to be particularly productive for deer during the growing season. The maximum rating applied will be Moderately High.

Rating Scheme

A six-class rating scheme (Table 4) was used to rate mule deer habitat. Mule deer habitats were rated for Living/Growing/Feeding (LI/G/FD), and Living/Growing/Security-Thermal (LI/G/ST).

Table 4: Six and Four-Class Rating Schemes Used for Habitat Ratings (RIC 1999)

% of Provincial Best*	Substantial Knowledge of Habitat Use (6-class)		Intermediate Knowledge of Habitat Use (4-class)	
	Rating	Code	Rating	Code
100 - 76%	High	1	High	H
75 - 51%	Moderately High	2	Moderate	M
50 - 26%	Moderate	3		
25 - 6%	Low	4	Low	L
5 - 1%	Very Low	5		
0%	Nil	6	Nil	N

*"Provincial Best" is the provincial benchmark habitat for a species against which all other habitats are compared.

Rating Assumptions

This habitat rating scheme assumes that security cover used by mule deer in the early-spring season is not appreciably different from that used during the remainder of the growing season. Security habitat used during the growing season is assumed to also provide adequate thermal habitat during the growing season. Riparian forests and wetlands provide the best reproductive habitats for mule deer as noted in studies in other areas.

1) Cutblocks or other openings in structural stage 3 should be rated up to 2 for feeding and up to 3 for cover.

2) Riparian forest and moist to mesic forest in structural stages 5-7 should be rated up to 2 for feeding and cover.

3) Drier than mesic forest in structural stages 5-7 should be rated up to 3 for feeding and cover.

4) Wetlands are rated up to 3 for feeding and 4 for cover. Shrub floodplains should be rated up to 2 for feeding and 4 for cover.

A summary of the ratings assigned to ecosystems within the study area is provided below (Table 5).

WILDLIFE SPECIES ACCOUNT: FISHER

This model has been updated and revised for the study area and is based upon an earlier account in:

EBA Engineering Consultants Ltd. 2002. Ecosystem Mapping With Wildlife Interpretations to Support Oil and Gas Pre-Tenure Planning in the Muskwa-Kechika Management Area. Report to B.C. Ministry of Energy & Mines – Petroleum Lands Branch, Fort St. John, BC.

Species Data

Species Name: Fisher

Scientific Name*: Pekania pennanti*

Species Code: M-PEPE

Provincial Status: Blue-Listed

Identified Wildlife Status: No

COSEWIC Status: Not At Risk

Project Data

Ecoprovince: Southern Interior Mountains

Ecoregion: Columbia Highlands

Ecosection: Quesnel Highland

Biogeoclimatic Subzone Variants: ICHmk3, ICHwk2

Map Scale: 1:50,000

INTRODUCTION

The fisher is a large mustelid (weasel) that inhabits forested habitat across the province. Fishers are valued as furbearers. They are generally solitary, and feed mainly on small mammals and birds as well as vegetation such as berries. Fishers are vulnerable to overharvest and to loss of forest habitat and there are estimated to be fewer than 3800 in the province (BC Conservation Data Centre 2015).

DISTRIBUTION

Fishers are distributed throughout the forested areas of North America and most of British Columbia. Fishers are found throughout mainland British Columbia north of Kamloops although they are rare in coastal ecosystems (Nagorsen 1990; Weir and Almuedo 2010).

Distribution in the Project Area

Fishers are not common within the ICH biogeoclimatic zone (Weir and Almuedo 2010). Their presence near Mount Polley has not been confirmed but their provincial range does include the study area.

ECOLOGY AND KEY HABITAT REQUIREMENTS

General

Optimal habitats for fishers are considered mature coniferous forests and mixed conifer/hardwood stands, mostly in areas of continuous overhead cover (Allen 1983; Powell 1992; Krohn et al. 1996; Weir and Almuedo 2010). Landscape-scale fisher habitat requirements are not well understood, however their preference for diverse habitats created by multi-aged stands containing wetland or riparian habitat and their requirement for continuous overhead cover is well documented (Banci 1989; Powell and Zielinski 1994). Small forest openings created by fire and wind-throw are a natural component of fisher habitat although large, non-forested areas, such as those created by clear-cut logging, are beyond the scale of natural disturbances. Other important landscape attributes, such as stand size and shape and use of corridors, are not known (Krohn et al. 1996).

Throughout their range, fishers exhibit a strong preference for forests with high canopy closure and avoid areas with low overhead cover. In the Pacific States and the Rocky Mountains, fishers appear to use riparian areas disproportionately more than their occurrence (Powell 1992; Powell and Zielinski 1994; Jones and Garton 1994). These areas likely provide several functions including high prey abundance, abundant snags for dens/resting sites and high canopy closure which provides snow interception.

Forest structure is likely more important to fisher than specific forest types. Vertical and horizontal complexity, created by a diversity of tree sizes and shapes, light gaps, dead and downed wood and layers of overhead cover, provide good prey habitat, dens and resting sites (Powell and Zielinski 1994). Fishers infrequently use large forest openings, open hardwood forests, recent clear-cuts, grasslands, areas above timberline and other non-forested areas (Powell and Zielinski 1994). In fact, Powell (1992) states that fisher have avoided open areas 25 m across or less in the American Midwest.

Some authors have shown differences in fisher winter and summer habitat. Jones and Garton (1994), studying in the Rocky Mountains of north-central Idaho, found that fishers preferred mature and old-growth forests during summer but used young forests in winter. They hypothesized that the shift to younger stages may be due to a shift in prey use, specializing more towards snowshoe hare. Kelly (1977, as cited in Powell 1992) also found changes in seasonal habitat use. Banci (1989) reported that fishers in BC do not use different elevations in different seasons.

Fishers can travel long distances during short periods of time, about 5-6 km per day (reviewed by Powell and Zielinski 1994). Home ranges are generally exclusive by sex. Males generally have larger territories than females – an adult male's home range is generally >100 km^2 and may overlap those of several females. A female's home range is usually >25 km^2 (Weir and Almuedo 2010). Weir and Corbould (2008) noted that home ranges of fishers in the Williston region were typically larger in winter than non-winter.

Fishers have been found to be confined to or have greater density in areas with low snow accumulation (Powell 1992). Travel in deep snow is energetically costly and, compared to marten, they are less able to access the sub-nivean spaces because of their larger body size. Where snow is deep and frequent, fishers should be expected to be either absent or occur where dense overhead cover intercepts snowfall (Krohn *et al*. 1996).

Feeding Habitat

Optimum foraging habitat for fishers is provided by a mosaic of different forest types in various structural stages, together with forest floor structural complexity, which provide habitat niches for a diversity of prey species. Fishers may forage in different habitats from the ones they use for resting and denning therefore, a complete description of fisher habitat requirements must consider both foraging and resting and denning needs.Fishers will forage in areas that do not provide good year-round cover, such as younger forests and regenerating clear-cuts.

Fishers are opportunistic feeders (Banci 1989) and their prey may occur in a variety of forest types and seral stages (Powell and Zielinski 1994). Primary prey species are associated with abundant CWD and understory shrub cover. Snowshoe hares (*Lepus americanus*) and rodents form the bulk of their diet but they will eat virtually any vertebrate that they are capable of killing (Forsyth 1985; BCMWLAP 2004). Other common food items include birds, fish, snakes, toads, insects, fruit, seeds, berries, fern tips and carrion (Forsyth 1985). Habitats with high small mammal diversity, such as riparian areas, wetlands and mixed conifer-hardwood forest types, are most preferred for foraging (Kelly 1977 as cited in Powell 1992).

Foraging habitat for fishers in winter is much the same as in summer. However, in winter fishers, because of their large body size, are restricted to hunting on the snow surface (Powell 1982). Therefore, structurally complex debris (CWD), which provides subnivean access, may not be required as foraging habitat. Deep winter snow may limit the distribution of fishers (Aubry and Houston 1992). Weir and Corbould (2008) found the likelihood of activity of fishers increased with fresh snowfalls of ≥5 cm during winter.

Analysis of stomach contents by Weir et al. (2005) indicated that prey during winter is varied; however, snowshoe hares, red squirrels, and southern red-backed voles were the most common prey observed. It was also noted that in winter, females tended to exploit small mammals more than did males (Weir et al. 2005).

Thermal-Security Habitat

Security habitat conceals fishers from larger predators and modifies extremes in climate thus assisting them in maintaining a constant body temperature. Thermal habitat is more critical for fishers in winter when they may be nutritionally stressed and need to minimize energy expenditures. Security is provided by continuous overhead forest cover and in structures associated with late-successional forests. Fishers avoid wetlands, cutblocks and other open areas (Weir and Almuedo 2010).

Resting and denning sites tend to occur in structures associated with late-successional forests (Powell and Zielinski 1994; Jones and Garton 1994). This includes large trees, snags and logs greater than 55 cm dbh on average (Powell and Zielinski 1994). Weir and Corbould (2008) found that fishers rested most frequently on branch rest structures (57%); however, were more likely to use cavity rest sites than branch sites near the centre of their home ranges and were more likely to use coarse woody debris (CWD) when ambient temperatures were < -11°C. Fishers will rest in ground dens among coarse woody debris and slash piles during periods of low temperatures (below –20° C). Weir (1995) reported a greater-than-expected winter use by fishers of habitats with >50 m^3/ha of large debris (more than 20 cm diameter).

Corbould (2008) found that fishers were highly selective for patches used for resting, selecting patches of habitat with higher densities of trees with rust brooms. Other resting sites include piles of coarse woody debris, squirrel middens, tree cavities and squirrel nests. Rest sites are generally in the trees with the largest diameter available and those with the most rust brooms (Weir 1995).

Reproducing Habitat

Fishers mate in early April, and females give birth in dens in tree cavities (BC MWLAP 2004). Maternity denning habitat is the limiting habitat for fishers. This habitat includes trees with large cavities, which are generally found in late-successional forests. Maternal den site requisites are believed to be more stringent than those used for resting (Weir 1995). Natal dens are located most often in cavities of large trees and are situated 7 to 12 m above the ground (Banci 1989).

Dens are usually in live trees that have some defect (fire damage, cracks, heart rot, branch scars) that permits access to the interior of the tree. Suitable maternal den trees include black cottonwood/poplar at least 50 cm dbh, trembling aspen at least 40 cm dbh, lodgepole pine at least 35 cm dbh, and Douglas-fir at least 60 cm dbh (Weir and Almuedo 2010). In the Sub-Boreal Spruce zone, black cottonwood trees were the only trees observed to be used as reproductive dens, with cavities in large-diameter cottonwoods appearing to be a critical habitat element (Weir and Corbould 2008). Weir and Corbould (2008) concluded that these provided features and conditions beneficial to denning, including protection from weather, thermally advantageous, protection/concealment from potential hazards, and an elevated vantage point.

Females may re-use the same den tree or succession of den trees over a number of years (Weir and Almuedo 2010). Weir and Corbould (2008) observed females using between 1 and 3 trees as reproductive dens during the rearing period. It was also found that all female fishers that whelped more than once during the study period re-used den sites (Weir and Corbould 2008). At the stand level, suitable maternity den trees are most likely to be found in moist or riparian forests in mature and old structural stages.

SEASONS OF USE

For the purposes of this model, the definition of the seasons is based on that defined by RIC (1999). Table 2 presents the seasonal divisions for fishers in the Southern Interior Mountains.

Table 2: Seasons of use for fishers in the Southern Interior Mountains (RIC 1999)

Month	Season
November-April	Winter
May- June	Growing Season (Spring)
July-August	Growing Season (Summer)
September-October	Growing Season (Fall)

HABITAT USE AND ECOSYSTEM ATTRIBUTES

Ratings will be provided for Reproducing-birthing during the spring and summer. Characteristics of expected high-value habitats for reproducing-birthing habitat for fishers are summarized in Table 3.

Table 3: Key Reproducing Habitat Attributes for Fishers During Spring and Summer

Life Requisite	Primary Life Requisite	Attributes Required	Structural Stage
Reproducing – Birthing (RB)	Security /thermal cover (SH)	Presence of large-diameter *Populus*, most likely found in riparian or moist forest stands	6 to 7

Ratings

Habitat ratings were generated using the four-class rating scheme (Table 4).

Table 4: Six and Four-Class Rating Schemes Used for Habitat Ratings (RIC 1999)

% of Provincial Best*	Substantial Knowledge of Habitat Use (6-class)		Intermediate Knowledge of Habitat Use (4-class)	
	Rating	Code	Rating	Code
100 - 76%	**High**	**1**	**High**	**H**
75 - 51%	**Moderately High**	**2**	**Moderate**	**M**
50 - 26%	**Moderate**	**3**		
25 - 6%	**Low**	**4**	**Low**	**L**
5 - 1%	**Very Low**	**5**		
0%	**Nil**	**6**	**Nil**	**N**

*”Provincial Best” is the provincial benchmark habitat for a species against which all other habitats are compared.

Provincial Benchmark

The highest densities of fishers in BC have been recorded in the Sub-boreal Spruce zone in northeastern BC (Weir and Corbould 2006), which is assumed to be the provincial benchmark. The ICH is not known to be a zone with high densities of fishers. The maximum rating assigned (after adjustments) will be Moderate.

Assumptions

Forested habitats in structural stages 6 (mature forest) and 7 (old forest) represent the most likely forest types to provide suitable den trees for birthing and rearing young. These ecosystems are rated up to Low. All other structural stages, and nonvegetated and anthropogenic units, are rated Nil. A summary of the ratings applied to the ecosystems within the study area before adjustments is presented below (Table 5).

WILDLIFE SPECIES ACCOUNT: MYOTIS BATS

Species Data

Species Name: Little brown myotis; northern myotis

Scientific Name*: Myotis lucifugus*; *M. septentrionalis*

Species Code: M-MYOT

Provincial Status: Blue-Listed (northern myotis); Yellow-listed (little brown myotis)

Identified Wildlife Status: No

COSEWIC Status: Endangered

Project Data

Ecoprovince: Southern Interior Mountains

Ecoregion: Columbia Highlands

Ecosection: Quesnel Highland

Biogeoclimatic Subzone Variants: ICHmk3, ICHwk2

Map Scale: 1:50,000

INTRODUCTION

The little brown myotis and northern myotis are small brown bats that feed on aerial invertebrates. Both species are threatened by the fungal disease known as white-nose syndrome, which affects bats as they hibernate during the winter. White-nose syndrome is not known to be present in British Columbia but the disease is currently present in Ontario and is spreading westward. The little brown myotis and northern myotis have recently been listed as Endangered under SARA due to catastrophic die-offs of these species from white-nose syndrome in eastern North America (Government of Canada 2014).

DISTRIBUTION

The little brown myotis occupies a wide variety of habitats (BC Conservation Data Centre 2015a; Nagorsen and Brigham 1993) and is well-distributed across North America (COSEWIC 2013). It is found across the province of BC (BC Ministry of Environment 2008a).

The range of the northern myotis extends from the Atlantic provinces across eastern North America as far west as eastern BC (COSEWIC 2013). The northern myotis is associated with boreal forests in BC (Nagorsen and Brigham 1993) and is found from Revelstoke north to the Yukon border (BC Ministry of Environment. 2008b).

Distribution in the Project Area

The presence of the little brown myotis and northern myotis in the vicinity of Mount Polley has not been confirmed but the provincial range of both species does include the study area. Little brown myotis and one individual field-identified as a northern myotis were captured in 2012 near Spanish Lake (approximately 11 km northeast of the mouth of Hazeltine Creek) during surveys for Spanish Mountain Gold (survey data file at http://a100.gov.bc.ca/pub/siwe/details.do?id=5044).

ECOLOGY AND KEY HABITAT REQUIREMENTS

Both little brown myotis and northern myotis hibernate during the winter. Little brown myotis may travel up to 200 km to hibernacula in abandoned mines (Nagorsen and Brigham 1993). Hibernacula of northern myotis have not been confirmed in BC but this species hibernates in tunnels, caves and mines in other locations (COSEWIC 2013).

Myotis bats leave their hibernacula in spring when flying insects are once again available. Female northern myotis and little brown myotis give birth to a single pup annually, usually in June or July (B.C. Conservation Data Centre 2015a, b). Multiple females rear their young in communal maternity roosts, which are often re-used year to year. The pups fledge in late summer and are weaned at approximately 26 days of age (Burnett and Kunz 1982 in COSEWIC 2013). Mating takes place in the fall before or during hibernation. The females store the sperm over the winter before becoming pregnant in early spring (B.C. Conservation Data Centre 2015a, b).

Feeding

Little brown myotis emerge from their roosts at dusk and forage for insects, which they capture in flight. Primary prey species include midges, caddisflies and mayflies (Nagorsen and Brigham 1993) but many types of insect are taken as long as they are the appropriate size. Northern myotis in the eastern United States consumed primarily Lepidoptera (moths) and Coleoptera (beetles) (Dodd et al. 2012).

Little brown myotis and northern myotis forage over waterbodies, rivers, forest openings and along edges and forest trails (COSEWIC 2013). Northern myotis prefer interior forest (B.C. Conservation Data Centre 2015b) and avoid flying through open, nonforested areas (Alberta Sustainable Resource Development and Alberta Conservation Association 2009).

Thermal-Security

Maternity roost sites and hibernacula are thought to be the limiting habitat features for both species (Barclay and Brigham 1996 in COSEWIC 2013; Norquay et al. 2013 in COSEWIC 2013). Females may use several different roost sites while pregnant and nursing (Barclay and Kurta 2007). Little brown myotis day-roost in tree cavities, in rock crevices, in buildings, and in caves (Nagorsen and Brigham 1993). Warm roost sites are preferred by pregnant and nursing females in order to speed development of their pups (Alberta Sustainable Resource Development and Alberta Conservation Association 2009). Little brown myotis maternity roosts have been found in buildings but northern myotis have not been documented using buildings in BC (COSEWIC 2013; Nagorsen and Brigham 1993).

Northern myotis and little brown myotis in northeastern British Columbia were found to roost primarily in mature stands of deciduous trees (trembling aspen and balsam poplar) where large snags were present in a variety of age classes (Vonhof and Wilkinson 2000; Keystone Wildlife Research Ltd. 2009). Reproductive female northern myotis and little brown myotis typically roost in colonies while non-reproductive females and males usually roost singly (Nagorsen and Brigham 1993; Vonhof and Wilkinson 2000). Typical roost microsites include cavities created by rot or by woodpeckers, under loose bark, or within crevices or splits on the trunk (Vonhof and Wilkinson 2000). In general, myotis roosting habitat tends to be composed of older forests with tall, large-diameter snags or defect trees in early stages of decay, that are in relatively open sites where they are warmed by the sun and there is a clear flight path (B.C. Conservation Data Centre 2015a, b). Older forest stands tend to have greater numbers of potentially suitable trees and snags (Alberta Sustainable Resource Development and Alberta Conservation Association 2009; COSEWIC 2013).

SEASONS OF USE

For the purposes of this model, the definition of the seasons is based on that defined by RIC (1999). Table 2 presents the seasonal divisions for *Myotis* in the Southern Interior Mountains.

Table 2: Seasons of Use for *Myotis* in the Southern Interior Mountains (RIC 1999)

Month	Season
November-April	Winter
May- June	Growing Season (Spring)
July-August	Growing Season (Summer)
September-October	Growing Season (Fall)

HABITAT USE AND ECOSYSTEM ATTRIBUTES

Ratings will be provided for Security-Thermal (roosting) habitat during the growing season. Characteristics of expected high-value roosting habitats for Myotis bats are summarized in Table 3.

Table 3: Key Roosting Habitat Attributes for Myotis During Spring and Summer

Life Requisite	Primary Life Requisite	Attributes Required	Structural Stage
Reproducing – Birthing (RB)	Security /thermal cover (ST)	Old or mature forest stands, presence of large-diameter *Populus*, or aspen, most likely found in riparian or moist ecosystem units	5 to 7

Ratings

Habitat ratings were generated using the four-class rating scheme (Table 4). The four classes used are High (H), Moderate (M), Low (L) and Nil (N).

Table 4: Six and Four-Class Rating Schemes Used for Habitat Ratings (RIC 1999)

% of Provincial Best*	Substantial Knowledge of Habitat Use (6-class)		Intermediate Knowledge of Habitat Use (4-class)	
	Rating	Code	Rating	Code
100 - 76%	High	1	High	H
75 - 51%	Moderately High	2	Moderate	M
50 - 26%	Moderate	3		
25 - 6%	Low	4	Low	L
5 - 1%	Very Low	5		
0%	Nil	6	Nil	N

*"Provincial Best" is the provincial benchmark habitat for a species against which all other habitats are compared.

Provincial Benchmark

There are no agreed-upon provincial benchmarks for bat habitats. High ratings are assumed possible in the study area. The maximum rating assigned (after adjustments) will be High.

Assumptions

Forested habitats in structural stages 6 (mature forest) and 7 (old forest) represent the most likely forest types to provide suitable roost trees for bats. These ecosystems are rated up to Moderate. Structural stages 3-5 are rated up to Low, and all vegetated habitats in structural stage 1-2 and all nonvegetated and anthropogenic units are rated Nil. A summary of the ratings applied to the ecosystems within the study area is presented below (Table 5).

Map Themes and Ratings Adjustments

The map theme that can be produced is Security-Thermal (roosting) habitat. Polygon suitability will be adjusted using information from the Vegetation Resources Inventory (VRI). Polygons with *Populus* sp. in structural stages 5-7 will be adjusted upwards by one ratings class for all ecosystems originally rated M or L (e.g., an L rating is adjusted to an M rating).

Summary

On August 4, 2014, a failure of the Tailings Storage Facility (TSF) dam (the event) and subsequent debris flow occurred at Mount Polley Mine near the Town of Likely, British Columbia. The purpose of this Quesnel and Polley Lakes Aquatic Productivity Impact Assessment (LAPIA) is to provide a preliminary characterization of potential changes in lake productivity as a result of the event. This report also addresses potential effects on Quesnel River.

This report provides a preliminary assessment of potential effects on the aquatic environment of the lakes and Quesnel River based on information available and understanding of the event at this time; however, this understanding is expected to increase as further studies are undertaken. The objective of this report was to address the potential effects on the overall aquatic productivity of Quesnel and Polley Lakes and Quesnel River as a result of the event. It was informed per Department of Fisheries and Oceans (DFO) guidance on assessing fisheries productivity to facilitate the efforts of the Habitat Remediation Working Group that has been established.

To facilitate the assessment of potential effects on productivity a conceptual ecological model was developed for fish-habitat-food interactions. These habitat and food requirements were grouped, resulting in three general assemblages applicable to a summer condition when the event occurred. The significance of the three assemblages is how potential stressors related to the event may affect lake productivity. The three fish-habitat-food assemblages and the preliminary potential for effects identified were as follows.

Littoral Zone and Benthic Habitats - Fish associated with the littoral zone and benthic habitats are oriented to the near-shore environment and feed largely on benthic prey (e.g., amphipods, larvae and pupae of aquatic insects such as chironomids), periphyton, or in some cases crustacean zooplankton in the water column. Fish in this group include early juvenile stages of salmon (*Oncorhynchus* spp.), Burbot (*Lota lota*), and Lake Whitefish (*Coregonus clupeaformis*) and are benthivores (i.e., their food comes from benthic substrates), and forage fish such as sucker, sculpin, chub, shiner and Northern Pikeminnow (*Ptychocheilus oregonensis*). The event resulted in the alteration of littoral habitat at the mouth of Hazeltine Creek, resulting in the displacement or potential (unconfirmed) loss of fish in the area. Debris was also deposited on the lakebed in the profundal area, which resulted in a change in the benthic habitat and a potential disruption in the benthic invertebrate community. The impact on the bed of Quesnel Lake continues to be studied. Although early sampling suggests that some recovery may have begun, benthos sampling subsequent to deposition and settling of the sediments is necessary to confirm if the impact is of a transient nature. Post-event toxicity testing indicated that Quesnel Lake water did not affect survival or growth of fish or growth of plant test species and geochemical evaluations carried out have found that the tailings will be chemically stable in the lakes and are not expected to leach.

Open-Water Habitat and Fish that Feed on Emerging Insects - Fish associated with open-water habitat and feed on emerging insects (e.g., chironomids) include Mountain Whitefish (*Prosopium williamsoni*) and smaller Rainbow Trout (*Oncorhynchus mykiss)*. Larger Rainbow Trout in Quesnel Lake may consume juvenile Sockeye Salmon (*O. nerka*) and Kokanee (*O. nerka*; freshwater variant). This assemblage also applies to Polley Lake, in which the main fish species is Rainbow Trout. Although early sampling suggests that some recovery may have begun, benthos sampling subsequent to deposition and settling of the sediments is necessary to confirm if the impact is of a transient nature. Post-event toxicity testing indicated that lake water did not affect survival or

growth of fish or growth of plant test species. In Polley Lake, Rainbow Trout size did not appear to change with condition factor of the trout being within the ranges measured in prior years; however, the event likely affected reproduction through the loss of eggs in the Upper Hazeltine Creek spawning habitat in 2014 and potentially through the loss of use of that habitat in 2015.

Open-Water Habitat and Fish that Feed on Crustacean Zooplankton - The assemblage of fish associated with open-water habitat and which feed on crustacean zooplankton consists of juvenile Sockeye Salmon and Kokanee. During the summer, this assemblage may also include Lake Trout. Post-event toxicity testing indicated that Quesnel Lake water did not affect survival or growth of fish, survival or growth of daphnid zooplankton, or growth of plant test species. The literature indicates that the direction of change in primary productivity as a result of introduction of suspended sediments to a lake depends on whether the phytoplankton are light limited or nutrient limited. The preliminary information available at this time suggest that there was an influx of phosphorus into Quesnel Lake and although changes in phytoplankton and zooplankton biomass were not observed, juvenile Sockeye Salmon collected west of Cariboo Island were larger than those from the lake east of Cariboo Island.

Quesnel River experienced several pulses of turbid water during transient seiche (internal lake wave) events and lake turnover. Post-event toxicity testing indicated that Quesnel River water did not affect survival or growth of fish, development of Rainbow Trout eggs through to alevins, survival or growth of daphnid zooplankton, or growth of plant test species. Richness and measures of diversity of the benthic invertebrate community in the river near the Town of Likely were similar to the reference locations as were the relative abundance of species sensitive to metals.

Some effects are duration dependent and additional data collection is presently underway that will further inform the understanding of the effect the event had on Quesnel and Polley Lakes and Quesnel River:

- MPMC commenced water quality and zooplankton sampling in May, 2015.
- The benthic invertebrate community in Quesnel and Polley Lakes will be sampled again in summer 2015 to evaluate the abundance and diversity of benthos in the disturbed areas of the lakebed.
- The disturbed area of the lakebeds will be monitored for habitat quality in summer 2015.

Finally, a human health and ecological risk assessment will be undertaken to evaluate the potential effects of the chemical parameters of concern on the lake environments. This will include an interpretation of fish tissue chemistry collected following the event.

Study Limitations

This report was prepared for the exclusive use of Mount Polley Mining Corporation (MPMC). The inferences concerning the data, site and receiving environment conditions contained in this report are based on information obtained during investigations conducted at the site by Golder, other consultants and MPMC, and are based solely on the condition of the site at the time of the site studies and subsequent investigations and remediation and other information obtained by Golder, as described in this report. Soil, surface water and groundwater conditions may vary with location, depth, time, sampling methodology, analytical techniques and other factors.

In evaluating the subject site and water quality data, Golder has relied in good faith on information provided. The factual data, interpretations and recommendations pertain to a specific project as described in this report, based on the information obtained during the assessment by Golder on the dates cited in the report, and are not applicable to any other project or site location. Golder accepts no responsibility for any deficiency or inaccuracy contained in this report as a result of reliance on the aforementioned information.

The findings and conclusions documented in this report have been prepared for the specific application to this project, and have been developed in a manner consistent with that level of care normally exercised by environmental professionals currently practising under similar conditions in the jurisdiction. Golder makes no other warranty, expressed or implied and assumes no liability with respect to the use of the information contained in this report at the subject site, or any other site, for other than its intended purpose.

Any use which a third party makes of this report, or any reliance on or decisions to be made based on it, are the responsibility of such third parties. Golder accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or action based on this report. All third parties relying on this report do so at their own risk. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely upon the electronic media versions of Golder's report or other work product. Golder is not responsible for any unauthorized use or modifications of this report.

MPMC may rely on the information contained in this report subject to the above limitations.

Golder makes no other representation whatsoever, including those concerning the legal significance of its findings, or as to other legal matters touched on in this report, including, but not limited to, ownership of any property, or the application of any law to the facts set forth herein.

If new information is discovered during future work, including excavations, sampling, soil boring, predictive geochemistry or other investigations, Golder should be requested to re-evaluate the conclusions of this report and to provide amendments, as required, prior to any reliance upon the information presented herein. The validity of this report is affected by any change of site conditions, purpose, development plans or significant delay from the date of this report in initiating or completing the project.

1.0 INTRODUCTION

1.1 Background

On August 4, 2014, a failure of the Tailings Storage Facility (TSF) dam (the event) and subsequent debris flow occurred at Imperial Metal's Mount Polley Mine (Figure 1). The purpose of this Quesnel and Polley Lakes Aquatic Productivity Impact Assessment (LAPIA) is to provide a preliminary characterization of potential changes in lake productivity as a result of the event. This report also addresses potential effects on Quesnel River.

This report provides a preliminary assessment of potential effects on the aquatic environment of the lakes and Quesnel River based on information available and understanding of the event at this time. The objective of this report was to address the potential effects on the overall aquatic health of Quesnel and Polley Lakes and Quesnel River as a result of the event. It has been structured per Department of Fisheries and Oceans (DFO) guidance on assessing fisheries productivity (Bradford et al. 2014) to facilitate the efforts of the Habitat Remediation Working Group that has been established.

Changes in productivity were assessed by comparing pre- and post-event data, where pre-event data were available, and by evaluating data in the context of the literature with consideration of site-specific conditions. Some effects are duration dependent and additional data collection is presently underway to inform the understanding of the event effects on Quesnel and Polley Lakes. A human health and ecological risk assessment (HHERA) is also planned that will more specifically address the potential effects of chemical parameters of concern in the environment.

The post-event data used in this report came from the following sources:

- The Water Quality Impact Assessment (WQIA; Golder 2015) presented water quality data collected by Mount Polley Mining Corporation (MPMC) staff and their consulting team (MPMC`s monitoring program is described in Appendix B of the WQIA) and identified key parameters that may have an effect on aquatic organisms in the receiving environment.
- The Fish and Fish Habitat Impact Assessment (FFHIA; SNC-Lavalin 2015c) identified fish species in Quesnel and Polley Lakes and Quesnel River and estimated the physical area affected by the TSF dam failure.
- The Bathymetry Analysis and Volume Balance (Tetra Tech EBA 2015a) evaluated the physical area of effect of the event in Quesnel Lake.
- The Sediment Quality Impact Characterization (Minnow 2015a) provided information regarding the potential for material introduced into Quesnel and Polley Lakes to affect fish food production.
- The Polley Lake Fish Assessment (Lirette 2015a) provided information on the condition of Rainbow Trout (*Oncorhynchus mykiss*).
- DFO provided length and weight data for fish collected from Quesnel Lake.
- The University of Northern British Columbia (UNBC) provided taxonomy and chemistry data for zooplankton collected from Quesnel Lake.

1.2 Overview of Quesnel Lake

Quesnel Lake is a large, deep fjord lake with a surface area of 266 km^2; the lake is comprised of East, West and North Arms. It is the deepest fjord-type lake in the world with a maximum depth of 511 m in the East Arm (Laval et al. 2008). The West Basin is a shallower (113 m maximum depth) portion of the West Arm separated by a 35 m deep sill near Cariboo Island. The West Basin has vertical mixing that is typical of temperate lakes, with thermal stratification for most of the year interrupted by brief turnover periods in the spring and the fall when vertical density gradients are lowest. In the deeper portions of the lake, seasonal overturn events only occur in the upper 100 to 200 m of the water column due to changes in temperature-density relationships with increased pressure at greater depths (Laval et al. 2008). The key drivers of circulation patterns in Quesnel Lake have been studied in detail (James 2004; Laval et al. 2012; Laval et al. 2008; Potts 2004) and are described in Tetra Tech EBA (2015b). Limnological data were collected between 1985 and 1988, and in 1990 by Nidle et al. (1994), providing mean values for thermocline depth (12.4 m), epilimnetic temperature (12.4°C), and euphotic zone depth (15.5 m) (Shortreed et al. 2001). Mount Polley Mine is located near the West Basin of Quesnel Lake, which received inputs from the event via water and debris flows via Hazeltine Creek.

Nidle et al. (1994) also collected water chemistry data related to lake productivity, specifically, nutrients, pH, alkalinity, and total dissolved solids (TDS). At the time of sampling, mean annual lake-wide concentrations of total phosphorus (0.0027 mg/L), nitrate (0.104 mg/L as nitrogen [N]), and total chlorophyll *a* (1.03 µg/L) were within the range for oligotrophic lakes (Shortreed et al. 2001). Annual lake-wide summaries indicated that the lake was slightly alkaline (average pH 7.2 to 7.8 relative pH units), low in TDS (59 to 66 mg/L), with low sensitivity to acid inputs (total alkalinity from 44 to 50 mg/L as calcium carbonate [$CaCO_3$]) (Nidle et al. 1994).

1.3 Overview of Polley Lake

Polley Lake is a long (6.17 km) narrow (0.65 km) lake situated adjacent to the Mount Polley Mine within a watershed area of 17.1 km^2. Minnow (2014) estimated the hydraulic residence time of the lake as approximately 16.2 years. The lake has a mean depth of 18 m and maximum depths of 35 m in the southeast basin and 33 m in the northwest basin. The main inflow to the lake is from the Frypan Lake sub-watershed situated to the north. The present configuration of Polley Lake is not its natural form; Polley Lake was dammed and its drainage modified to provide water to hydraulic mining activities that occurred in the region during the early 1900's.

Polley Lake is dimictic and mixes from the surface to the lake bottom twice each year. Thermal stratification occurs in summer with a thermocline depth between 5 and 15 m (Minnow 2014). Hypoxic conditions generally occur at depths greater than 20 m, with dissolved oxygen (DO) concentrations less than 5 mg/L. Trophic status of the lake changed from oligotrophic/mesotrophic prior to mine development to mesotrophic/eutrophic in 2012.

Minnow (2014) summarized a sub-set of water quality data collected prior to the event (2009 to 2013) at two stations (P1 and P2) and two depths (surface and bottom) in Polley Lake. Based on this summary, water in Polley Lake is characterized as clear (median turbidity of 1.1 NTU), slightly alkaline (median pH 8.9 at surface and 7.7 at bottom), moderately soft in hardness (median hardness of 104 mg/L as $CaCO_3$) based on the scale described by McNeely et al. (1979), with low sensitivity to acid inputs (median total alkalinity of 79 mg/L as $CaCO_3$) based on the scale of acid sensitivity for lakes by Saffran and Trew (1996). Median concentrations of TDS at surface and bottom ranged from 132 to 135 mg/L. Median concentrations of chloride, sulphate, nitrate, nitrite, and ammonia were less than applicable British Columbia water quality guidelines (BC WQGs; BC MoE 2015) as were median concentrations of metals[1] (Minnow 2014).

[1] The term "metal" is used in this report to encompass metals, metalloids and non-metal elements.

1.4 Overview of Quesnel River

Quesnel River is a major tributary of the Fraser River located in the Cariboo District of central British Columbia. From its outflow at Quesnel Lake it flows 100 km to the northwest, descending 2,500 m, to its confluence with the Fraser River at the City of Quesnel. The river is situated in a basin with an area of approximately 11,500 km^2 and has a mean discharge rate of 230 m^3/s (Reynoldson et al. 2010).

Limited historical water quality data for Quesnel River were obtained from a BC Ministry of Environment (BC MoE) database and are restricted to near the Town of Likely. During the sampling period (1972 to 1987) the surface water was well-oxygenated (DO from 8.5 to 13.4 mg/L), clear (turbidity ranged from 0.2 to 1.4 NTU) and characterized as soft in hardness (46 to 56 mg/L as $CaCO_3$). A pH range of 6.5 to 8.1 was identified for this river with all measurements within the BC WQG pH range. Median concentrations of chloride, ammonia, nitrate, nitrite, and sulphate were less than their corresponding BC WQGs. Metals data were limited for Quesnel River; however, data for aluminum, chromium, copper, iron, lead, manganese, and zinc indicated that concentrations for these metals were less than BC WQGs.

2.0 CONCEPTUAL LAKE ECOLOGICAL MODEL

The interaction between biotic and abiotic factors in a lake is complex and in many cases it is unknown how a disruption will ultimately affect the overall productivity of a lake and its fisheries. In its most simple form, productivity begins with phytoplankton in open-water and attached algae (peri- and epiphyton) in near-shore, shallower areas harnessing energy from the sun (Figure 2). These primary producers may then be consumed by invertebrates or by fish directly and then carnivorous fish eat the invertebrates and grazing fish. Productivity may change when one or more of these linkages are affected.

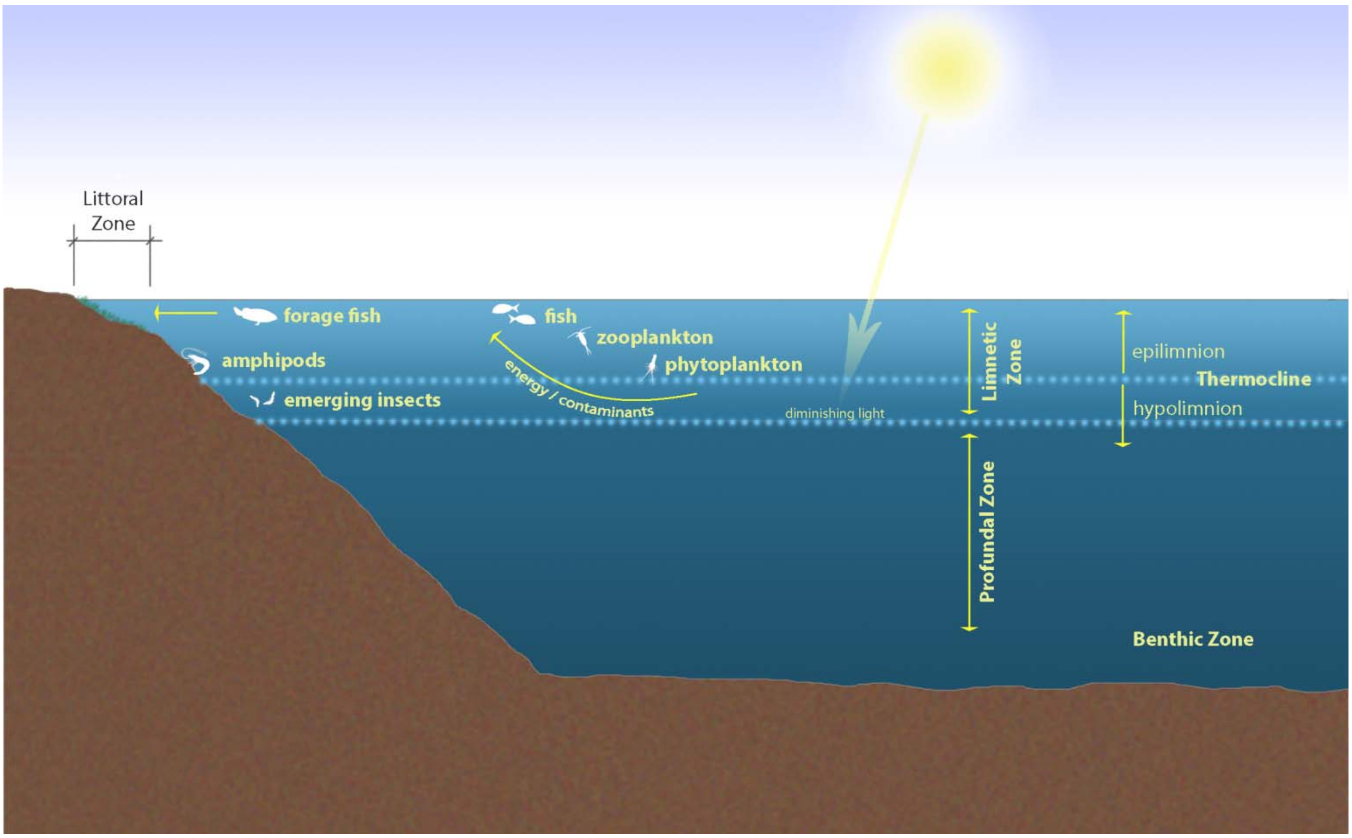

Figure 2: Generalized Conceptual Ecological Model for a Lake

Figure 2 contains several terms that are used throughout this report:

- **Benthic** – associated with the lake bottom.
- **Emerging insects** – insects that have a water-based larval stage and a flying adult stage.
- **Epilimnion** – the water column above the thermocline.
- **Hypolimnion** – the water column below the thermocline.
- **Limnetic zone** – the portion of the water column through which light penetrates.

- **Littoral zone** – the area of the lakeshore where aquatic plants grow. In Quesnel Lake, this area is 4 to 6 m deep.
- **Phytoplankton** – free-floating plants/algae and photosynthetic bacteria.
- **Profundal zone** – the portion of the water column that light does not reach and as a result does not support plant growth.
- **Thermocline** – a sharp density gradient in the water column that limits mixing of the water column which is caused by differences in temperature between the upper and lower water column. In the summer, the surface of the water column is warmer and the water at depth is cooler.
- **Zooplankton** – free-floating invertebrates.

2.1 Quesnel Lake

To facilitate the assessment of potential effects on the productivity of Quesnel Lake, a conceptual ecological model was developed for fish-habitat-food assemblages. Table 1 summarizes relevant life history and feeding habits of the 20 fish species identified in the FFHIA (SNC-Lavalin 2015c). These habitat and food requirements were grouped, resulting in three general assemblages applicable to a summer condition when the lake was stratified. This time period represents when the event occurred. When the lake is not stratified, fish usage of different parts of the lake may change. For example, Lake Trout (*Salvelinus namaycush*) are temperature sensitive and may stay below the thermocline during the summer whereas after the thermocline barrier has degraded and the lake has mixed, the fish will occupy the entire limnetic zone (McPhail 2007). Their food preference also changes from plankton during the summer to fish when the lake is not stratified.

Table 1: Summary of life history characteristics considered in conceptual ecological model

Species	Life Stage	Habitat	Food Habits	Notes
Anadromous Salmon				
Sockeye (*Oncorhynchus nerka*)	Juvenile	Littoral/pelagic	Chironomids, crustacean zooplankton initially, then crustacean zooplankton	First 5 weeks after hatching, juveniles occupy the littoral zone and after 5 weeks move off-shore and undertake diel (daily) vertical migration to 60 to 80 m during day and as shallow as 5 m at night. Some evidence that they orient to thermocline depth at night in Quesnel Lake.
	Adult	Open-water	NA	Migrate through lake to natal streams in August and September; no significant lake usage except lake spawners (lake spawning has not been observed in the West Arm of Quesnel Lake).
Coho (*O. kisutch*)	Juvenile/Adult	Open-water	Incidental	Migrate through lake to/from natal streams.
Chinook (*O. tshawytscha*)	Juvenile/Adult	Open-water	Incidental	Migrate through lake to/from natal streams.
Other Salmonids				
Kokanee (*O. nerka*, freshwater variant)	Juvenile	Littoral/open-water	Chironomids, crustacean zooplankton	YOY may forage in the littoral zone or move offshore. Juveniles undergo the same diel vertical migration as adults.
	Adult	Open-water	Crustacean zooplankton	Diel vertical migration during summer; feeding near surface at dawn and dusk, residing below the thermocline during the day and at night.
Rainbow Trout (*O. mykiss*)	Juvenile	Littoral	Benthic prey (amphipods, aquatic insects such as chironomids), plankton (crustacean zooplankton)	Inshore during winter and spring, occupying areas with cover except at night when they move over sand and gravel to feed. May move offshore in spring and summer.
	Adult	Open-water	Emerging insects, zooplankton; larger adults also eat other fish (e.g. Sockeye, Kokanee).	Diel vertical migration; more active at dawn and dusk. Spring spawning migration and summer feeding migration to Horsefly and Mitchell Rivers.

Species	Life Stage	Habitat	Food Habits	Notes
Lake Trout (*Salvelinus namaycush*)	Juvenile	Open-water	YOY – plankton; Juvenile – benthic prey	Tend to occupy deeper water than adults.
	Adult	Open-water	Fish, except in summer when they may eat plankton	During summer tend to be below the thermocline.
Bull Trout (*S. confluentus*)	Juvenile	Open-water	Aquatic insects	Rear in streams for first years; when they enter lakes they initially occupy deeper water than adults.
	Adult	Littoral (fall and spring); Open-water (summer)	Fish	Can feed under low-light conditions; shore-ward migration at night.
Lake Whitefish (*Coregonus clupeaformis*)	Juvenile	Littoral	Crustacean zooplankton	Move to deeper waters in summer and continue to descend in winter.
	Adult	Open-water	Benthic prey (chironomids, amphipods, gastropods, small fish)	Below thermocline during summer.
Mountain Whitefish (*Prosopium williamsoni*)	Juvenile	Littoral	Plankton	Remain inshore in <2 m water depth through spring and summer
	Adult	Littoral (spring/fall); Open-water (summer/winter)	Plankton, surface insects	Generally in upper 20 m of water column and found in low numbers in the limnetic zone.
Pygmy Whitefish (*P. coulterii*)	Adult	Off-shore	Benthic prey	Usually in 20 to 40 m of water; shore-ward migration at night.
Benthic Fish				
Burbot (*Lota lota*)	Juvenile	Littoral	Benthic prey – amphipods	Larvae initially limnetic, in spring become benthic. Associated with gravel, cobble and rubble substrate.
	Adult	Littoral (fall and winter); Off-shore (summer)	Fish (suckers, minnows, sculpin, trout)	Associated with gravel, cobble and rubble substrate. In summer, found offshore near the hypolimnion where they seek dark areas; vertical migration in summer; feed at night. In winter, move to shallower littoral areas. Spawn in winter.

Species	Life Stage	Habitat	Food Habits	Notes
Largescale Sucker (*Catostomus macrocheilus*)	-	Littoral/off-shore	Adults – benthic prey; Juveniles - plankton	Found above and below thermocline; horizontal migration (onshore at dawn and offshore at night).
Longnose Sucker (*C. catostomus*)	-	Littoral/off-shore	Benthic prey – chironomids	Adults forage inshore at night and remain below thermocline during the day.
Slimy Sculpin (*Cottus cogantus*)	-	Littoral/near-shore	Benthic prey – chironomids, amphipods, salmon eggs	May occur in deeper (4 to 10 m) water during summer. Feed at night. Tolerant of turbidity.
Forage Fish				
Northern Pikeminnow (*Ptychocheilus oregonensis*)	-	Littoral	Juveniles – crustacean zooplankton, chironomids; Adults – fish	Feed dusk to dawn, oriented to lake bed.
Peamouth Chub (*Mylocheilus caurinus*)	-	Littoral/near-shore	Plankton, benthic prey, aquatic insects	Adults forage in both the littoral and limnetic zone. School in shallow, vegetated areas oriented to lake bed.
Lake Chub (*Cousesius plumbeus*)	-	Littoral/near-shore	Benthic prey	Usually found at 0.5 to 10 m depth on bottom. May move to deeper water during the day in summer.
Leopard Dace (*Rhynichthys falcatus*)	-	Littoral	Periphyton, some aquatic insects.	Inhabit rocky, low gradient beaches with aquatic vegetation offshore.
Longnose Dace (*R. cataractae*)	-	Littoral/near-shore	Benthic prey	Horizontal migration between on-shore during day and off-shore at night; feed at night, oriented to lake bed.
Redside Shiner (*Richardsonius baleatus*)	-	Littoral/off-shore	Crustacean zooplankton, aquatic insects, eggs and fry of other fish	Usually found at <4 m depth in littoral zone during the day; horizontal migration offshore at night.

Notes:
Sources: Levy et al. (1991); McPhail (2007); Morton and Williams (1990); Parkinson et al. (1989); Roberge et al. (2001); Scott and Crossman (1973); Sebastian et al. (2003)
"<" - less than; m – metre; YOY – young of year

The significance of the three fish assemblages is how potential stressors related to the event may affect productivity as discussed in the framework presented in Section 3.0. The three fish/habitat assemblages identified were as follows:

Littoral Zone and Benthic Habitats

Fish associated with the littoral zone and benthic habitats (Figure 3) are oriented to the near-shore environment and feed largely on benthic prey (e.g., amphipods, larvae and pupae of aquatic insects such as chironomids, which are also known as midges), periphyton, or in some cases plankton (crustacean zooplankton) in the water column (McPhail 2007; Scott and Crossman 1973). Fish in this group include juvenile stages of salmon (*Oncorhynchus* spp.) and Burbot (*Lota lota*), Lake Whitefish (*Coregonus clupeaformis*) which preferentially inhabit the lake below the thermocline in the summer and are benthivores (i.e., their food comes from benthic substrates), and forage fish such as sucker, sculpin, chub, shiner and Northern Pikeminnow (*Ptychocheilus oregonensis*). The forage fish have a range of feeding habits and may consume primarily benthic invertebrates or periphyton, or in the case of Northern Pikeminnow, eat other fish (i.e., they are piscivorous). Other fish considered in this assemblage are adult Burbot, which are also piscivorous, and make vertical migrations in the summer to feed on trout, minnow, sucker and sculpin.

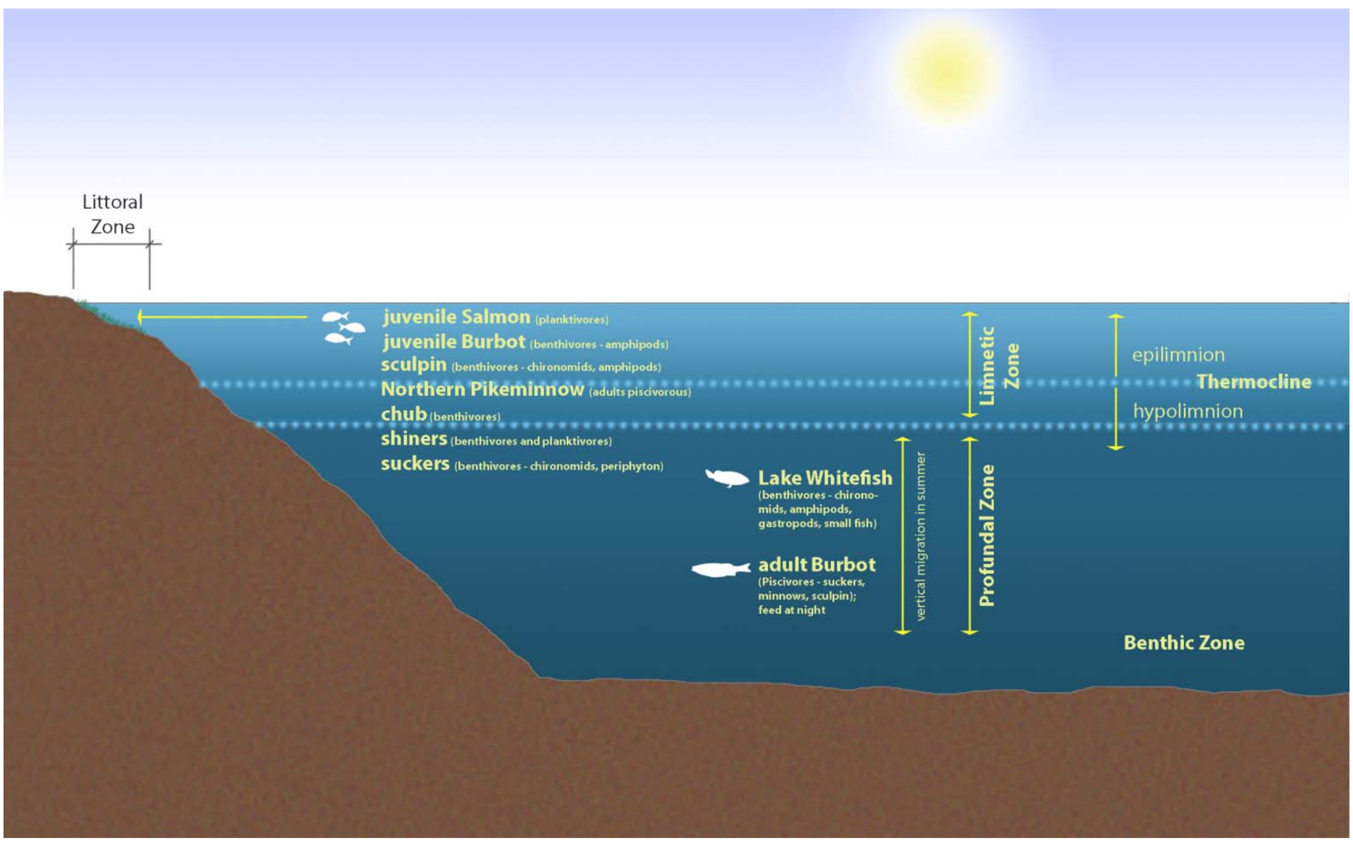

Figure 3: Conceptual Ecological Model for Littoral Zone and Benthic Habitats

Open-water Habitat and Fish that Feed on Emerging Insects

Fish associated with open-water habitat and feed on emerging insects (e.g., chironomids; Figure 4) include Mountain Whitefish (*Prosopium williamsoni*), which typically inhabit the upper 20 m of the water column, and smaller Rainbow Trout (*Oncorhynchus mykiss*), which undertake a diel (i.e., daily) vertical migration (McPhail 2007; Scott and Crossman 1973). Larger adult Rainbow Trout in Quesnel Lake may consume juvenile Sockeye Salmon (*Oncorhynchus nerka*) and Kokanee (*O. nerka*; freshwater variant; Parkinson et al. 1989).

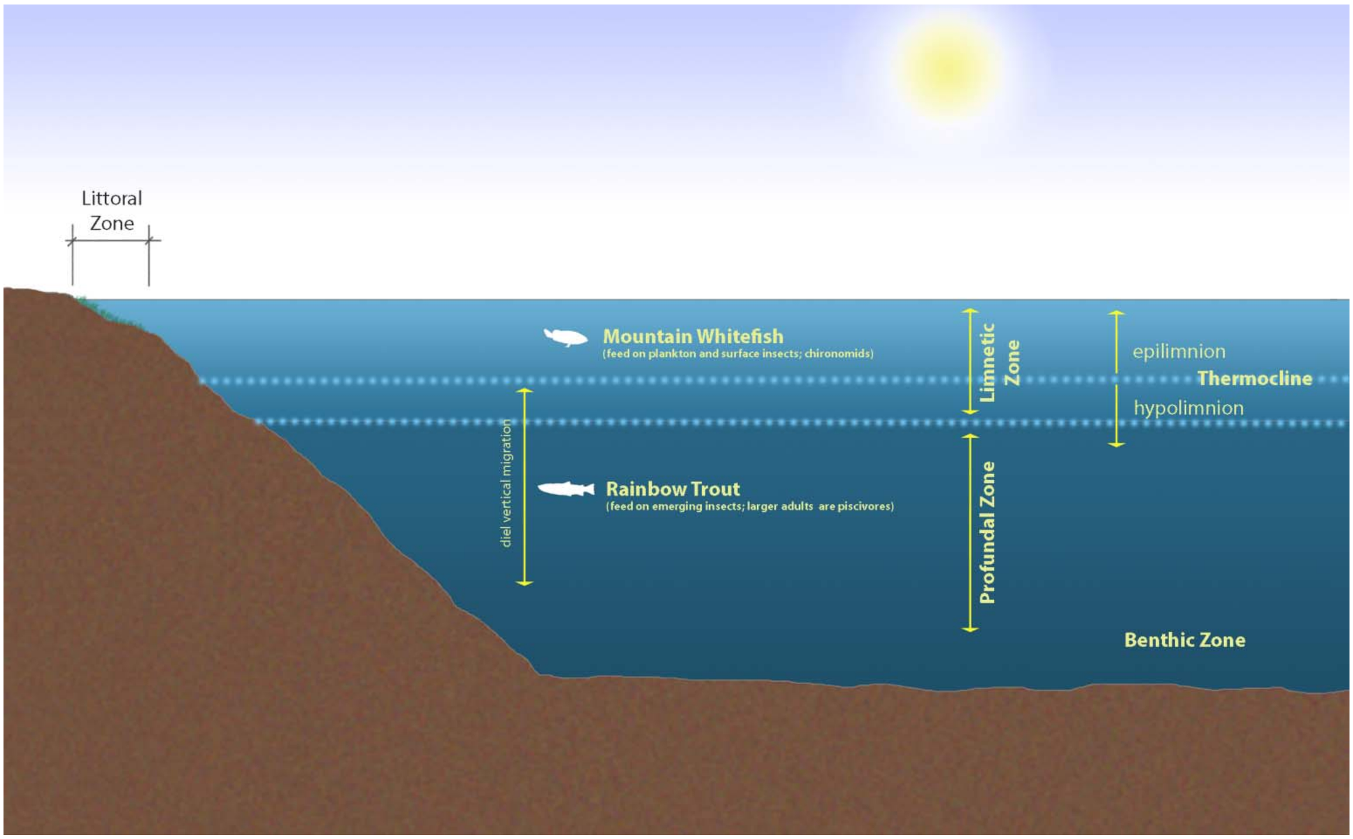

Figure 4: Conceptual Ecological Model for Open-water Habitat and Fish that Feed on Emerging Insects

Open-water Habitat and Fish that Feed on Crustacean Zooplankton

The assemblage of fish associated with open-water habitat and which feed on crustacean zooplankton (Figure 5) consists of juvenile Sockeye Salmon which undertake a diel vertical migration, orienting to the lower boundary of the thermocline at night (Levy et al. 1991) and descending to 60 to 80 m depth at night (McPhail 2007; Morton and Williams 1990; Scott and Crossman 1973). Kokanee also undertake a vertical migration, generally feeding near surface at dawn and dusk, and staying below the thermocline during the day and at night. During the summer, this assemblage may also include Lake Trout.

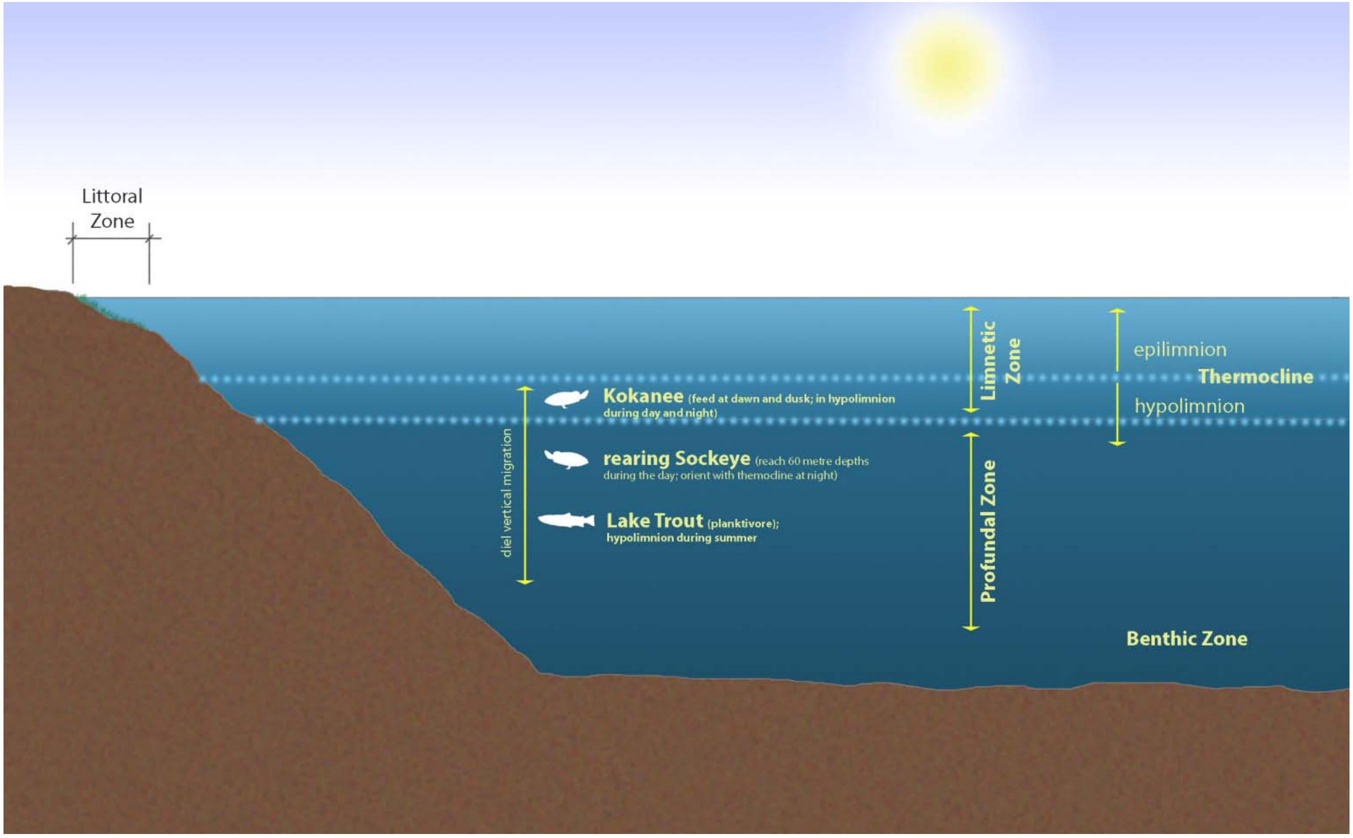

Figure 5: Conceptual Ecological Model for Open-water Habitat and Fish that Feed on Crustacean Zooplankton

2.2 Polley Lake

The conceptual ecological model for Polley Lake is a simplified version of that of Quesnel Lake. Rainbow Trout was the only CRA fish species identified by SNC-Lavalin (2015c). Other fish in the lake include Longnose Sucker and Redside Shiner. The conceptual model for open-water habitat and fish that feed on emerging insects described in Section 2.1 is applicable to Rainbow Trout.

3.0 FRAMEWORK FOR ASSESSING PRODUCTIVITY

DFO has developed a framework for assessing the potential for impacts to productivity from activities or undertakings (Bradford et al. 2014; Tupper de Kerckhove 2015). The framework starts with a generic fish life cycle and Components of Productivity (Figure 6), with the understanding that different habitats may be important for the different life stages of a fish and that different Pathways of Effect may have more or less influence on changes in those habitats. More specific life-cycle information for Quesnel and Polley Lake fish is provided in Section 2.0 (Table 1).

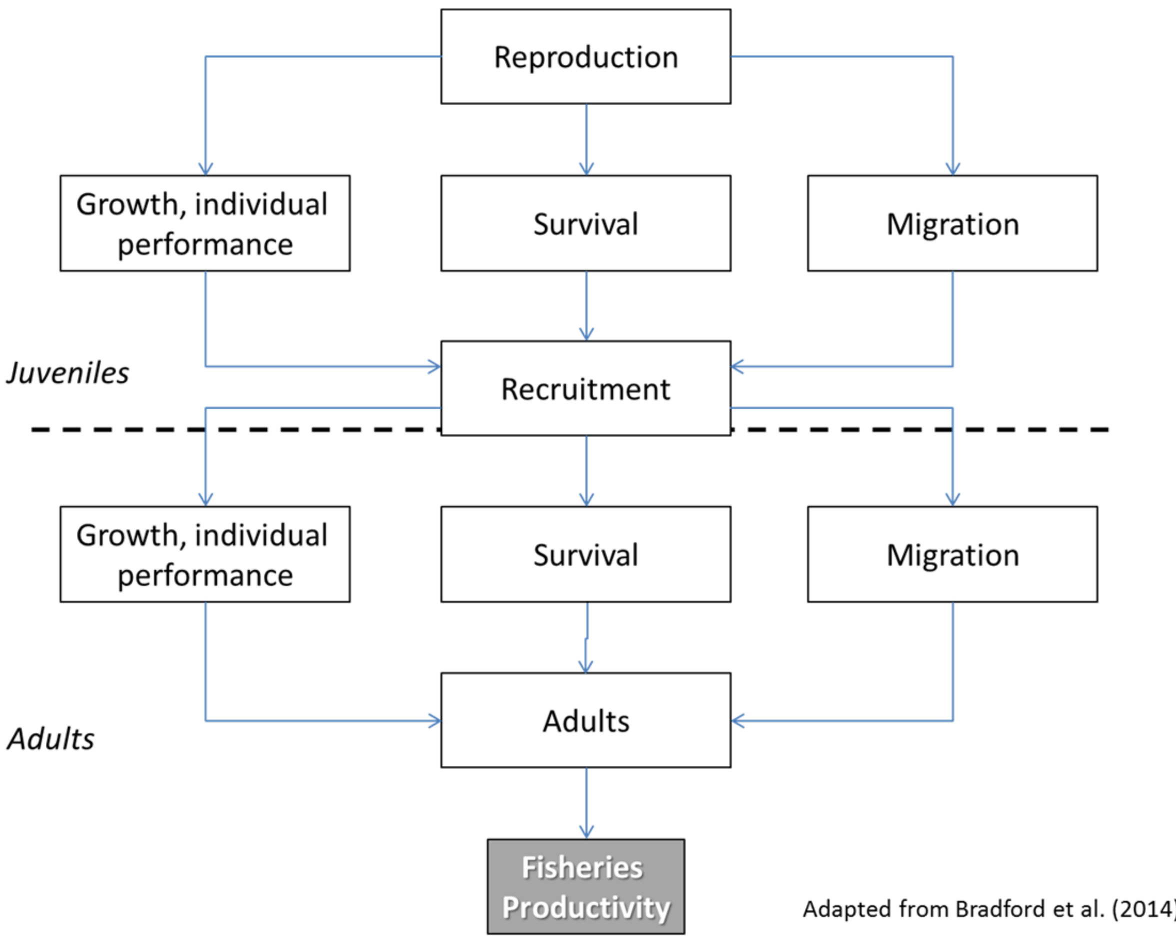

Figure 6: Generalized Fish Model with Major Components of Productivity

In the productivity framework, a **Pathway of Effects** is a specific activity or change in conditions that may affect Components of Productivity. For example, for the TSF dam failure, a Pathway of Effect was the introduction of debris from Hazeltine Creek onto the lakebed and into the water column of Quesnel Lake. A **Component of Productivity** is an aspect of fish productivity such as growth, survival, individual performance, or reproduction that may be altered by a change in conditions and a **Sub-component of Productivity** contributes to a

Component of Productivity. For example, sub-components of growth include food availability (quality and quantity) and feeding/foraging efficiency. **Indicators** are measures for predicting a change in a Component of Productivity. These may be qualitative or descriptive where there is a lack of data, or may be quantitative when sufficient information and understanding exist to accurately estimate change. Finally, **Measurements** are specific endpoints that can be used to describe changes in a given component or sub-component of productivity, for example the length and weight of a fish, or zooplankton abundance.

Table 2 summarizes the framework for assessing effects to fisheries productivity in Quesnel Lake and Table 3 summarizes the framework for Polley Lake, including the components and sub-components of productivity, the mechanisms of effect, the type of indicator that will be used (i.e., qualitative or quantitative), and information available to measure the effect. Table 2 is used in Section 4.0 to summarize the assessment for each of the three fish assemblages identified in the conceptual ecological model for Quesnel Lake (Section 2.1). Table 3 is used in Section 5.0 to summarize the assessment for each of the fish assemblage identified in the conceptual ecological model for Polley Lake (Section 2.2).

At this time, the indicators used in this preliminary assessment are qualitative and inferences are made based on the available data. No predictions or modelling of changes in overall fish populations are included in this report.

Table 2: Framework for Assessing Impact to Fisheries Productivity in Quesnel Lake

Component of Productivity	Sub-component	Mechanism	Indicator		Information Available / Measurement
			Qualitative	Quantitative	
Survival	Density independent mortality	Direct mortality	Yes	No	■ Literature information regarding potential direction of change. ■ No data on numbers of fish present or area of habitat occupied at the time of the event. ■ No data on potential mortality.
		Exceedance of environmental tolerances	Yes	No	■ Water toxicity test data. ■ Literature information regarding potential direction of change. ■ No data on numbers of fish present or area of habitat occupied at the time of the event.
	Habitat quality or quantity	Habitat supply limitation	Yes	No	■ Area of littoral and benthic habitat affected.
Growth	Fish Growth	-	Yes	No	■ Water toxicity test data. ■ Length and weight data for Sockeye Salmon juveniles; comparison between reference and exposed stations and historical data.
	Food supply	Quantity	Yes	No	■ Water column measurements: ▪ Nutrient concentrations. ▪ Chlorophyll *a* measurements. ▪ Water toxicity test data. ■ Sediment/benthic habitat measurements: ▪ Sediment toxicity test data. ▪ *In situ* benthic invertebrate community data. ■ Zooplankton community abundance and composition. ■ Comparison between reference and exposed stations. ■ Comparison with historical data where available.

Component of Productivity	Sub-component	Mechanism	Indicator		Information Available / Measurement
			Qualitative	Quantitative	
Growth cont.	Food supply cont.	Quality	Yes	No	■ Zooplankton tissue chemistry; comparison between reference and exposed stations. ■ No information on benthic invertebrate tissue chemistry.
	Efficiency	Foraging	Yes	No	■ Literature information regarding potential direction of change in feeding based on turbidity measurements. ■ Length and weight data for Sockeye Salmon juveniles; comparison between reference and exposed stations and historical data.
		Bioenergetics	Yes	No	■ Literature information regarding potential direction of change in feeding based on turbidity measurements. ■ Length and weight data for Sockeye Salmon juveniles; comparison between reference and exposed stations and historical data.
	Stress	Suboptimal environmental conditions	Yes	No	■ Water toxicity test data. ■ Literature information regarding direction of change based on turbidity measurements.
	Olfactory effects	Suboptimal environmental conditions	Yes	No	■ Literature information regarding direction of changed based on copper concentrations. ■ Data on adult Sockeye Salmon returns.
	Disease	Infection	Yes	No	■ Literature information regarding potential direction of change. ■ No data on potential infection.
Migration	-	Disruption of normal behaviour	NA	NA	■ Event did not block migratory routes through Quesnel Lake.

Component of Productivity	Sub-component	Mechanism	Indicator		Information Available / Measurement
			Qualitative	Quantitative	
Reproduction	Adult maturation	Suboptimal environmental conditions	Yes	No	■ Literature information regarding potential direction of change.
	Density-independent reproductive success	Spawning habitat quality	Yes	No	■ Water toxicity test data ■ Condition of spawning habitat following the event.
	Density-dependent reproductive success	Spawning habitat quantity	Yes	No	■ Area of spawning habitat altered.

An additional factor that is important to the assessment of effects on fisheries productivity is the timing of the event and associated changes to water quality and habitat relative to the general cycle in rate of productivity. For example, Figure 7 illustrates a conceptual model of productivity in an unaffected generic lake environment which is directly related to the Component of Productivity growth. In the spring, the biomass of phytoplankton increases rapidly as light intensity increases and in response zooplankton biomass will increase after a lag period (Wetzel 2001). This is then followed by increasing biomass in fish such as Sockeye Salmon that consume those zooplankton. The event occurred during the late summer and a substantial degree of plankton and fish biomass may already have been accumulated. Thus, the potential for effects to productivity of fish would be relative to the incremental change that would have occurred after the event. Similarly, during lake turnover and the increase in turbidity observed through the water column of Quesnel Lake (Golder 2015), productivity would naturally be declining and the effect would again be incremental.

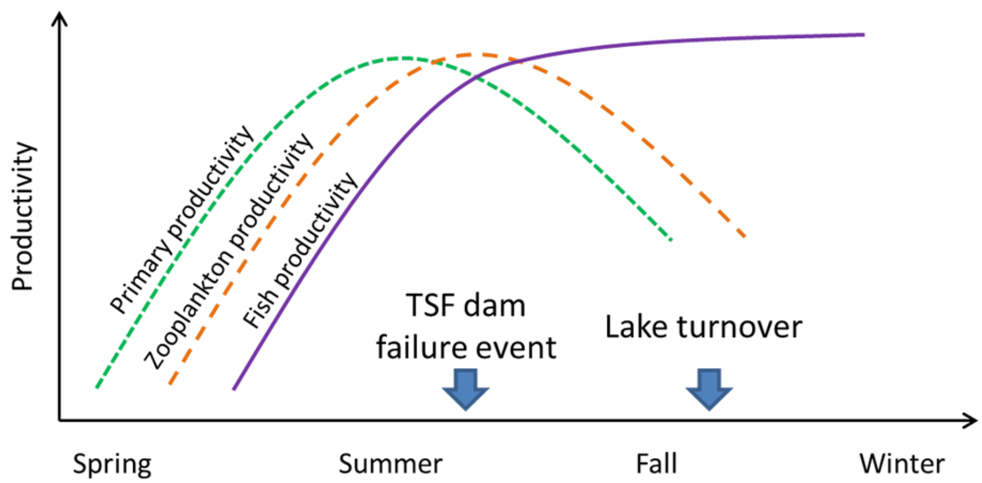

Figure 7: Conceptual Lake Productivity Model Under Natural Conditions (Not Actual Data from Quesnel Lake)

4.0 QUESNEL LAKE IMPACT ASSESSMENT

This section addresses the Components of Productivity summarized in Table 2 for Quesnel Lake.

4.1 Survival

4.1.1 Direct Mortality of Fish

It is possible that fish occupying the littoral zone at the mouth of Hazeltine Creek were entrained in the debris or they may have been displaced in advance of the debris reaching the lake. However, dead fish were not observed and this potential effect on productivity cannot be quantified.

4.1.2 Exceedance of Environmental Tolerances

Servizi and Gordon (1990) and Servizi and Martens (1987) undertook studies on the acute lethality of suspended Fraser River sediments on juvenile Chinook (*Oncorhynchus tshawytscha*) and Sockeye Salmon, respectively. Juvenile Chinook Salmon were almost twice as tolerant as juvenile Sockeye with 96-h LC_{50} values of 31,000 mg/L and 17,600 mg/L, respectively. Servizi and Martens (1991) found that smaller fish were more susceptible to suspended solids-induced mortality than larger fish. Data were not available in the period immediately (e.g., hours to days) after the event. However, the on-going monitoring program reported TSS levels less than 50 mg/L (Figure 8). No dead fish were observed and this potential effect on productivity cannot be quantified with available data.

Minnow (2015b) reported on a total of 53 toxicity tests (acute and chronic) using six different species that were carried out on water samples collected between August and September 2014 from Polley Lake, the discharge from Polley Lake into Hazeltine Creek, Quesnel Lake, and the Quesnel River. Quesnel Lake water samples were taken from the monitoring station closest to the source of event-related inputs at the mouth of Hazeltine Creek. Additional water samples were collected from November 2014 to February 2015 with a focus on sublethal toxicity testing. The fish tests included the following:

- 96-h acute lethality to Rainbow Trout (first sampling event); and
- 7-d survival and growth of Fathead Minnow (*Pimephales promelas*; representative of forage fish that may occupy the littoral zone) (first and second sampling events).

The water collected from Quesnel Lake was not acutely toxic to Rainbow Trout, and survival of Fathead Minnow in the 7-day test was not affected.

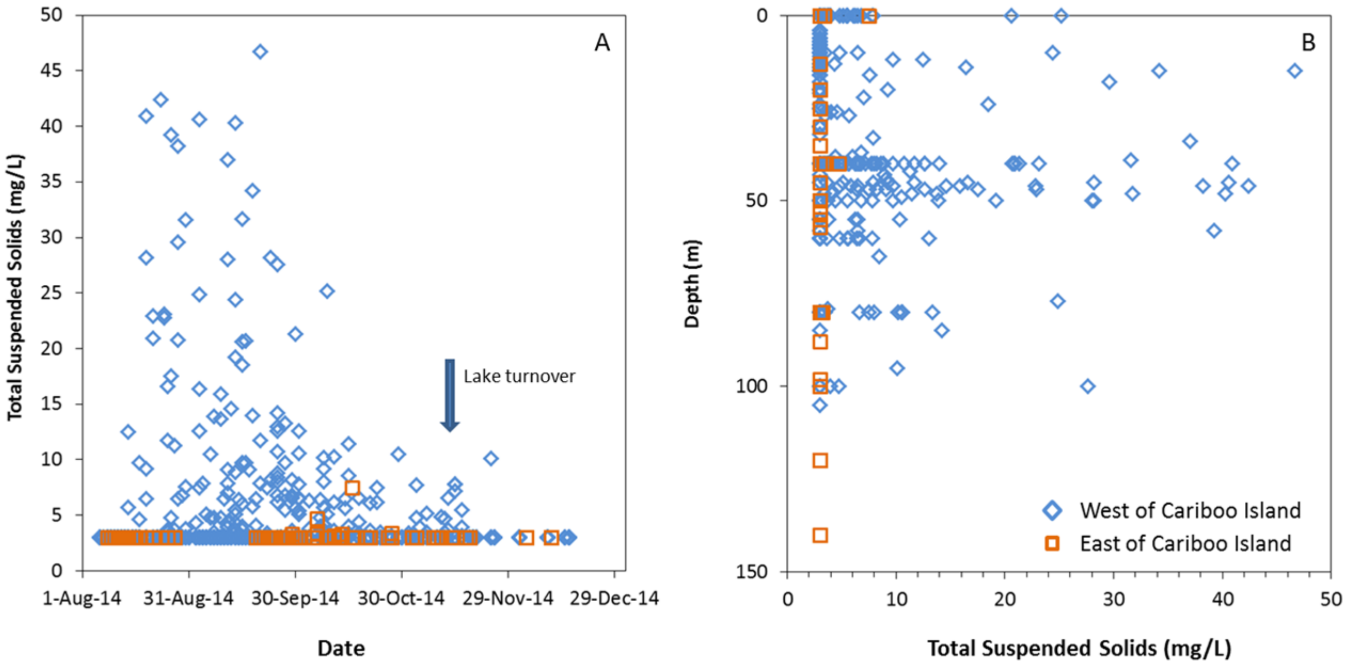

Figure 8: Spatial and Temporal Variability in Total Suspended Solids Concentration in the West Arm of the West Basin (West of Cariboo Island; 23 stations) Compared to the Middle Arm (East of Cariboo Island; 10 stations) of Quesnel Lake by Sampling Date (A) and Depth (B)

4.1.3 Habitat Quantity or Quality

The littoral zone at the mouth of Hazeltine Creek was altered as a result of the event, estimated to be 0.094 km^2 in area (SNC-Lavalin 2015c). This is approximately 6.5% of the West Basin littoral zone. Approximately 1.81 km^2 of the lake bed below the 100 m contour was covered by debris from Hazeltine Creek (Tetra Tech EBA 2015a).

The physico-chemical quality and toxicity of lake sediments were addressed by Minnow (2015a). The particle-size distribution of sediment immediately to the east of Hazeltine Creek consisted of a higher proportion of silt (mean of 85%) than other littoral sampling locations (mean of 30 to 54%) whereas on the lakebed (i.e., in the profundal zone) immediately off-shore from Hazeltine Creek had a similar grainsize distribution as several reference areas. Total organic carbon content was lower in the immediately affected area when compared to the reference areas.

Standard toxicity test organisms were evaluated under laboratory conditions using established protocols to determine if benthic-dwelling organisms could survive and grow normally (Minnow 2015a). In several samples, these organisms did not survive or grow as successfully as those exposed to reference sediment. The specific cause of toxicity was difficult to determine because the composition of newly deposited tailings-influenced sediments differs from natural sediment. For example, the organic carbon in the sediment, which is a food source to the test organisms, was low in many samples. When poor performance was observed in growth or survival, samples also contained much less organic carbon than recommended in test protocols for normal performance of the tests. It is therefore possible that apparent effects in some samples was due to food limitations, chemical influence, or both factors acting together. However, the study also provided indications of normal growth and survival in sediments that were collected distant from the areas of greatest tailings influence (i.e., Quesnel Lake locations distant from Hazeltine Creek).

4.2 Growth

4.2.1 Fish Growth

The growth of fish themselves is a time-integrated measure of the cumulative influence of the number of factors that contribute to their wellness or productivity, such as food supply and exposure to contaminants and other potential stressors like turbidity (Rand and Petrocelli 1985). Organism growth and development also requires the simultaneous function of numerous cellular and sub-cellular processes, each of which could be potential targets for toxicants. Successful growth is therefore an indication that such toxic effects are not occurring. As it relates to the post-event impacts, information regarding growth is available from test organisms used in laboratory-based water toxicity tests and from fish collected from the receiving environment.

Growth of Fathead Minnow was not affected in the 7-day survival and growth tests conducted in water from Quesnel Lake between August and September 2014 and November 2014 and February 2015 (Minnow 2015b).

DFO collected Sockeye Salmon juveniles from mid-net depths of approximately 20 m from four locations in Quesnel Lake between September 23 and 27, 2014, and measured length and weight (D. Selbie, DFO, pers. comm.). The fish collected from the West Arm west of Cariboo Island were larger than the fish collected from east of Cariboo Island (Figure 9). Fish collected from the West Arm in 2014 were also notably larger than fish collected from the same location in 2013 (Figure 10). These data suggest that a change in foraging efficiency by juvenile Sockeye Salmon may not have occurred, perhaps because *Daphnia* have been found to occupy the upper 10 m of the water column during the summer (Levy 1990; Morton and Williams 1990) where turbidity was relatively low. Another possible explanation is that a change in foraging efficiency did occur but was offset by a larger food supply that may have resulted from the influx of phosphorus into the lake (Section 4.2.2.1). Data regarding the growth of other fish species was not available.

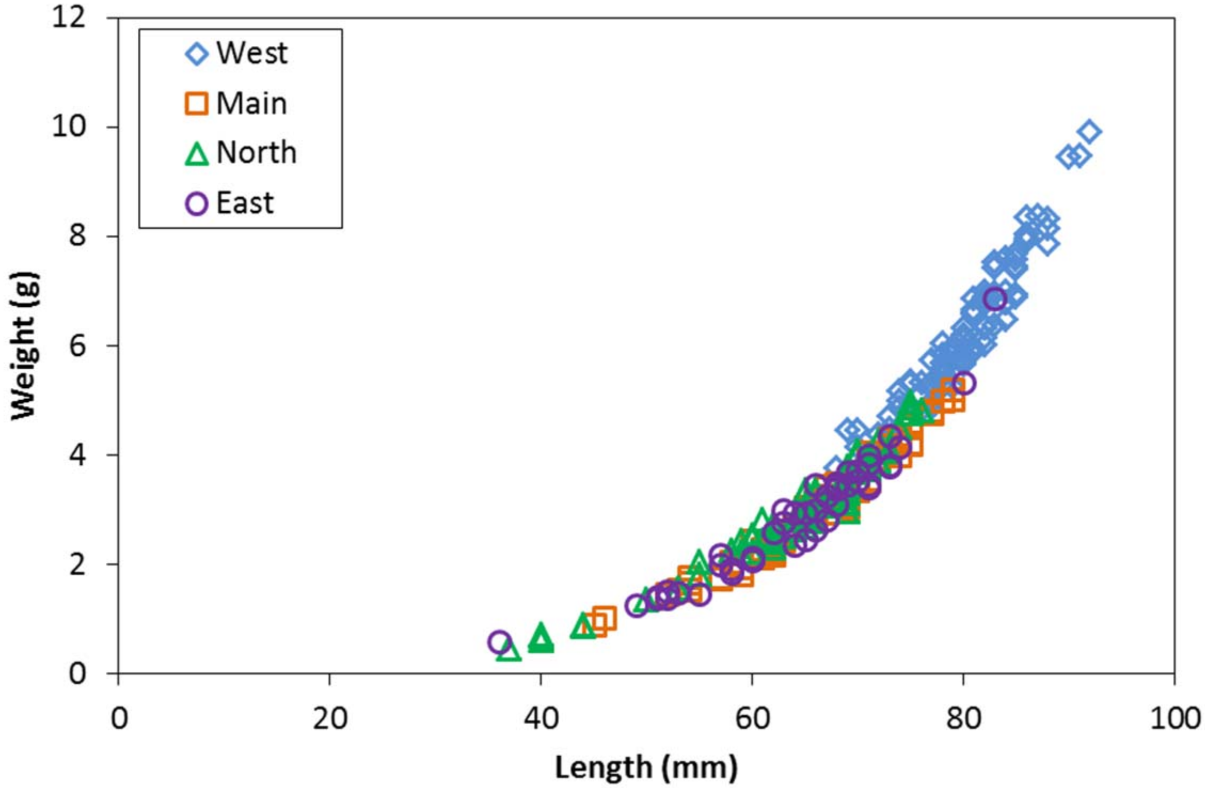

Figure 9: Length and Weight of Age 0+ Sockeye Salmon Collected from Exposed (West) and Reference (Main, North, East) Areas of Quesnel Lake Between September 23 and 27, 2014 (Data Courtesy of DFO)

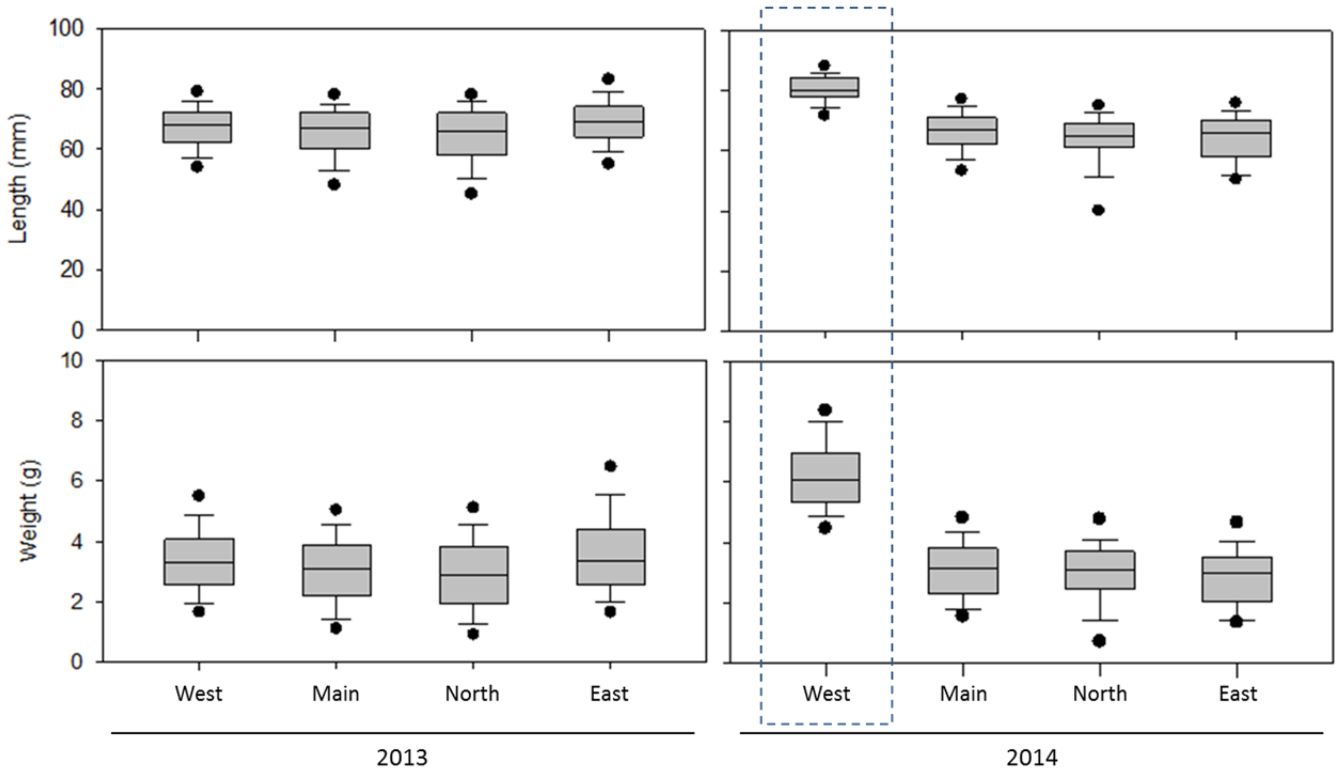

Figure 10: Comparison of Age 0+ Sockeye Salmon Length and Weight Between Exposed (West) and Reference (Main, North, East) Areas of Quesnel Lake and Pre- (2013) and Post-event (2014) (Box-plots Courtesy of D. Selbie, DFO)

4.2.2 Food Supply - Quantity

4.2.2.1 Nutrient Inputs

Introduction of suspended sediments can release nutrients and result in increased productivity (Schallenberg and Burns 1998) and mean total phosphorus concentrations have been correlated with fish production (Downing et al. 1990). As illustrated in Figure 11, there was an initial influx of phosphorus and possibly dissolved organic carbon in August. Total phosphorus concentrations were higher than pre-event conditions as well as those measured outside the West Basin, at depth (>20 m) in particular, but also in shallower water (<20 m). The dissolved phosphorus fraction was relatively lower and thus it was inferred that the phosphorus was associated with suspended particles deeper in the water column. There is some uncertainty about the type of phosphorus that may have been introduced to Quesnel Lake by the event. The phosphorus associated with the TSF is presumed to be in the mineral apatite form, which is not readily soluble. However, there is some evidence of partial dissolution of apatite to biologically-available orthophosphate at pH levels similar to those observed in Quesnel Lake (Smith et al. 1997). There appeared to be an increase in dissolved organic carbon in the top 20 m of the water column and thus it is also possible that the natural sediment and debris scoured from Hazeltine Creek contained biologically available phosphorus. Regardless of the source, given that Quesnel Lake is oligotrophic, even a relatively small increase in phosphorus could result in a rapid increase in primary productivity followed by an increase in productivity at higher trophic levels. This process is relatively efficient (i.e., utilization of phosphorus may be rapid) in oligotrophic lakes (Downing et al. 1990).

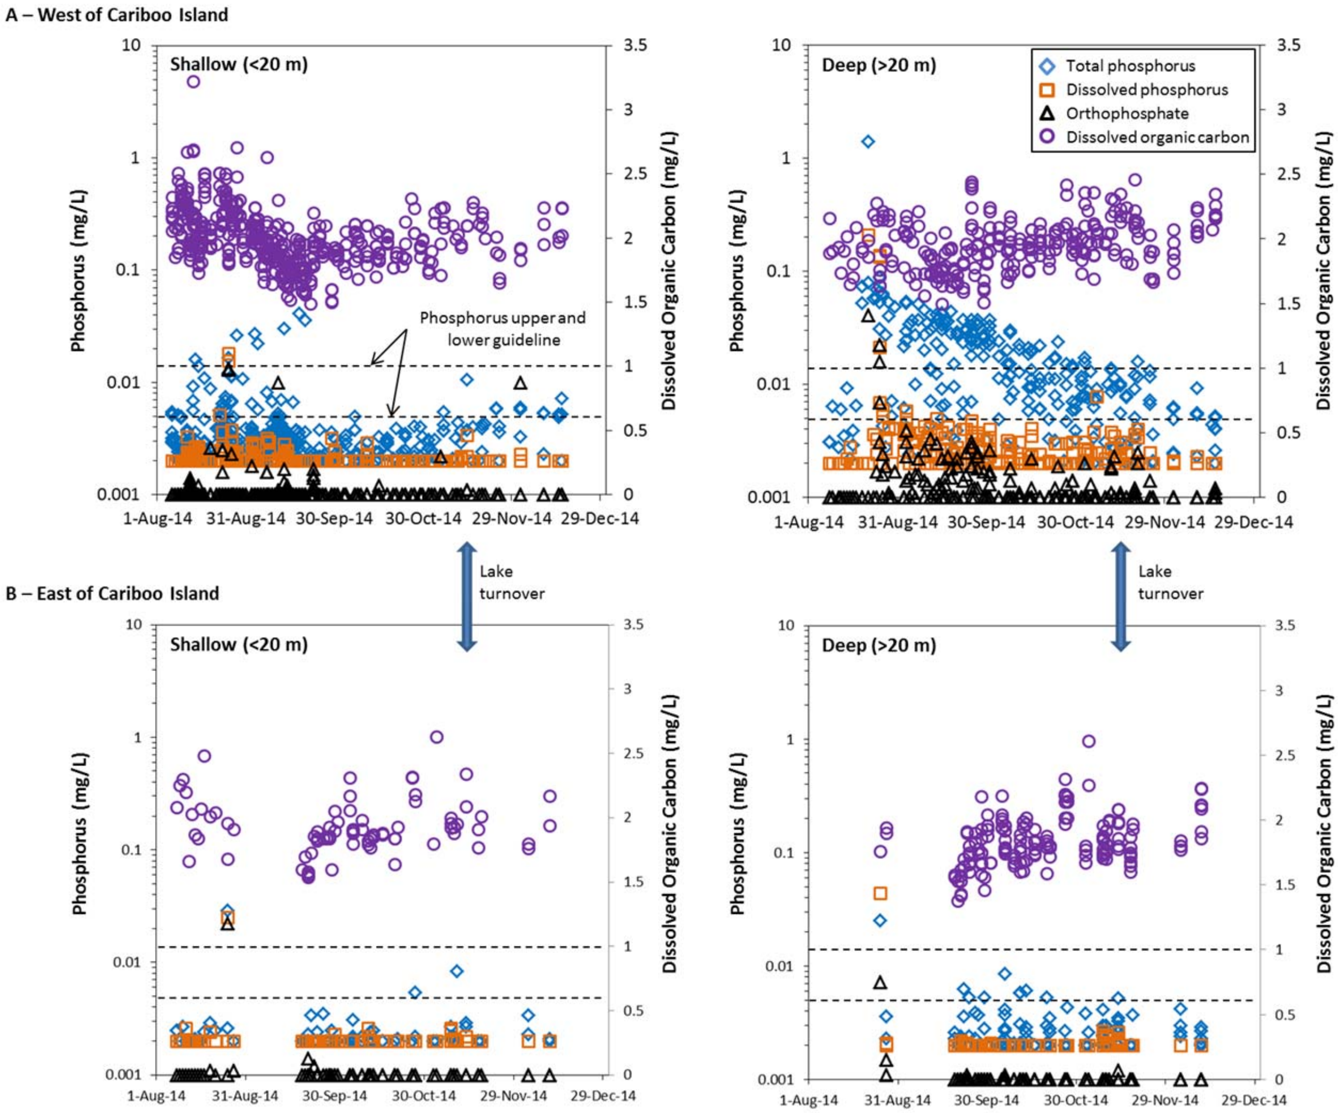

Figure 11: Temporal and Spatial Variability in Phosphorus and Dissolved Organic Carbon in Shallow (<20 m) and Deep (>20 m) Waters in (A) the West Arm of the West Basin (West of Cariboo Island; 23 stations) Compared to (B) the Middle Arm (East of Cariboo Island; 10 stations) of Quesnel Lake

4.2.2.2 Primary Productivity

Minnow (2015b) reported the findings of two plant tests conducted on water from Quesnel Lake:

- 7-d growth inhibition in the vascular aquatic plant *Lemna minor;* and
- 72-h growth inhibition in the alga *Pseudokirchneriella subcapitata* (formerly named *Selenastrum capricornutum*).

There was no impairment of growth of either test species, including in turbid water from a deeper sampling location in Quesnel Lake.

The direction of change in primary productivity as a result of introduction of suspended sediments to a lake depends on whether the phytoplankton are light limited or nutrient limited (Northcote et al. 2005; Schallenberg and Burns 2004; Schallenberg et al. 2001). Suspended sediment can inhibit photosynthesis by changing the depth to which light penetrates or can contribute nutrients that may be used by phytoplankton in an oligotrophic system as discussed in Section 4.2.2.1.

Data that provide an indication of the potential change in light penetration into the lake surface were available in the form of Secchi depth readings collected by MPMC, and historic Secchi depths presented in Nidle et al. (1994). Secchi depth is the depth at which a black and white disc lowered into the water column can no longer be seen (Figure 12), and can be correlated with the euphotic zone depth which is the depth to which light intensity is extinguished to 1% of its original intensity (French et al. 1982). Based on paired measurements collected in Quesnel Lake, Secchi depth ranges from similar to or half the euphotic zone depth as determined using a light meter (Nidle et al. 1994).

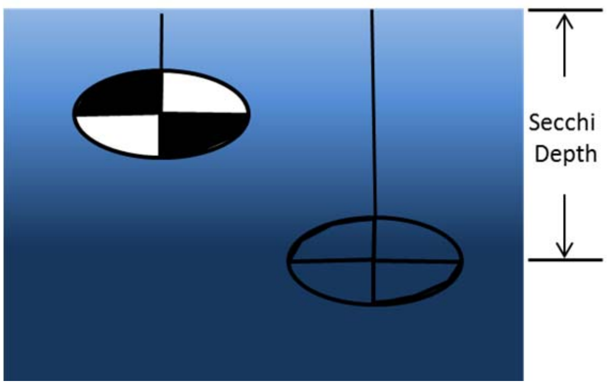

Figure 12: Illustration of Secchi Depth

Secchi depth was variable in the West Arm between sampling events but did not appear to be directly correlated with turbidity except during lake-turnover in the fall (Figure 13). Moreover, the relationship between Secchi depth and turbidity appeared to be similar between the West Arm of the West Basin (exposed) and the lake east of Cariboo Island (reference) where Secchi depth varied from between 3 and 11 m when turbidity was <1 NTU. Transient seiche[2] events resulted in the flow of water from the West Arm eastward over the sill at Cariboo Island into the main body of lake and the introduction of suspended sediment (Tetra Tech EBA 2015b) which could have influenced the Secchi depth in the main body of the lake. However, turbidity east of Cariboo Island was observed to be <1 NTU and most stations and sampling depths based on the MPMC dataset. Secchi depth at some stations was shallower during some sampling events than observed in 1985 to 1990, 2003 and 2004 in which whole-lake averages ranged from 8.8 to 10.2 m (Hume et al. 2005; Nidle et al. 1994).

[2] A seiche is a type of long-wavelength wave that occurs as a result of some disturbance within waterbody that is relatively closed-off from the outside environment.

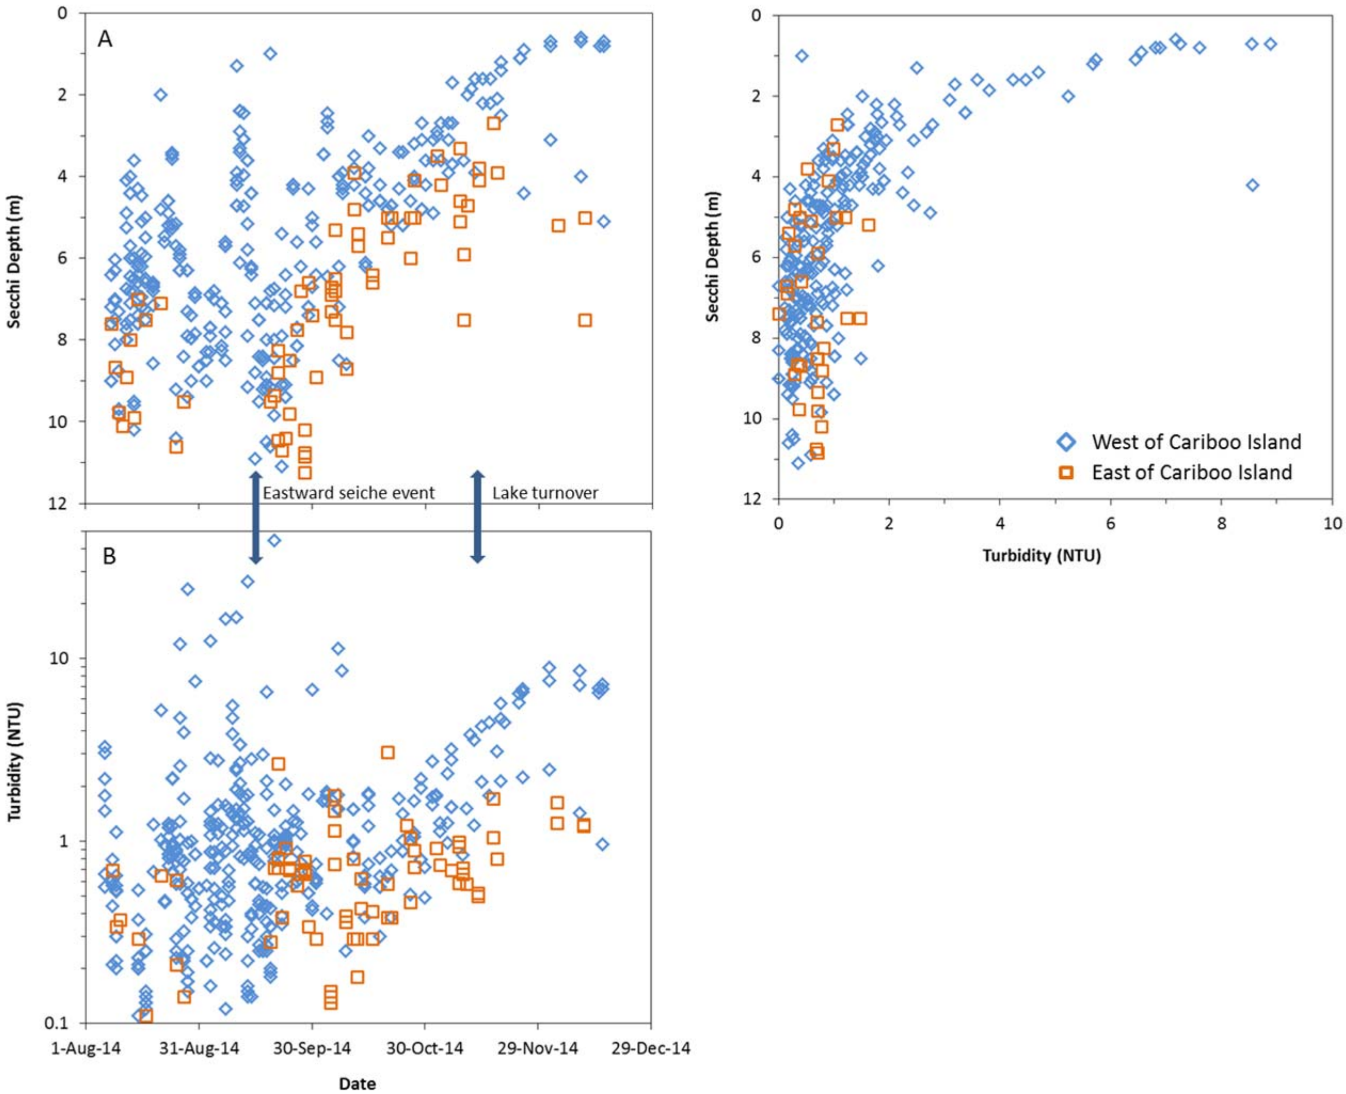

Figure 13: Temporal and spatial variability in Secchi depth (A) and turbidity in the upper 20 m of the water column (B), and Secchi Depth versus Turbidity (C) in the West Arm of the West Basin (West of Cariboo Island; 16 stations) compared to the Middle Arm (East of Cariboo Island; 10 stations) of Quesnel Lake

Lloyd et al. (1987) found that the depth of light penetration (as euphotic zone depth) could be correlated with fish production, thus a potential tool to quantify lost productivity is to compare the euphotic zone volume of the water column before and after the event. Euphotic zone depth was not measured directly in the post-event monitoring program. As discussed above, paired Secchi and euphotic zone depth data were collected by Nidle et al. (1994); however, the relationship between the two measures of light penetration is variable and estimating euphotic zone depth from the post-event Secchi depth data could result in a ±100% error and thus an unreliable prediction of change. Moreover, Lloyd et al. (1987) also observed that an increase in turbidity won't necessarily affect productivity through decreased light penetration if there is a nutrient limitation, which there is in Quesnel

Lake. Thus, it is preferable to assess direct measures of productivity such as chlorophyll *a*, a photosynthetic pigment in attached algae and phytoplankton that can be used as a surrogate for biomass or primary productivity.

Chlorophyll *a* concentrations were available for samples collected from the open-water zone of Quesnel Lake in early and mid-September following the event (Figure 14). Chlorophyll *a* in September 2004 (Hume et al. 2005) was similar to that observed post-event, and in September of 1985 to 1990 (Nidle et al. 1994) was higher than observed post-event. This natural variability in chlorophyll *a* concentration confounds the ability to use historical data to assess the potential for effect and a same-season comparison to reference conditions is preferable. Based on a visual assessment of the chlorophyll *a* time and depth series, biomass in the West Arm was similar to that in the lake east of Cariboo Island. This is not unexpected because of the lag time between the input of phosphorus and the measurement of chlorophyll *a* concentrations. The net growth of phytoplankton is controlled by zooplankton grazing (Huovinen et al. 1999) and the conversion of phytoplankton into fish production is relatively efficient in oligotrophic lakes (Downing et al. 1990). Phytoplankton biomass resulting from the phosphorus input may therefore have been rapidly converted into zooplankton and then fish biomass. The potential change in juvenile Sockeye Salmon biomass is discussed in Section 4.2.4.

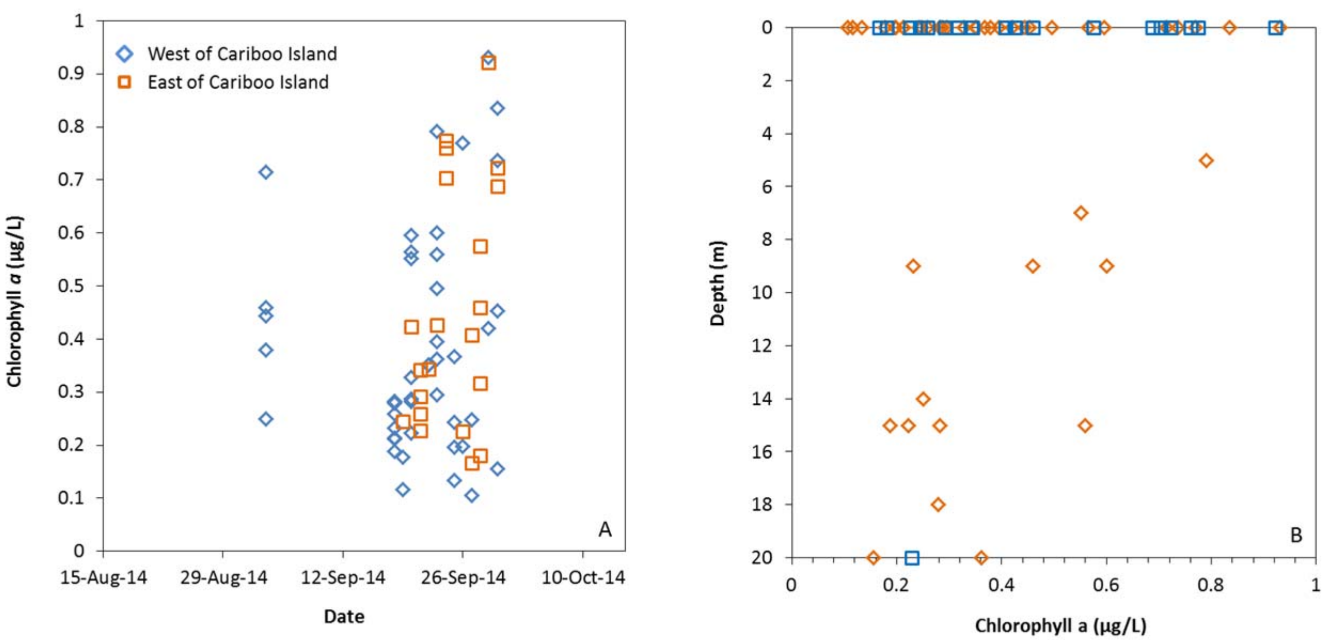

Figure 14: Temporal and Spatial Variability in Chlorophyll a Concentration in Shallow (0 to 20 m) Water in the West Arm of the West Basin (West of Cariboo Island; 11 stations) Compared to the Middle Arm (East of Cariboo Island; 7 Stations) of Quesnel Lake by (A) Sampling Date and (B) Depth

4.2.2.3 Zooplankton Productivity

Minnow (2015b) reported the findings of toxicity testing using two daphnid zooplankton species:

- 48-h acute lethality to *Daphnia magna*; and
- 7-d survival and reproduction of *Ceriodaphnia dubia*.

Water from Quesnel Lake was not acutely toxic to *Daphnia magna* and survival of *Ceriodaphnia dubia* was also not impaired. There were observations of impaired reproduction in *C. dubia* exposed to a small number of turbid deep water samples from Quesnel Lake. The observed effects were not considered by Minnow to be related to metal concentrations (the *Ceriodaphnia* test is known to exhibit false positive results [USEPA 2002]); Minnow (2015b) recommended confirmatory resampling and retesting to verify the observed responses and examine potential causes. The re-testing in samples collected by MPMC indicated that reproductive effects occurred in unfiltered samples whereas no toxicity was observed for the corresponding filtered samples (discussed further in Golder 2015). This suggested that exposure to suspended particulate matter in the samples may have resulted in a reproductive test response in this sensitive invertebrate.

Levy (1990) found that the zooplankton community in Quesnel Lake were non-migratory and located throughout the top 25 to 30 m of the water column. Morton and Williams (1990) further delineated seasonal zooplankton distribution to 75% standing biomass in the top 10 m of the water column when a well-established thermocline was in place (e.g., in August), and 75% standing biomass in the top 25 m of the water column after the thermocline started to weaken (i.e., in October). This zooplankton distribution is an important consideration in the evaluation of the potential reduction in zooplankton productivity as a result of the event.

A further consideration in the assessment of zooplankton productivity is which part of the community is important to CRA fisheries. Based on an evaluation of stomach contents, juvenile Sockeye Salmon preferentially consumed the calanoid copepod *Leptodiaptomus* during the early (May-June) shore-oriented migration of the fish from their natal streams (Morton and Williams 1990). In June, the fish migrate offshore and their prey consumption shifted to the cladoceran *Daphnia*. Other fish that may have been consuming crustacean zooplankton at the time of the event were Rainbow Trout, Lake Trout, and some forage fish species.

Depth-integrated (surface to 30 m) samples of zooplankton were collected by the University of Northern British Columbia (UNBC) approximately weekly between 5 September and 6 November, 2014 (S. Albers, pers. comm.) and a taxonomy dataset (identification of species and enumeration) was provided for use in this report. Methods regarding taxonomic identification and data processing were not provided. Due to differences in resolution of taxonomic identification as well as units[3], the zooplankton abundance and biomass data were not compared to pre-event data presented in Hume et al. (2005) and MacLellan et al. (1993). The samples were collected at one exposed area called Hazeltine (in the West Arm west of Cariboo Island) and at two reference areas, Horsefly (near the Horsefly River) and Junction (in the Main Basin where the east and north arms meet).

[3] For example, areal [value/m^2] versus volumetric [value/m^3] units and presentation on a dry- versus wet-weight basis used for the 2014 samples versus pre-event sampling. Insufficient information regarding methods was available to convert data to a common unit.

Total zooplankton abundance and biomass was lower at Hazeltine than at Junction for all sampling events undertaken by UNBC and declined at a similar rate among stations between mid-September and October of 2014 (Figure 15), as would be expected for the generalized model of productivity shown in Figure 7. Conversely, total abundance and biomass were higher at Hazeltine than at Horsefly (east of Cariboo Island) until mid-October and then lower than at Horsefly at the end of October. At all three stations, the zooplankton community was comprised of a relatively higher proportion of copepods than cladocerans. When cladocerans (e.g., *Daphnia*) are considered separately, abundance and biomass were similar among the three stations except for the first sampling event at the beginning of September at which time *Daphnia* abundance was notably higher at Junction than Hazeltine.

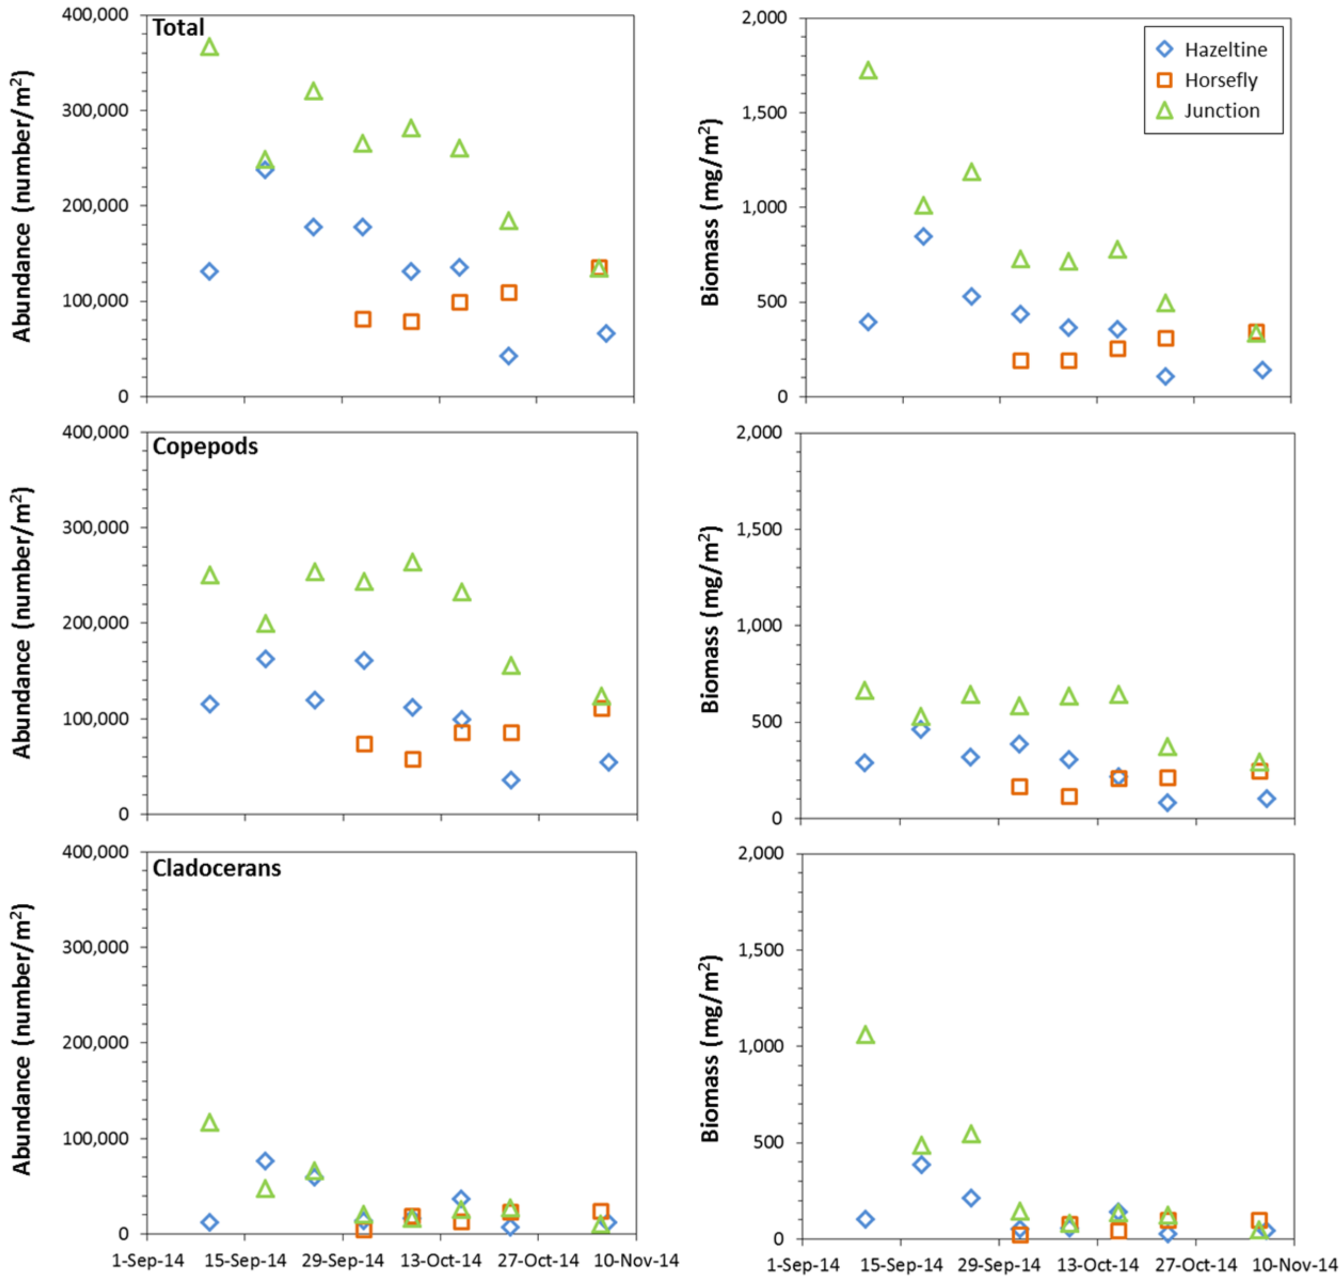

Figure 15: Spatial and Temporal Variability in Zooplankton Abundance and Biomass from Composite, Depth-integrated Samples Collected in the Exposed (Hazeltine) and Reference (Horsefly, Junction) Areas of Quesnel Lake Following the Tailings Dam Failure (Data Courtesy of UNBC)

Turbidity has been observed to affect the ability of zooplankton to consume/utilize phytoplankton, survive and reproduce (Edmundson and Koenings 1986; Levine et al. 2005). For example, Levine et al. (2005) found that induced turbidity levels of 2 to 10 NTU reduced clearance of phytoplankton by 70 to 100% and resulted in reduction in the growth and abundance of *Daphnia* and a calanoid copepod. Turbidity in the top 10 m of the water column that *Daphnia* tend to occupy in summer was in the range of 2 to 10 NTU, thus it was possible that zooplankton feeding rates were affected. However, as noted in Section 4.2.2.2 the conversion of phytoplankton into fish production is relatively efficient in oligotrophic lakes (Downing et al. 1990) and therefore, a higher zooplankton biomass resulting from the phosphorus input discussed in Section 4.2.2.1 would likely have been rapidly converted into fish biomass (the potential change in juvenile Sockeye Salmon biomass is discussed in Section 4.2.4).

Edmundson and Koenings (1986) observed that the *Daphnia* component of a glacial lake zooplankton community was less tolerant of induced turbidity (at 45 NTU) and had higher rates of mortality and lower rates of reproduction than did copepods and rotifers. A shift in cladocerans versus copepods was not observed in the zooplankton data for Quesnel Lake collected post-event; however, the zooplankton samples were collected commencing one month after the event, and changes in zooplankton abundance in either direction would not necessarily have been detected.

4.2.2.4 Benthic Invertebrates/Emerging Insects

Production of benthic invertebrates and emerging insects was disrupted at the mouth of Hazeltine Creek in the littoral zone and immediately adjacent lakebed due to the alteration of the habitat; the area of alteration is presented in Section 4.1.3. Acute mortality of benthic invertebrates also occurs at similar TSS concentrations reported to affect fish (720-51,000 mg/L; CCME 1999). Thus, it is possible that elevated TSS immediately following the TSF dam affected nearby areas not in the immediate area of alteration; however, data are unavailable to quantify this effect.

Based on the findings of Minnow (2015a), the disruption in production of benthic invertebrates was likely temporary. In both the littoral and profundal zone of the West Arm, the sediments collected one month post-event contained benthic invertebrates, including chironomids which are a preferred food item for several CRA fish species (e.g., Rainbow Trout). The abundance and diversity of organisms in the West Arm sediments was typically lower than that of reference areas at the time of sampling; however, the community is expected to continue to re-establish. Although early sampling suggests that some recovery may have begun, benthos sampling subsequent to deposition and settling of the sediments is necessary to confirm if the impact is of a transient nature.

4.2.3 Food Supply – Quality

UNBC collected zooplankton samples from three locations on Quesnel Lake concurrent with the taxonomy and had them analyzed for a suite of metals (S. Albers, pers. comm.). The samples were collected at one exposed area called Hazeltine (in the West Arm west of Cariboo Island) and at two reference areas, Horsefly (near the Horsefly River) and Junction (in the Main Basin where the east and north arms meet). Depth-integrated (surface to 30 m) samples were collected approximately weekly between 5 September and 6 November, 2014. Multiple tows were collected to generate a composite with sufficient biomass for analysis. One replicate sample was collected from Junction on 2 October 2014 for quality control purposes. The *BC Field Sampling Manual* (BC MoE 2013) recommends that the relative percent difference (RPD) between replicate samples be calculated where concentrations are greater than five times the detection limit (DL)[4]. An RPD of >20% indicates a notable difference between samples. Where the RPD could be calculated (i.e., values were >five times DL), all the parameters analyzed had results <20%, except for lead and chromium which exhibited higher variability, and overall the zooplankton tissue chemistry were considered reliable for the purposes of this assessment.

Figure 16 illustrates the temporal and spatial variability in copper, which was considered a parameter of concern based on water column concentrations, and selenium, mercury and arsenic, parameters of potential concern because their primary mode of toxicity is via dietary uptake versus direct toxicity from a water exposure, or can biomagnify (e.g., mercury) in the food chain.

- **Copper** concentrations appeared to increase over time at Hazeltine (exposed) and were higher than at the other two stations (reference) between October and December. However, copper does not biomagnify and concentrations of copper are lower than those that had no adverse effect on Rainbow Trout (Miller et al. 1993).
- **Selenium** concentrations were below the BC dietary guideline for tissue consumption by fish (BC MoE 2014) for all samples collected from Hazeltine and Horsefly. The highest concentrations were observed at Junction and exceeded the BC dietary tissue guideline.
- **Mercury** concentrations were variable at all three stations, ranging from non-detectable to less than 0.1 mg/kg dw. The highest concentrations were observed in zooplankton from Junction.
- **Arsenic** concentrations appear to increase between September and November 2014 at Hazeltine; however, they were all lower than the highest concentrations observed at Junction in September and were similar to concentrations observed at Horsefly and Junction in October through November.

Overall, the event did not appear to result in a biologically significant change in arsenic, mercury or selenium concentrations in zooplankton from the West Arm of the West Basin of Quesnel Lake relative to concentrations observed in the lake east of Cariboo Island. The change in copper concentrations at Hazeltine may have been in response to copper associated with increasing suspended solids in the water column during lake turn over as small particulates may have been attached to phytoplankton biomass and consumed incidentally. When aquatic invertebrates have ingested sediment particles and gut contents are not cleared prior to whole tissue analysis, actual uptake by the organism can be overestimated (Gillis et al. 2005; Sibley et al. 1997). Nevertheless, and even if the observed concentrations of copper in zooplankton in the West Basin were in the tissue and not just in the gut, these concentrations are lower than dietary no-effect levels for Rainbow Trout (e.g., Miller et al. 1993). As discussed in Section 4.2.1, growth of juvenile Sockeye in the West Basin was higher than that of fish collected in reference areas of the lake and thus consumption of zooplankton from the West Arm does not appear to have affected growth.

[4] Within five times the DL, laboratory results are considered too variable to be representative of the true concentration (BCMoE 2013).

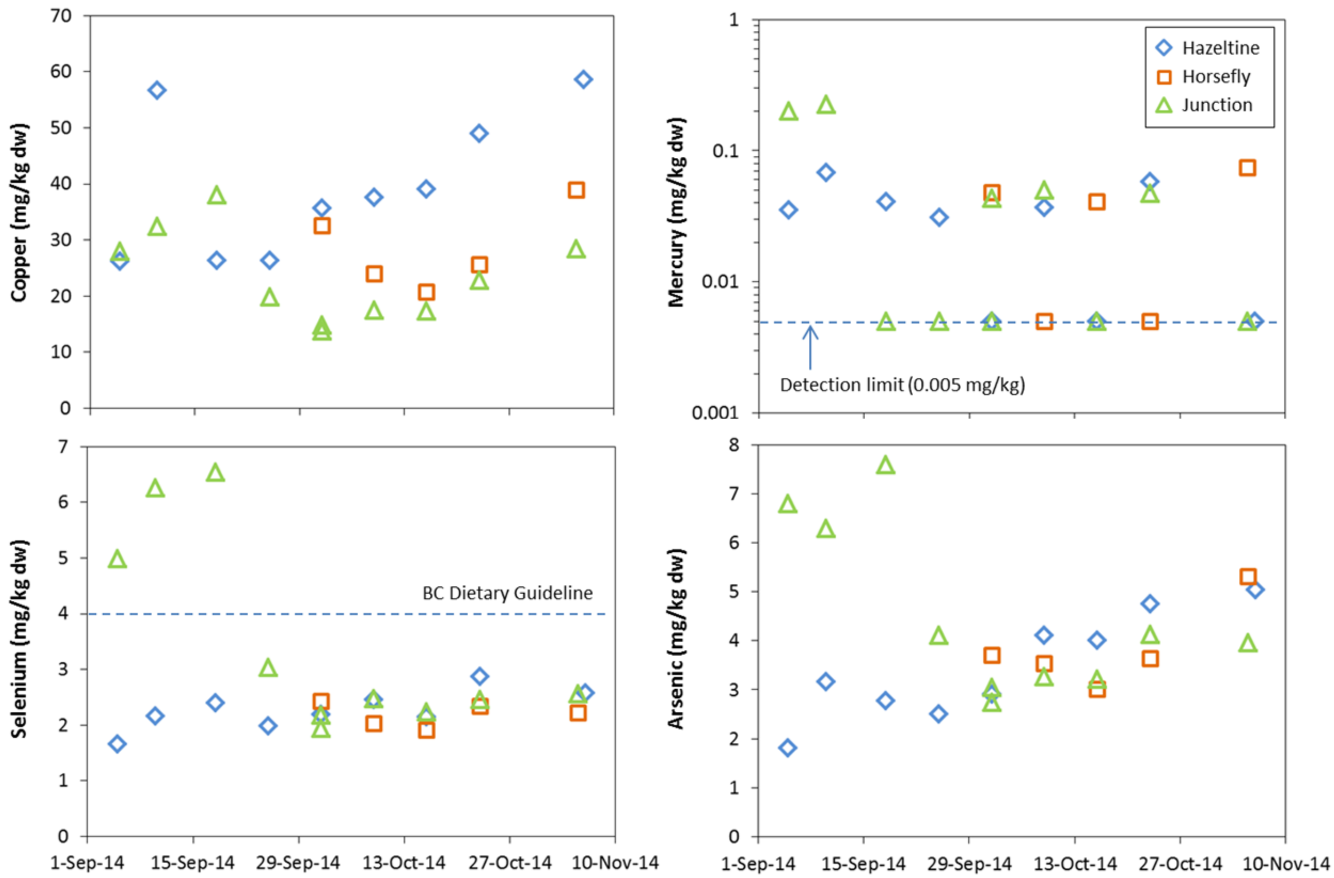

Figure 16: Spatial and Temporal Variability in Zooplankton Tissue Chemistry from Composite, Depth-integrated Samples Collected in the Exposed (Hazeltine) and Reference (Horsefly, Junction) Areas of Quesnel Lake Following the Tailings Dam Failure (Data Courtesy of UNBC)

4.2.4 Food Supply - Efficiency

Foraging efficiency can be affected by increased turbidity via change in feeding rates, reaction distance, prey selection and prey abundance (Bash et al. 2001; Muck 2010; Sigler et al. 1984). The potential for effects on foraging efficiency and food capture is dependent on the species and habitat being occupied, and the ultimate influence on productivity is balanced among food availability, prey capture success, and predator avoidance (De Robertis et al. 2003; Levy 1990; Roberge et al. 2001; Robertson et al. 2006).

Littoral/Nearshore Area

Fish feeding in littoral (i.e., the area less than 6 m deep along the shoreline) and nearshore zones may not have been affected because turbidity was less than 5 to 10 NTU in the top 5 to 10 m of the water column. Moreover, several fish species occupying the littoral zone feed at night or are benthic feeders and therefore do not rely on sight to capture prey (e.g., Northern Pikeminnow; sucker), or are not sensitive to turbidity (e.g., sculpin) (McPhail 2007).

Open-water Area

Shaw and Richardson (2001) found that following pulsed inputs of fine sediments to experimental channels, Rainbow Trout juveniles grew less than control fish, possibly due to increased physiological stress and inability to capture drifting invertebrates. However, these were artificial mesocosms with trout confined to small areas and it appears that these findings cannot be extrapolated to juvenile Sockeye in Quesnel Lake, given that length and weight data collected from Quesnel Lake following the event (Section 4.2.1) show that this species grew considerably.

Rainbow Trout migrate out of the open-water area of Quesnel Lake into the Horsefly and Mitchell Rivers twice a year (Sebastian et al. 2003). The first migration is in spring either to spawn, or to feed on newly emerged Sockeye fry (pre-spawner and non-spawner Rainbow Trout). The second is a “feeding” migration to the same rivers from July to September when age 3 to 5+ and some larger fish preferentially feed on aquatic invertebrates, Sockeye eggs and adult Sockeye carcasses. The TSF dam failure occurred during the timing of the “feeding” migration which may have reduced the number of Rainbow Trout in the West Arm and thus the potential effect of the event on feeding success with the exception of Lower Hazeltine Creek.

In deeper areas of the lake, turbidity was higher, increasing from 10 NTU at the thermocline to >200 NTU at the lakebed (Golder 2015; Petticrew et al. 2015). However, the thermocline was at or below the expected euphotic depth of the lake. Therefore, fish feeding/foraging at these depths would not necessarily be expected to rely on visual cues (for example, adult Burbot feed at night; McPhail 2007) and their efficiency at prey capture may not have been affected although prey density may have.

Benthic Area

Fish species occupying the benthic zone feed at night or are benthic feeders and would not necessarily rely on sight to capture prey (e.g., Burbot, sucker; McPhail 2007). Feeding efficiency may thus not have been affected by increased turbidity. However, in those benthic zones at the bottom of Quesnel Lake, a reduction in food supply would have been expected.

4.2.5 Bioenergetics

Length and weigh data collected by DFO indicated that juvenile Sockeye Salmon captured from the West Arm of the West Basin in September 2014 were larger than Sockeye capture in reference areas of the lake, and were also larger than Sockeye collected from the West Arm in 2013 (Section 4.2.1). Data for other fish species were not available.

4.3 Individual Performance

4.3.1 Stress

Suspended sediment can cause changes in behaviour such as avoidance (Bisson and Bilby 1982; Robertson et al. 2006) and physiological trauma such as gill damage (Birtwell 1999; Muck 2010; Servizi and Martens 1987):

- Avoidance can occur at turbidity levels on the order of 35 to 70 NTU, measured in a laboratory (Bisson and Bilby 1982). In that study, this level of turbidity occurred below the thermocline and thus diel vertical migrations could have been disrupted. Petticrew et al. (2015) reported that fish aggregated in the West

Arm of Quesnel Lake following the TSF dam failure, thus it appears that fish did not necessarily migrate out of the area as Robertson et al. (2006) suggest may occur in response to an increase in turbidity.

- Gill abrasions have been observed at TSS concentrations on the order of hundreds to thousands of mg/L (Birtwell 1999; Servizi and Martens 1987). It is possible that TSS concentrations of this magnitude occurred immediately after the TSF dam failure and immediately adjacent to the mouth of Hazeltine Creek; however, at the stations from which MPMC collected water quality data, TSS concentrations were below 50 mg/L (Figure 8) which is a level at which gill abrasions would not be expected. DFO has submitted preserved samples of juvenile Sockeye for histological analysis. As of the date of this report, results from these analyses were not available.

As discussed in Section 4.2.1, Fathead Minnow and Rainbow Trout exposed to Quesnel Lake water in laboratory toxicity testing and juvenile Sockeye Salmon collected from Quesnel Lake did not fail to grow, which is a potential outcome of the stressors identified above.

Samples of several fish species were collected for analytical chemistry, sampling dates and locations in Quesnel Lake. The data are provided in SNC-Lavalin (2015a) and will be assessed in the future ecological risk assessment.

4.3.2 Olfactory Effects

In natural waters, copper is known to be complexed with a variety of organic and inorganic ligands and thus free copper (Cu^{2+}) is typically present in minor amounts (Allen and Hansen 1996; Bazzi et al. 2002). It is this Cu^{2+} form that is the more toxic form of copper and has greater effect on olfactory organs, which play a role in predator avoidance and homing ability. Table 4 summarizes commonly cited studies on the effects of copper on homing ability of adult salmonids. At hardness levels similar to that observed in Quesnel Lake, field observations of effects on homing occurred at copper concentrations of 10 to 25 µg/L.

Table 4: Studies on Copper and Olfactory Impacts That are Most Commonly Cited

Copper Conc. (µg/L)	Hardness (mg/L)	Exposure Duration	Effect	Source
20	20	Indefinite	Atlantic salmon spawning migrations in the wild interrupted	Sprague et al. (1965) cited in Hecht et al. (2007)
10-25	40	Indefinite	Chinook salmon spawning migrations in the wild apparently disrupted	Mebane (2000)
44	n/a	n/a	90% reduction in selection of home stream by Atlantic salmon	Sutterlin and Gray (1973), cited in Mebane (1994)

Note: n/a - not available

In comparison, dissolved copper concentrations on the order of 2 µg/L or less have been demonstrated in some laboratory behavioural studies to reduce the ability of juvenile salmon to avoid prey (Sandahl et al. 2007). However, there is some disagreement in the scientific community about these findings as other researchers have not been able to reproduce the results at these low levels (Bailey et al. 2015). Moreover, dissolved organic carbon concentrations are often not reported in such studies. Dissolved organic carbon reduces copper effects on olfactory sensory organs, as it reduces copper toxicity. DeForest et al. (2011) indicate that Biotic Ligand Model (BLM)-based water quality criteria for dissolved copper (USEPA 2007) would be protective against olfactory effects in juvenile salmon. This was based on an evaluation of water chemistry data from some 113 watercourses. As an example, DeForest et al. (2011) estimated a BLM-based 20% olfactory effect level concentration (EC20) of 13.1 µg/L for a creek with water chemistry that has similarities to the chemistry of Quesnel Lake (i.e., the creek had the following characteristics: pH = 8.2, hardness = 80 mg/L, dissolved organic carbon = 1.1 mg/L). This estimated concentration is higher than both the acute (8.1 µg/L) and chronic (5.0 µg/L) BLM-based USEPA water quality criteria, suggesting that the BLM-based criteria protect against olfactory impacts.

The highest concentration of dissolved copper measured in MPMC's monitoring program was 9.1 µg/L, from a sample location near the outlet of Hazeltine Creek and at 50 m depth; the maximum dissolved copper concentration in water to 20 m depth was 3.9 µg/L. This is a conservative characterization of the concentration that salmon would be exposed to because the average concentrations, representing the majority of the water chemistry, are lower. The average concentration at depth (>20 m) was 4.7 µg/L and in shallower water (<20 m) was 1.3 µg/L. In Quesnel Lake near the Town of Likely, the average dissolved copper concentration was 0.76 µg/L and in the Quesnel River was 1.1 µg/L. More recent water chemistry data indicate that copper concentrations have since decreased over time (Golder 2015).

When compared to the literature thresholds for olfactory impairment, these concentrations are below the thresholds at which olfactory effects in salmon would be expected. This is also true for the maximum measured concentration of dissolved copper (9.1 µg/L) which is below the reported olfactory thresholds for similar hardness and dissolved carbon concentrations. Therefore, based on the water chemistry data from Quesnel Lake and Quesnel River, impacts on fish migration through olfactory impairment and lost "homing" ability were unlikely. This is supported by the 2014 Sockeye Salmon escapement summary by the Pacific Salmon Commission for Quesnel Lake which indicates that Sockeye returned to spawning areas at relatively high numbers. These returns do not reflect the potential for effects on juvenile salmon; however, based on what is known about copper bioavailability as a result of the event (as summarized in Golder 2015), and the effects thresholds discussed above, effects on juveniles are not expected.

4.3.3 Disease

The physiological stress associated with exposure to elevated concentrations of TSS may reduce the ability of a fish to resist disease at TSS concentrations of 100 to 300 mg/L (citations in Lloyd 1987) or to tolerate exposure to pentachlorophenol at TSS concentrations > 100 mg/L (Birtwell 1999; McLeay et al. 1987). It is possible that TSS concentrations of this magnitude occurred immediately after the TSF dam failure, and immediately adjacent to the mouth of Hazeltine Creek; however, at the stations from which MPMC collected water quality data, TSS concentrations were below 50 mg/L and thus an increased incidence of disease would not be expected (Figure

8). Incidence of disease, such as that induced by gill abrasions would be identifiable in the historological study being carried out by DFO.

As discussed in Section 4.2.1, Fathead Minnow and Rainbow Trout exposed to Quesnel Lake water in laboratory toxicity testing and juvenile Sockeye Salmon collected from Quesnel Lake did not fail to grow, which is a potential outcome of the stressors identified above.

4.4 Migration

Changes in migration were not considered a potential effect to productivity. The only migratory corridor blocked was into Hazeltine Creek for which habitat alteration has been accounted in SNC-Lavalin (2015c).

4.5 Reproduction

4.5.1 Adult Maturation and Reproduction

A full reproductive cycle has not yet occurred for several fish such as Sockeye Salmon and therefore cannot be assessed at this time. However, water quality conditions and toxicity testing results do not indicate that such effects would be likely on sockeye or other species.

4.5.2 Density-independent Reproductive Success (Spawning Habitat Quality)

A change in spawning habitat quality for Sockeye Salmon is unlikely to have occurred in the lake as lake spawning has not been observed in the West Arm west of Cariboo Island. For fish species that spawn in the littoral zone, there may have been a temporary loss of use of the area, depending on the timing of spawning. Fish species that migrate to streams and rivers (including the seasonal channel in the Hazeltine fan area) to spawn are addressed in the FFHIA (SNC-Lavalin 2015c). Sockeye spawning has been recorded in Lower Hazeltine Creek; however, the brood year returning in 2014 was expected to be minimal (T. Whitehouse, DFO, pers. comm.).

4.5.3 Density-dependent Reproductive Success (Spawning Habitat Quantity)

A change in spawning habitat quantity for Sockeye Salmon is unlikely to have occurred in the lake as lake spawning has not been observed in the West Arm east of Cariboo Island. For fish species that spawn in the littoral zone, there may have been a temporary loss of use of the area, depending on the timing of spawning. Fish species that migrate to streams and rivers (including the seasonal channel in the Hazeltine fan area) to spawn are addressed in the FFHIA (SNC-Lavalin 2015c). Sockeye spawning has been recorded in Lower Hazeltine Creek; however, the brood year returning in 2014 was expected to be minimal (T. Whitehouse, DFO, pers. comm.).

4.6 Summary of Effects on Fish Productivity

4.6.1 Productivity of Fish Associated with the Littoral Zone and Benthic Habitat

The event resulted in the alteration of littoral habitat at the mouth of Hazeltine Creek, resulting in the displacement or potential (unconfirmed) loss of fish in the area (Table 5). Debris was also deposited on the lakebed in the profundal area, which resulted in a change in the benthic habitat and a potential disruption in the benthic invertebrate community. The impact on the bed of Quesnel Lake continues to be studied. Although early sampling suggests that some recovery may have begun, benthos sampling subsequent to deposition and settling of the sediments is necessary to confirm if the impact is of a transient nature. Post-event toxicity testing indicated that Quesnel Lake water did not affect survival or growth of fish or growth of plant test species.

4.6.2 Productivity of Fish Associated with Open-water Habitat that Feed on Emerging Insects

Production of emerging insects was disrupted on the lakebed in a way similar to that discussed in Section 4.6.1 as a result of the disruption to benthic habitat (Table 6). Although early sampling suggests that some recovery may have begun, benthos sampling subsequent to deposition and settling of the sediments is necessary to confirm if the impact is of a transient nature. Post-event toxicity testing indicated that Quesnel Lake water did not affect survival or growth of fish or growth of plant test species.

4.6.3 Productivity of Fish Associated with Open-water Habitat that Feed on Crustacean Zooplankton

Post-event toxicity testing indicated that Quesnel Lake water did not affect survival or growth of fish, survival or growth of daphnid zooplankton, or growth of plant test species. The literature indicates that the direction of change in primary productivity as a result of introduction of suspended sediments to a lake depends on whether the phytoplankton are light limited or nutrient limited. The preliminary information available at this time suggest that there was an influx of phosphorus into Quesnel Lake and although changes in phytoplankton and zooplankton biomass were not observed, juvenile Sockeye Salmon collected west of Cariboo Island were larger than those from the lake east of Cariboo Island (Table 7). The absence of an observed increase in either phytoplankton or zooplankton abundance may reflect grazing/predation, which may in turn be reflected in the larger and possibly more numerous juvenile Sockeye observed in DFO's data compared to previous years.

Table 5 Summary of Effects on Productivity of Littoral Zone and Benthic Habitat

Component of Productivity	Sub-component	Mechanism	Potential Effect on Productivity
Survival	Density independent mortality	Direct mortality	■ Possible, but not quantifiable as no dead fish were observed. Fish may also have been displaced.
		Exceedance of environmental tolerances	■ TSS concentrations could have been high enough in the littoral and benthic zones during and immediately following the event to cause lethal conditions; however, the post-event water quality monitoring program did not identify concentrations above 50 mg/L. ■ Post-event toxicity testing indicated that Quesnel Lake water did not affect survival of juvenile Rainbow Trout or to Fathead Minnow (representative of forage fish that may occupy the littoral zone).
	Reduced habitat quality or quantity	Habitat supply limitation	■ A littoral area of approximately 94,400 m^2 was altered. ■ A benthic area of approximately 1.81 km^2 below the 100 m contour was altered.
Growth	Fish Growth	-	■ Growth of Fathead Minnow was not affected in laboratory water toxicity tests. ■ No information was available regarding growth of fish occupying the littoral or benthic zones.
	Food supply	Quantity	■ Post-event toxicity testing indicated that the growth of aquatic vascular plant and algal test organisms was not impaired. ■ The literature indicates that the response of productivity as a result of an introduction of suspended solids can be offset by a concurrent input of nutrients. The event resulted in a pulse of phosphorus and organic carbon to the lake; however, no data were available to evaluate the overall potential change to quantity of planktonic food in the littoral zone. ■ In sediment toxicity tests, organic carbon was low in many samples and was associated with poor performance in growth or survival of test organisms. ■ Production of benthic invertebrates and emerging insects was disrupted at the mouth of Hazeltine Creek in the littoral zone and the adjacent lakebed due to the alteration of the habitat. One month following the event, these areas were being recolonized.
		Quality	■ No data were available regarding the potential uptake of metals in food organisms.

Component of Productivity	Sub-component	Mechanism	Potential Effect on Productivity
Growth cont.	Efficiency	Foraging	■ It is possible that foraging ability was affected for species reliant on sight. Several fish species occupying the littoral and benthic zones are not visual feeders or are tolerant of turbidity.
		Bioenergetics	■ No data were available regarding a potential change in energy conversion.
Individual performance	Stress	Suboptimal environmental conditions	■ Suspended sediments can cause change in behaviour; however, turbidity in the upper water column was lower than turbidity observed to cause such effects.
	Olfactory effects	Suboptimal environmental conditions	■ Copper concentrations were lower than those observed to cause effects.
	Disease	Infection	■ TSS concentrations were lower than those reported in the literature to reduce the ability of a fish to resist disease.
Migration	-	Disruption of normal behaviour	■ NA
Reproduction	Adult maturation	Suboptimal environmental conditions	■ No information available.
	Density-independent reproductive success	Spawning habitat quality	■ There may have been a temporary loss of use of littoral and benthic habitat altered as a result of the event.
	Density-dependent reproductive success	Spawning habitat quantity	■ There may have been a temporary loss of use of littoral and benthic habitat altered as a result of the event.

Notes:
NA – not applicable; TSS – total suspended solids

Table 6 Summary of Effects on Productivity of Open-water Habitat and Fish that Feed on Emerging Insects

Component of Productivity	Sub-component	Mechanism	Potential Effect on Productivity
Survival	Density independent mortality	Direct mortality	■ Possible, but not quantifiable as no dead fish were observed. Fish may also have been displaced.
		Exceedance of environmental tolerances	■ TSS concentrations could have been high enough in limnetic zone adjacent to the Hazeltine delta during and immediately following the event to cause lethal conditions; however, the post-event water quality monitoring program did not identify concentrations above 50 mg/L. ■ Post-event toxicity testing indicated that Quesnel Lake water was not toxic to juvenile Rainbow Trout
	Reduced habitat quality or quantity	Habitat supply limitation	■ NA
Growth	Fish growth	-	■ No information was available for Rainbow Trout or Mountain Whitefish
	Food supply	Quantity	■ In sediment toxicity tests, organic carbon was low in many samples and was associated with poor performance in growth or survival of test organisms. ■ Production of emerging insects was disrupted on lakebed due to the alteration of the habitat. One month following the event, these areas were being recolonized.
		Quality	■ No information was available regarding potential change in food quality.
	Efficiency	Foraging	■ It is possible that foraging ability was affected for species reliant on sight. Rainbow Trout undergo a feeding migration to rivers from July to September and thus may not have been present during the event.
		Bioenergetics	■ No data were available to evaluate energy conversion.

Component of Productivity	Sub-component	Mechanism	Potential Effect on Productivity
Individual performance	Stress	Suboptimal environmental conditions	■ Suspended sediments can cause change in behaviour; however, turbidity in the upper water column was lower than turbidity observed to cause such effects. ■ Post-event toxicity testing indicated that Rainbow Trout did not fail to grow, which is a potential outcome of stress.
	Olfactory effects	Suboptimal environmental conditions	■ Copper concentrations were lower than those observed to cause effects.
	Disease	Infection	■ TSS concentrations were lower than those reported in the literature to reduce the ability of a fish to resist disease. ■ Post-event toxicity testing indicated that Rainbow Trout did not fail to grow, which is a potential outcome of stress.
Migration	-	Disruption of normal behaviour	■ NA
Reproduction	Adult maturation	Suboptimal environmental conditions	■ No information available.
	Density-independent reproductive success	Spawning habitat quality	■ NA; spawning occurs in streams and rivers.
	Density-dependent reproductive success	Spawning habitat quantity	■ NA; spawning occurs in streams and rivers.

Notes:
NA – not applicable; TSS – total suspended solids

Table 7 Summary of Effects on Productivity of Open-water Habitat and Fish that Feed on Crustacean Zooplankton

Component of Productivity	Sub-component	Mechanism	Potential Effect on Productivity
Survival	Density independent mortality	Direct mortality	■ Possible, but not quantifiable as no dead fish were observed. Fish may also have been displaced.
		Exceedance of environmental tolerances	■ TSS concentrations could have been high enough in limnetic zone adjacent to the Hazeltine delta during and immediately following the event to cause lethal conditions; however, the post-event water quality monitoring program did not identify concentrations above 50 mg/L. ■ Post-event toxicity testing indicated that Quesnel Lake water was not toxic to juvenile Rainbow Trout
	Reduced habitat quality or quantity	Habitat supply limitation	■ NA
Growth	Fish growth	-	■ Post-event toxicity testing indicated that Rainbow Trout did not fail to grow in Quesnel Lake water. ■ Juvenile Sockeye Salmon captured from the West Arm of the West Basin in September 2014 were larger than Sockeye capture in reference areas of the lake, and were also larger than Sockeye collected from the West Arm in 2013.
	Food supply	Quantity	■ Post-event toxicity testing indicated there was no impairment in growth of an algal test organism. ■ Lake water was not toxic to daphnid zooplankton and did not affect reproduction ■ The literature indicates that the response of productivity as a result of an introduction of suspended solids can be offset by a concurrent input of nutrients. The event resulted in a pulse of phosphorus to the lake. A resulting increase in primary and zooplankton productivity was not observed; however, the conversion of phytoplankton into fish production is relatively efficient in oligotrophic lakes.
		Quality	■ The event did not appear to result in a change in arsenic, mercury or selenium concentrations in zooplankton from the West Arm. Conversely, copper concentrations increased, but this may have been related to the ingestion of suspended particles, which can result in an overestimate of uptake into tissues. Moreover, the tissue concentrations were lower than no-effects concentrations for Rainbow Trout.

Component of Productivity	Sub-component	Mechanism	Potential Effect on Productivity
Growth cont.	Efficiency	Foraging	■ Inputs of suspended sediment can affect the prey capture success of visual feeders; however, this is not supported by juvenile Sockeye length and weight data.
		Bioenergetics	■ Juvenile Sockeye Salmon growth data indicate efficient conversion of energy from zooplankton.
Individual performance	Stress	Suboptimal environmental conditions	■ Suspended sediments can cause change in behaviour; however, turbidity in the upper water column was lower than turbidity observed to cause such effects. ■ Rainbow Trout exposed to Quesnel Lake water in laboratory toxicity testing and juvenile Sockeye Salmon collected from Quesnel Lake did not fail to grow, which is a potential outcome of stress.
	Olfactory effects	Suboptimal environmental conditions	■ Copper concentrations were lower than those observed to cause effects. ■ Adult Sockeye Salmon were observed to return at relatively high numbers in September 2014.
	Disease	Infection	■ TSS concentrations were lower than those reported in the literature to reduce the ability of a fish to resist disease. ■ Rainbow Trout exposed to Quesnel Lake water in laboratory toxicity testing and juvenile Sockeye Salmon collected from Quesnel Lake did not fail to grow, which is a potential outcome of stress.
Migration	-	Disruption of normal behaviour	■ NA
Reproduction	Adult maturation	Suboptimal environmental conditions	■ No information available at the time of writing.
	Density-independent reproductive success	Spawning habitat quality	■ NA; potential spawning in the Hazeltine fan area addressed in SNC-Lavalin (2015c) ■ Primary spawning areas are in other streams and rivers or lakeshore areas in the eastern part of the lake.

Component of Productivity	Sub-component	Mechanism	Potential Effect on Productivity
Reproduction cont.	Density-dependent reproductive success	Spawning habitat quantity	■ NA; potential spawning in the Hazeltine fan area addressed in SNC-Lavalin (2015c) ■ Primary spawning areas are in other streams and rivers or lakeshore areas in the eastern part of the lake.

Notes:
NA – not applicable; TSS – total suspended solids

5.0 POLLEY LAKE IMPACT ASSESSMENT

5.1 Survival

5.1.1 Direct Mortality of Fish

It is possible that fish occupying the littoral zone at the outlet to Hazeltine Creek were entrained in the debris or they may have been displaced in advance of the debris reaching the lake. However, dead fish were not observed and this potential effect on productivity cannot be quantified.

5.1.2 Exceedance of Environmental Tolerances

The on-going monitoring program reported TSS levels less than those observed to cause acute lethality (Figure 17) and laboratory toxicity testing with Rainbow Trout (96-h LC50) and Fathead Minnow (7-day survival and growth) indicated that water from Polley Lake was not lethal to these fish species (Minnow 2015b). No dead fish were observed and this potential effect on productivity cannot be quantified.

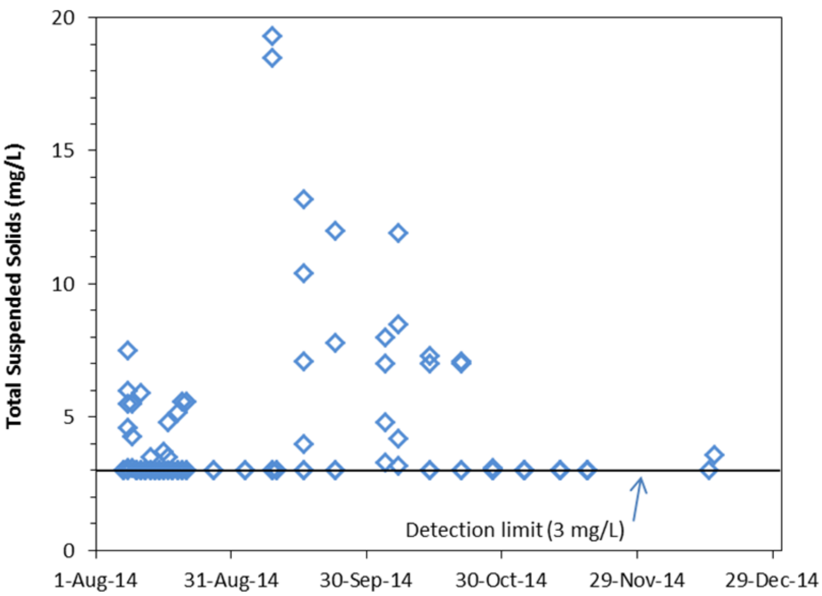

Figure 17: Temporal Variability in Total Suspended Solids Concentration in Polley Lake

5.1.3 Habitat Quantity or Quality

A portion of the south end of Polley Lake near the outflow to Hazeltine Creek was filled with a mixture of tailings, embankment material, and eroded native material from the breach that plugged the outlet of Polley Lake (SNC-Lavalin 2015b). There has been no quantitative estimate of the spatial extent of this material coverage and the change in bathymetry cannot be reliably estimated because of a lack of reliable pre-event data. The effect to productivity is expected to be temporary as the littoral area will become established.

The physico-chemical quality and toxicity of lake sediments were addressed by Minnow (2015a). As observed for Quesnel Lake (Section 4.1.3), the area affected by the event had a lower total organic carbon content, which may have contributed to a modest effect on growth in the midge (*Chironomus dilutus*) test observed in toxicity testing. Low organic carbon can be expected to result in decreased growth because it reflects lower food supply.

5.2 Growth

5.2.1 Fish Growth

Growth of Fathead Minnow was not affected in the 7-day survival and growth tests conducted in water from Polley Lake (Minnow 2015b).

Lirette (2015a) surveyed the age structure and body condition of Rainbow Trout and Longnose Sucker in Polley Lake on September 23-24, 2014 using sinking and floating gill nets set at maximum depths of 7.6 and 9.5 m in the littoral zone at the north end of the lake. The study design was based on earlier studies carried out so that comparisons could be made. A total of 144 Rainbow Trout, 140 Longnose Suckers, and one Redside Shiner were captured in the nets. Mean condition factor (CF or *K*; calculated based on length and weight) for rainbow trout was higher in 2014 than in 2012 and slightly lower for Longnose Sucker in 2014 than in 2012 (Table 8). Lirette (2015a) noted that higher condition factors in the past (i.e., 1973 and 1995) may have been due to increased harvesting of Rainbow Trout, which reduces fish density and competition for resources. The condition of these fish species did not appear to have been affected within seven weeks of the event, which corresponded to the period of highest turbidity at depth.

Table 8: Summary of Fish Age and Condition for Polley Lake

Species	Year	Age range	Mean condition factor [(a)]
Rainbow trout	1973	-	1.341
	1990	2^+ to 6^+	-
	1995	3^+ to 4^+	1.253
	2009/2010	3^+ to 6^+	-
	2012	-	0.993
	2014	1^+ to 6^+	1.103
Longnose sucker	1995	-	1.454
	2009/2010	5^+ to 10^+	-
	2012	-	1.354
	2014	1^+ to 13^+	1.239

Notes:
Source: Lirette (2015a)
(a) Condition factor (CF or '*K*') is calculated from the relationship between fish length and weight. Lirette (2015a) used the following equation: $100\ x\ \frac{(weight\ [g])}{(fork\ length\ [cm])^3}$

5.2.2 Food Supply - Quantity

5.2.2.1 Nutrient Inputs

Following the event, surface measurements of total phosphorus were higher than applicable WQGs, but the trophic status of Polley Lake did not change and remained mesotrophic/eutrophic post-event (Figure 11). At depth, mean total phosphorus concentrations were higher; however, a large proportion of the total phosphorus was associated with the particulate fraction, and mean dissolved phosphorus concentrations were similar to pre-event concentrations. Although there was a change in total phosphorus concentrations in Polley Lake, overall there did not appear to be a discernable change in the concentration of phosphorus available to plant life, due to the event. There appeared to be an influx of dissolved organic carbon followed by a decrease to pre-event concentrations which may have been associated with debris introduced to the lake as a result of the TSF dam failure.

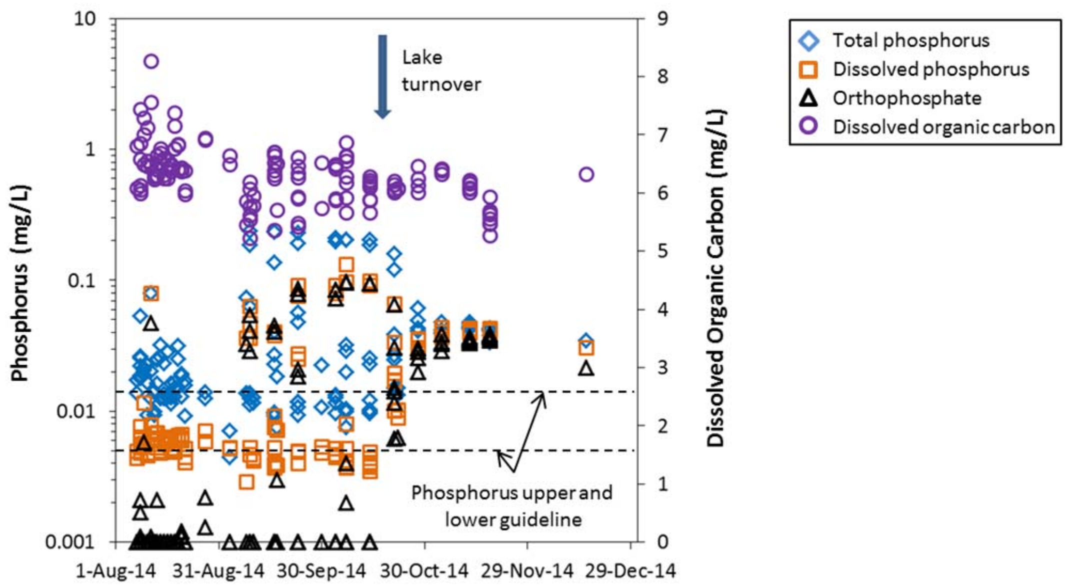

Figure 18: Temporal Variability in Phosphorus and Dissolved Organic Carbon in Polley Lake (18 stations)

5.2.2.2 Primary Productivity

There was no impairment of growth of either *Lemna minor* (vascular aquatic plan) or *Pseudokirchneriella subcapitata* (alga) in laboratory toxicity tests on water from Polley Lake (Minnow 2015b).

Measurement of Secchi depth commenced in early September once the lake was considered safe for boat access. The Secchi depths measured in Polley Lake post-event in September and October 2014 were similar to pre-event conditions in June and July 2014 and were within historical ranges (Figure 19). There was no indication of a reduction in light penetration into the lake surface based on Secchi depth measured post event, during the period of measurement.

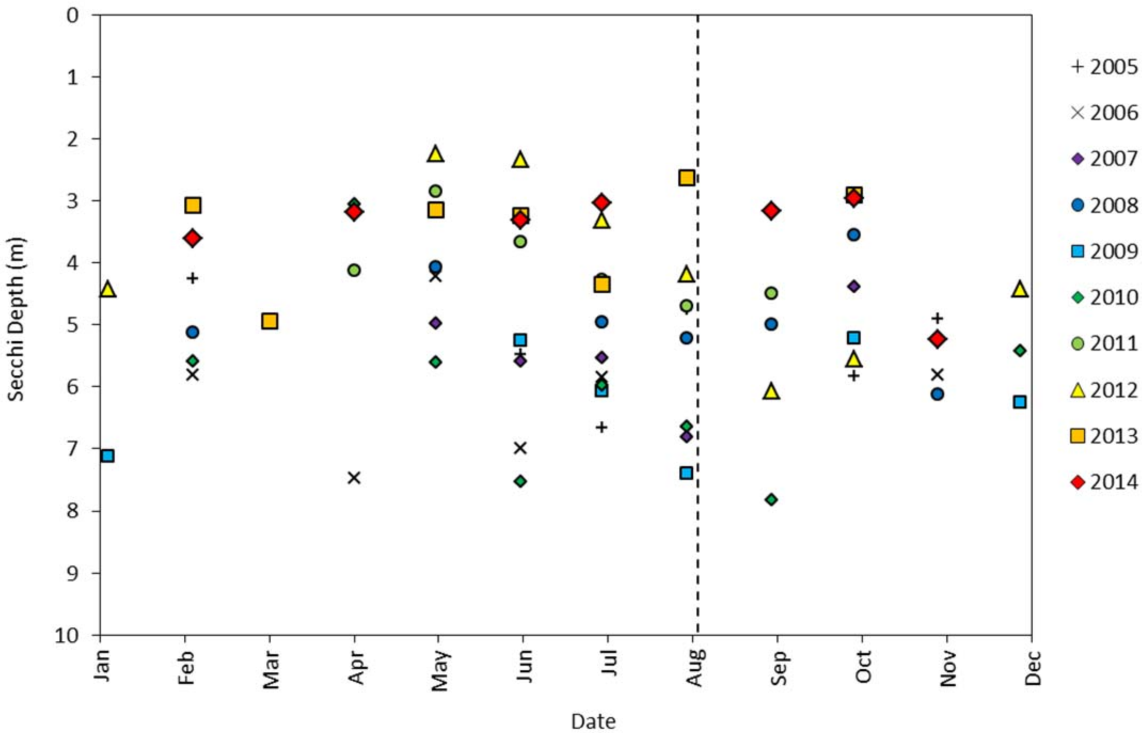

Figure 19: Secchi depth (monthly average) measured in Polley Lake from 2005 to 2014. Dashed line indicates date of TSF breach August 4, 2014.

The most recent pre-event data for chlorophyll *a* measured in Polley Lake is from baseline studies conducted in 1995 and 1996, in which mean chlorophyll *a* concentrations were reported to range from 0.4 to 1.0 µg/L (Minnow 2014). A change in nutrient concentrations and trophic status of the lake in 2010-2012 corresponded with observations of phytoplankton blooms. Post-event measurement of chlorophyll *a* was limited to three samples taken on September 9, 2014, with concentrations ranging from 5.2 to 6.6 µg/L. It is not known if the post-event chlorophyll *a* concentrations are different than immediately prior to the event.

5.2.2.3 Zooplankton Productivity

Water from Polley Lake was not acutely toxic to *Daphnia magna* or *Ceriodaphnia dubia* and did not affect reproduction in *Ceriodaphnia dubia* (Minnow 2015b).

As of the time of writing, zooplankton community data were not available to assess zooplankton productivity. However, recent sampling of zooplankton has been undertaken by MPMC. Condition factor of Rainbow Trout approximately seven weeks after the event was comparable to pre-impact condition factor, which suggests that the food supply for trout was within the range that might have been encountered previous to the event.

5.2.2.4 Benthic Invertebrates/Emerging Insects

Production of benthic invertebrates and emerging insects was disrupted in the littoral zone and immediately adjacent lakebed. Based on the findings of Minnow (2015a), this effect was temporary as invertebrates were found in most sediment samples collected in Polley Lake between August and October 2014.

5.2.3 Food Supply – Quality

No information is available regarding metal concentrations in the tissues of food items for Rainbow Trout. However, those data may be available in the future. Metal concentrations in Rainbow Trout collected shortly after the event were comparable to pre-event concentrations (SNC-Lavalin 2015a). Additional fish tissue collection is being planned.

5.2.4 Efficiency

The potential for effects on foraging efficiency and food capture is dependent on the species and habitat being occupied. Fish feeding in littoral and nearshore zones was likely not affected because turbidity was low (i.e., ≤ 3 NTU) in the top 7 m of the water column. Rainbow Trout length and weight data do not suggest that foraging efficiency was affected (Section 5.2.1).

5.2.5 Bioenergetics

Rainbow Trout condition factor data do not suggest that efficiency in conversion of energy was affected (Section 5.2.1).

5.3 Individual Performance

5.3.1 Stress

As discussed in Section 5.2.1, Fathead Minnow and Rainbow Trout exposed to Polley Lake water in laboratory toxicity testing and Rainbow Trout and Longnose Sucker collected from Polley Lake did not fail to grow, which is a potential outcome of stressors.

Fish tissue samples were collected for analytical chemistry for several sampling dates and locations. The data are provided in SNC-Lavalin (2015a) and will be assessed in the future ecological risk assessment.

5.3.2 Olfactory Effects

Olfactory effects were not assessed for Polley Lake because the rainbow trout in Polley Lake are a resident population. A migration barrier between Polley Lake and Quesnel Lake exists at Hazeltine Canyon.

5.3.3 Disease

TSS concentrations observed were not high enough to reduce the ability of fish to resist disease and thus an increase in the incidence of disease as a result of increased turbidity would not be expected (Figure 17). As discussed in Section 5.2.1, Fathead Minnow and Rainbow Trout exposed to Polley Lake water in laboratory toxicity testing and Rainbow Trout and Longnose Sucker collected from Polley Lake did not fail to grow, which is a potential outcome of disease.

5.4 Migration

Adult Rainbow Trout migrate into upper Hazeltine Creek from Polley Lake after ice-out in the spring (mid-April to mid-May) to spawn, returning to the lake by mid-June near the end of freshet and prior to the 2014 spawning period (SNC-Lavalin 2015b). The 2015 spawning migration to Hazeltine Creek was blocked by a fish fence because physical works associated with the rehabilitation of Hazeltine Creek were being undertaken.

5.5 Reproduction

5.5.1 Adult Maturation

Trout were observed gathering at the fish fence in spring 2015, suggesting normal maturation by trout in Polley Lake (Figure 20).

Figure 20: Photograph of Rainbow Trout Gathering at the Fish Fence at the Outlet from Polley Lake to Hazeltine Creek in Spring 2015.

5.5.2 Density-independent Reproductive Success (Spawning Habitat Quality)

Rainbow Trout were unable to access Hazeltine Creek in spring 2015 to spawn, which will likely reduce recruitment to the young-of-year age class in the lake.

5.5.3 Density-dependent Reproductive Success (Spawning Habitat Quantity

Rainbow Trout were unable to access Hazeltine Creek in spring 2015 to spawn, which will likely reduce recruitment to the young-of-year age class in the lake. Five drainages enter Polley Lake from the west side, and an evaluation of the suitability of these for rainbow trout spawning and rearing found that rearing habitat existed in two of these drainages (North and East Dump Creeks), although the habitat was characterized as poor (Sigma 2004, cited in Minnow 2014). Frypan Creek, the major inlet to Polley Lake, was observed to contain juvenile Rainbow Trout in September 2014 (Lirette 2015b); however it is unknown as to whether this represents usable spawning and rearing habitat relative to what had previously been accessible in Hazeltine Creek. A further consideration is the potential for interspecific competition between age 0 to 1+ Rainbow Trout which use the same food source as Redside Shiner, which Rainbow Trout avoid by rearing initially in Hazeltine (L. Williston, Ministry of Forests, Lands, and Natural Resource Operations [MFLNRO], pers. comm.). It is unknown at this time what effect loss of Hazeltine Creek as rearing habitat will have on the success of the 2015 year class.

5.6 Summary of Effects on Fish Productivity

The primary effect of the event on the Rainbow Trout of Polley Lake was the disruption to rearing habitat in Hazeltine Creek and the potential loss of a year-class of Rainbow Trout and the blockage of access to Hazeltine Creek for spawning in 2015 (Table 9). Post-event toxicity testing indicated that Polley Lake water did not affect survival or growth of fish, survival or growth of daphnid zooplankton, or growth of plant test species. Rainbow Trout and Longnose Sucker length and weight data suggest that feeding efficiency was not affected.

Table 9 Summary of Effects on Productivity of Fish in Polley Lake

Component of Productivity	Sub-component	Mechanism	Potential Effect on Productivity
Survival	Density independent mortality	Direct mortality	■ Possible, but not quantifiable as no dead fish were observed. Fish may also have been displaced.
		Exceedance of environmental tolerances	■ TSS concentrations could have been high enough in the south end of the lake during and immediately following the event to cause lethal conditions; however, the post-event water quality monitoring program did not identify concentrations above 50 mg/L. ■ Post-event toxicity testing indicated that Quesnel Lake water was not toxic to juvenile Rainbow Trout or Fathead Minnow
	Reduced habitat quality or quantity	Habitat supply limitation	■ There has been no quantitative estimate of the spatial extent of material covering habitat in the lake and the change in bathymetry cannot be reliably estimated because of a lack of reliable pre-event data
Growth	Fish growth	-	■ Growth of Fathead Minnow was not affected in laboratory water toxicity tests. ■ Rainbow Trout and Longnose Sucker collected post event were similar in size to those measured pre-event.
	Food supply	Quantity	■ There was no impairment in growth of an aquatic vascular plant or an algal test species. ■ Polley Lake water was not toxic to daphnid zooplankton and did not affect reproduction. ■ Production of emerging insects was disrupted on lakebed due to the alteration of the habitat. One month following the event, these areas were being recolonized. ■ In sediment toxicity tests, organic carbon was low in many samples and was associated with poor performance in growth or survival of test organisms.
		Quality	■ No information was available regarding potential change in food quality. However, metal concentrations in Rainbow Trout collected shortly after the event were comparable to pre-event concentrations
	Efficiency	Foraging	■ Rainbow Trout and Longnose Sucker length and weight data suggest that feeding efficiency was not affected.
Growth cont.	Efficiency cont.	Bioenergetics	■ Rainbow Trout and Longnose Sucker length and weight data suggest that conversion of energy was not affected.

Component of Productivity	Sub-component	Mechanism	Potential Effect on Productivity
Individual performance	Stress	Suboptimal environmental conditions	■ Rainbow Trout and Longnose Sucker length and weight data suggest that stress did not impair growth ■ Suspended sediments can cause change in behaviour; however, turbidity in the upper water column was lower than turbidity observed to cause such effects.
	Olfactory effects	Suboptimal environmental conditions	■ Copper concentrations were lower than those observed to cause effects.
	Disease	Infection	■ Rainbow Trout and Longnose Sucker length and weight data suggest that disease did not impair growth ■ TSS concentrations were lower than those reported in the literature to reduce the ability of a fish to resist disease.
Migration	-	Disruption of normal behaviour	■ Spawning migration of Rainbow Trout to Hazeltine was blocked for spring 2015.
Reproduction	Adult maturation	Suboptimal environmental conditions	■ Trout were observed gathering at the fish fence in spring 2015, suggesting normal spawning development.
	Density-independent reproductive success	Spawning habitat quality	■ Rainbow Trout were unable to access Hazeltine Creek in spring 2015 to spawn, which will likely reduce recruitment to the young-of-year age class in the lake
	Density-dependent reproductive success	Spawning habitat quantity	■ Rainbow Trout were unable to access Hazeltine Creek in spring 2015 to spawn, which will likely reduce recruitment to the young-of-year age class in the lake. Interspecific competition between age 0 to 1+ Rainbow Trout and Redside Shiner in Polley Lake; it is unknown what effect this may have on the success of the 2015 year-class.

Notes:
NA – not applicable; TSS – total suspended solids

6.0 QUESNEL RIVER IMPACT ASSESSMENT

The water quality parameters of potential concern identified for Quesnel River were turbidity and total copper (Golder 2015). Total copper was correlated with turbidity and thus inferred to not be bioavailable. This assessment therefore focussed on the potential effects associated with turbidity.

Several short-term pulses of turbidity were observed in Quesnel River in response to westward seiche events and a longer-term elevation in turbidity occurred during Quesnel Lake turnover (Figure 21). The turbidity was due to the suspension of fine particles and total suspended solids concentrations were at or below the detection limit of 3 mg/L.

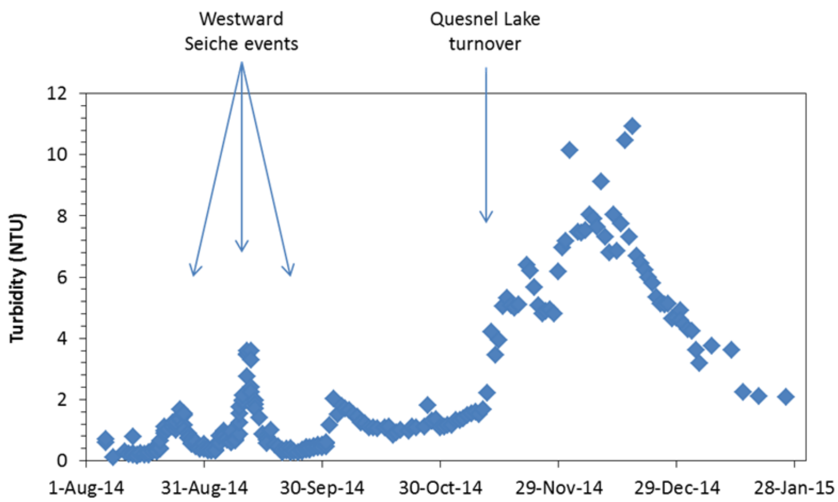

Figure 21: Temporal Variability in Turbidity in Quesnel River Near the Town of Likely

These suspended sediment levels were lower than those reported to result in changes to the following components of productivity.

6.1 Survival

Laboratory toxicity testing with Rainbow Trout (96-h LC50) and Fathead Minnow (7-day survival and growth) indicated that water from Quesnel River Lake was not lethal to these fish species (Minnow 2015b). Similarly, mortality did not occur during a an extended early life stage toxicity test using Quesnel River water when turbidity was highest.

6.2 Fish Growth

Growth of Fathead Minnow was not affected in the 7-day survival and growth tests conducted in water from Quesnel River (Minnow 2015b).

6.3 Food Supply

6.3.1 Primary Productivity

There was no impairment of growth of either *Lemna minor* (vascular aquatic plan) or *Pseudokirchneriella subcapitata* (alga) in laboratory toxicity tests on water from Quesnel River (Minnow 2015b).

Van Nieuwenhuyse (1983, cited in Birtwell 1999) calculated that an increase of 5 NTU would decrease the algal productivity of shallow clear-water streams by 3 – 13%. During the seiche events, turbidity was below this level of effect. During lake turnover, turbidity was greater than this effect level; however, primary productivity is naturally lower in fall and winter and a change in turbidity of 10 NTU would not be expected to further decrease productivity.

6.3.2 Benthic Invertebrates

Benthic drift has been observed to increase with the concentration of TSS and may occur within hours of a relatively small increase in TSS (10 mg/L). In comparison, changes in population sizes have been observed at higher TSS exposure (60 - 130 mg/L) over a period of > 50 days (Bilotta and Brazier 2008).

Minnow (2015a) collected benthic invertebrate samples from Quesnel River substrates at six locations in late October 2014, prior to Quesnel lake turnover and the increased turbidity observed through to January 2015. Benthic invertebrate abundance was higher at the three stations closest to the Quesnel Lake Outlet than the three stations further downstream and was greater than the reference stations. Richness and measures of diversity of the benthic community in the river near the Town of Likely were similar to the reference locations as were the relative abundance of larval Ephemeroptera (mayflies), Plecoptera (stoneflies) and Trichoptera (caddisflies), which are often collectively referred to as EPT taxa and used as an indicator of potential exposure to contaminants as they tend to be sensitive to metals. These results suggest that the benthic invertebrate community was not significantly affected by the transient pulses of turbidity at least up to the time of lake turnover.

Minnow (2015a) also collected benthic invertebrate samples from Quesnel River for analytical chemistry. Copper was higher in whole community samples collected near the Town of Likely than in benthos from the reference area (Cariboo River); however, Minnow (2015a) did not find a correlation between tissue and water chemistry that would explain the difference. As discussed in Section 4.2.3, the observed concentrations were lower than lower than dietary no-effect levels for Rainbow Trout (e.g., Miller et al. 1993).

Additional sampling of the benthic invertebrate community in the fall of 2015 will help confirm whether or not effects to the benthic invertebrate community occurred during lake turnover.

6.4 Individual Performance of Fish

Fish behaviour such as avoidance, breakdown of normal dominance hierarchies, lack of territorial defence, and increased gill flaring has been observed at turbidity levels on the order of >50 NTU (Berg and Northcote 1985; Bisson and Bilby 1982). As discussed above, Fathead Minnow and Rainbow Trout exposed to Quesnel River water in laboratory toxicity testing did not fail to grow, which is a potential outcome of the stressors identified above.

Samples of several fish species were collected for analytical chemistry from Quesnel River; the data are provided in SNC-Lavalin (2015a) and will be assessed in the future ecological risk assessment.

6.5 Reproduction

Chapman (1988) reviewed a large number of papers investigating the effect of fine sediments on alevin emergence and survival in salmonid species. While differences between fish species and site conditions caused large variations in the actual relationship between percent fines and alevin (newly-hatched fish) emergence, a general trend of decreased alevin emergence correlated with increased percentages of fine-grained sediment in gravel. The major factor contributing to egg and alevin survival was the inter-gravel dissolved oxygen concentration; fine-grained sediment clogged the interstitial spaces, and therefore reduced the flow of oxygen-rich water to the redd.

An early life stage test with rainbow trout was carried out by MPMC using water samples regularly collected from the Quesnel River (QUR-1) between November 25 and December 22, 2014. The water samples were collected to coincide with egg availability which happened to also coincide with the period of greatest turbidity in Quesnel River. There were no reported adverse effects on the survival or normal development of Rainbow Trout eggs exposed to the water through to hatching of the alevin stage (MPMC 2015). Similar results were observed when the test was repeated with water samples collected from December 10, 2014 to January 7, 2015 (MPMC, unpublished data). These results suggest that the increase in turbidity in the Quesnel River after turnover of Quesnel Lake was unlikely to have an effect on incubating salmonid eggs in the river.

7.0 SUMMARY

This report provides a preliminary assessment of potential effects on the aquatic health of Quesnel and Polley Lakes, and Quesnel River, following the TSF dam failure at Mount Polley Mine. The assessment was structured based on DFO guidance on evaluating productivity to facilitate the ongoing efforts of the Habitat Remediation Working Group that has been established. Changes in productivity were assessed by comparing pre- and post-event data were available, and by evaluating data in the context of the literature with consideration of site-specific conditions.

To facilitate the assessment of potential effects on productivity a conceptual ecological model was developed for fish-habitat-food interactions. These habitat and food requirements were grouped, resulting in three general assemblages applicable to a summer condition when the event occurred. The three assemblages assist in identifying how potential stressors related to the event may affect lake productivity. The three fish-habitat-food assemblages and the preliminary potential for effects identified were as follows.

Littoral Zone and Benthic Habitats - Fish associated with the littoral zone and benthic habitats are oriented to the near-shore environment and feed largely on benthic prey (e.g., amphipods, larvae and pupae of aquatic insects such as chironomids), periphyton, or in some cases crustacean zooplankton in the water column. Fish in this group include early juvenile stages of salmon, Burbot, and Lake Whitefish and are benthivores (i.e., their food comes from benthic substrates), and forage fish such as sucker, sculpin, chub, shiner and Northern Pikeminnow. The event resulted in the alteration of littoral habitat at the mouth of Hazeltine Creek, resulting in the displacement or potential (unconfirmed) loss of fish in the area. Debris was also deposited on the lakebed in the profundal area, which resulted in a change in the benthic habitat and a potential disruption in the benthic invertebrate community. The impact on the bed of Quesnel Lake continues to be studied. Although early sampling suggests that some recovery may have begun, benthos sampling subsequent to deposition and settling of the sediments is necessary to confirm if the impact is of a transient nature. Post-event toxicity testing indicated that Quesnel Lake water did not affect survival or growth of fish or growth of plant test species and geochemical evaluations carried out have found that the tailings will be chemically stable in the lakes and are not expected to leach metals.

Open-Water Habitat and Fish that Feed on Emerging Insects - Fish associated with open-water habitat and feed on emerging insects (e.g., chironomids) include Mountain Whitefish and smaller Rainbow Trout. Larger Rainbow Trout in Quesnel Lake may consume juvenile Sockeye Salmon and Kokanee. This assemblage also applies to Polley Lake, in which the main fish species is Rainbow Trout. Production of emerging insects was disrupted on the bed of both Quesnel and Polley Lakes. Although early sampling suggests that some recovery may have begun, benthos sampling subsequent to deposition and settling of the sediments is necessary to confirm if the impact is of a transient nature. Post-event toxicity testing indicated that lake water did not affect survival or growth of fish or growth of plant test species. In Polley Lake, Rainbow Trout size did not appear to change; however, the event likely affected reproduction through the loss of eggs in the Upper Hazeltine Creek spawning habitat in 2014 and potentially through the loss of use of that habitat in 2015.

Open-Water Habitat and that Fish that Feed on Crustacean Zooplankton - The assemblage of fish associated with open-water habitat and which feed on crustacean zooplankton consists of juvenile Sockeye Salmon and Kokanee. During the summer, this assemblage may also include Lake Trout. Post-event toxicity testing indicated that Quesnel Lake water did not affect survival or growth of fish, survival or growth of daphnid zooplankton, or growth of plant test species. The literature indicates that the direction of change in primary productivity as a result of introduction of suspended sediments to a lake depends on whether the phytoplankton are light limited or nutrient limited. The preliminary information available at this time suggest that there was an influx of phosphorus into Quesnel Lake and although changes in phytoplankton and zooplankton biomass were not observed, juvenile Sockeye Salmon collected west of Cariboo Island were larger than those from the lake east of Cariboo Island.

Quesnel River experienced several pulses of turbidity water during transient seiche (internal lake wave) events and lake turnover. Post-event toxicity testing indicated that Quesnel River water did not affect survival or growth of fish, development of Rainbow Trout eggs through to alevins, survival or growth of daphnid zooplankton, or growth of plant test species. Richness and measures of diversity of the benthic invertebrate community in the river near the Town of Likely were similar to the reference locations as were the relative abundance of species sensitive to metals.

Some effects are duration dependent and additional data collection is presently underway that will further inform the understanding of the effect the event had on Quesnel and Polley Lakes and Quesnel River:

- MPMC commenced water quality and zooplankton sampling in May, 2015.
- The benthic invertebrate community in Quesnel and Polley Lakes will be sampled again in summer 2015 to evaluate the continuing improvement in abundance and diversity of benthos in the disturbed areas of the lakebed.
- The disturbed area of the lakebeds will be monitored for habitat quality in summer 2015.

Finally, a human health and ecological risk assessment will be undertaken to evaluate the potential effects of the chemical parameters of concern on productivity of the lake environments. This will include an interpretation of fish tissue chemistry collected following the event.

8.0 CLOSURE

We trust that this report provides sufficient information for your present needs. If you have any questions, please do not hesitate to contact the undersigned at 604-296-4200.

10.0 GLOSSARY

Benthic	At the lake bed.
Benthivore	An animal that eats benthic prey
Bioaccumulation	The accumulation of a substance in the tissues of an aquatic organism through exposure to water and diet.
Bioavailability	The portion of a substance or chemical that is immediately available for uptake by organisms. Bioavailability of different substances can change over time.
Biomass	The mass of biological material, including plants, animals and decaying organic matter, present within a particular habitat, area or ecosystem at any one time
Chlorophyll *a*	A photosynthetic pigment found in plants responsible for the conversion of inorganic carbon and water into organic carbon. The concentration of chlorophyll *a* is an indicator of algal concentration.
Dimictic	Refers to lakes that mix from top to bottom twice a year; mixing occurs in spring and fall.
Dissolved organic carbon	The dissolved portion of organic carbon in water. It is comprised of humic substances and partly degraded plant and animal materials.
Dissolved oxygen	The amount of free oxygen dissolved in water, usually expressed in milligrams per litre (mg/L), parts per million (ppm), or percent of saturation (%). Adequate concentrations of dissolved oxygen are necessary for fish and other aquatic organisms.
Emerging insect	Insects that have a water-based larval stage and a flying adult stage.
Epilimnion/epilimnetic	The water column above the thermocline.
Epiphyton	Algae that grow on the surfaces of aquatic plants.
Euphotic zone	The depth at which light diminishes to 1%.
Forage fish	Small fish that are prey for larger fish
Hypolimnion	The water column below the thermocline.
Limnetic zone	The water column in the euphotic zone.
Littoral zone	The area of the lakeshore where aquatic plants grow.
Oligotrophic	Trophic state classification for lakes characterized by low productivity and low nutrient inputs (particularly total phosphorus).
Periphyton	Algae that grow on the surface of rocks.
Phytoplankton	Free-floating plants/algae and photosynthetic bacteria.
Piscivore	An animal that eats fish.
Planktivore	An animal that eats plankton.
Profundal zone	The water column below the euphotic zone.
Seiche	A type of long-wavelength wave that occurs as a result of some disturbance within waterbody that is relatively closed-off from the outside environment. Long waves resonate outward to the boundaries of the waterbody, and then resonate back inward.
Stratification	The process by which the water column develops layers of water separated by a density barrier.
Thermocline	The location of a sharp change in temperature of the water column that causes a density barrier and limits mixing of the water column.
Zooplankton	Free-floating invertebrates.

As a global, employee-owned organisation with over 50 years of experience, Golder Associates is driven by our purpose to engineer earth's development while preserving earth's integrity. We deliver solutions that help our clients achieve their sustainable development goals by providing a wide range of independent consulting, design and construction services in our specialist areas of earth, environment and energy.

June 3, 2015

FINAL REPORT / V-01
621717 - 626349

EXECUTIVE SUMMARY

The Fish and Fish Habitat Impact Assessment (FFHIA) describes historical or pre-event baseline fisheries resource information for water courses and water bodies affected by the TSF dam foundation failure (henceforth referred to as the TSF dam failure), and it assesses the potential effects to those resources, including describing the potential impacts to fish and fish habitat.

Specifically, the FFHIA qualitatively and where possible quantitatively, identifies the potential impact to fish species including their productivity and habitats. The focus of this assessment was on alterations to the physical properties of fish habitat, and on fish species that are part of commercial, recreational or aboriginal fisheries.

Note that in this assessment physical habitat properties include the geomorphological characteristics and biological attributes that determine habitat structure. Physical habitat does not include physiochemical attributes of stream or lake water (e.g., water chemistry, water temperature, water clarity, water quantity or light intensity). Alterations to physiochemical properties will be addressed in the Mount Polley Tailings Dam Failure – Surface Water Quality Impact Assessment (Golder Associates Ltd. 2015a) and Mount Polley Tailings Dam Failure – Quesnel and Polley Lakes Aquatic Productivity Impact Assessment. (Golder Associates Ltd. 2015b.).

The area included in the FFHIA encompasses specific fish-bearing water courses and water bodies directly and potentially affected by the TSF dam failure. This includes the Hazeltine Creek watershed consisting of Polley Lake and Hazeltine and Edney creeks. Specific areas included the entire Hazeltine Creek mainstem between Polley Lake and Quesnel Lake, as well as lower Edney Creek (i.e., lower reach near the confluence with Hazeltine Creek) and surrounding riparian habitats. The assessment area also includes the shoreline and littoral region where Hazeltine Creek enters Quesnel Lake, the West Arm of Quesnel Lake, and upper Quesnel River from the confluence of Quesnel Lake to just downstream of the UNBC Quesnel River Research Center.

The following summarizes the main findings of the FFHIA for the identified water courses and water bodies.

Hazeltine Creek

Approximately 62,616 m^2 of aquatic habitat and 717,249 m^2 of riparian habitat was estimated to have been permanently altered on Hazeltine Creek.

There is the potential for subsequent Rainbow Trout reproductive events to be inhibited, which could affect ongoing population viability and productivity. Spawning Rainbow Trout returning to upper Hazeltine Creek from Polley Lake to reproduce may seek out other nearby watercourses to undertake their reproductive cycle, but it is unknown whether sufficient quantities and quality of spawning habitat exists in the surrounding area to accommodate them. Rainbow Trout are the most abundant and widely distributed fish species in lower Hazeltine Creek relative to other fish species present in the creek. Re-establishing access to habitat in lower Hazeltine Creek will offer opportunity for spring spawning Rainbow Trout to successfully migrate and reproduce to initiate the natural recruitment process. Other fish species also utilize lower Hazeltine Creek, but in lower numbers, suggesting preferred habitat conditions in lower Hazeltine Creek quite possibly were not present.

Overall, it was generally not possible to directly account for losses of fish or production in upper and lower Hazeltine Creek due to the TSF dam failure because of a lack of baseline species population parameters and production estimates. Although static data (i.e., Catch Per Unit Effort, densities/biomass) was somewhat available, it could not be effectively applied to produce production rates estimates. It is recommended that an effectiveness and biotic response monitoring program be implemented to monitor population dynamic productivity parameters once Hazeltine Creek has been rehabilitated.

Edney Creek

Approximately 2,390 m^2 of aquatic habitat and 20,215 m^2 of riparian habitat was altered in lower Edney Creek.

The amount of habitat in Edney Creek altered by the TSF dam failure was small in comparison to habitat available in the Edney watershed, thus the current obstruction to upstream migration, caused by material from the TSF, and potential loss of reproductive events of Rainbow Trout appear to present the primary concern to Rainbow Trout population productivity. Although there is limited evidence of other fish species utilizing Edney Creek, restoring access may also contribute to the productivity of other species (i.e., Coho Salmon) utilizing or migrating out from Edney Creek. It is our understanding from Mount Polley Mining Corporation that rehabilitation of Edney Creek and its connectivity to Quesnel Lake was commissioned prior to spring 2015 with the aim to allow for upstream and downstream access (migration) for fish.

Quesnel River

No permanent physical alteration of habitat is believed to have occurred in the Quesnel River. The potential for water quality-related effects are addressed in the Golder (2015a), Mount Polley Tailings Dam Failure – Surface Water Quality Impact Assessment. The potential for settling of suspended particles is being addressed by Minnow Environmental Inc. (Minnow Environmental) through the use of sediment traps (Minnow Environmental 2015).

Quesnel Lake

It was estimated that the TSF dam failure permanently altered a 2,081 m length of West Basin shoreline at the mouth of Hazeltine Creek (about 6% of the total shoreline in the West Basin), and about 94,394 m^2 or 6.5% of the total West Arm littoral zone (0-6 m depth). Further, about 15% of ‘very high’ rated juvenile fish habitat at the mouth of Hazeltine Creek was altered. Finally, Tetra Tech (2015) determined that about 1.81 km^2 of the surface area of the lake-bed below the 100-m depth contour was permanently altered by the event.

Overall, it was generally not possible to directly account for losses of fish or production in the West Arm of Quesnel Lake due to the TSF dam failure because of a lack of baseline information about species population properties such as production estimates, densities/biomass or location and surface area of key habitats.

Polley Lake

Tailings from the TSF dam failure entered Polley Lake at the lake outlet to Hazeltine Creek; however, there are no current estimates of how much linear shoreline or surface area of lake bed was altered by the event.

The TSF dam failure resulted in blockage of upper Hazeltine Creek and hence the Polley Lake Rainbow Trout population lost access to creek spawning habitat for one season. A reduction in rainbow trout returning to Polley Lake may affect future angling results.

The TSF dam failure may have impacted habitats important to Redside Shiner and Longonse Sucker in Polley Lake. However, there is currently insufficient scientific evidence confirming the habitats or population properties of these species in Polley Lake.

Recommendations

The duration and severity of the impacts (i.e., permanent and/or temporary alterations) as a result of the TSF dam failure to fish production and habitat will ultimately depend on the nature and success of the rehabilitation (i.e., offsetting) efforts to altered riverine and lacustrine habitats as well as monitoring the affected creek and lake systems for potential long-term (chronic) effects. The characterisation of effects should be reassessed once rehabilitation efforts are complete, and should continue to be re-examined in the context of the results of any effectiveness and biotic-response monitoring. In addition, an ecological risk assessment should be completed to prioritize and focus the monitoring and rehabilitation programs.

1 BACKGROUND

On August 4, 2014, a foundation failure of the Tailings Storage Facility (TSF) dam occurred at Mount Polley Mine. The purpose of this Fish and Fish Habitat Impact Assessment (FFHIA) is to describe historical or pre-event baseline fisheries resource information for watercourses and water bodies affected by the TSF dam foundation failure (henceforth referred to as the TSF dam failure), and to assess potential effects on those resources, including understanding the potential impacts to fish and fish habitat.

1.1 Fish Habitat and Productivity

Under the Canadian federal *Fisheries Act* “fish habitat” means spawning grounds and any other areas, including nursery, rearing, food supply and migration areas, on which fish depend directly or indirectly in order to carry out their life processes. Further, Fisheries and Oceans (DFO) defines a permanent alteration to fish habitat as a modification of a special scale and a duration that limits or diminishes the ability of fish to use such habitats as spawning grounds, or as nursery, rearing, or food supply areas, or as a migration corridor, or any other area in order to carry out one or more of their life processes.

Habitat necessarily includes all of the physical, chemical, and biological attributes that affect or sustain fish but the focus in this FFHIA is on alteration (permanent or temporary) of physical habitat properties of water courses and bodies that may affect fish, including species that are part of commercial, recreational or aboriginal fisheries. Physical habitat properties include the geomorphological characteristics and biological attributes that determine habitat structure. The six main attributes that are the principal determinants of the physical habitat structure provided by a watercourse include: stream size and channel dimensions, channel gradient, channel substrate, size and type, habitat complexity and cover, vegetation cover and structure of the riparian zone, and channel-riparian interactions (Kaufmann et al. 1999). In lakes, physical habitat structure refers to shoreline riparian vegetation, aquatic macrophytes, littoral fish cover, littoral bottom substrate, lake shoreline substrate, littoral depth, lake morphometry, bathymetry, and lakebed substrate (Kaufmann et al. 2014).

In the FFHIA, physical habitat does not include physiochemical attributes of stream or lake water (e.g., water chemistry, water temperature, water clarity, water quantity or light intensity). Alterations to physiochemical (i.e., water quality) properties will be addressed in the Mount Polley Tailings Dam Failure – Surface Water Quality Impact Assessment (Golder Associates Ltd. 2015a) and Mount Polley Tailings Dam Failure – Quesnel and Polley Lakes Aquatic Productivity Impact Assessment. (Golder Associates Ltd. 2015b.) Results from fish tissue sampling are addressed in the separate technical memorandum prepared by SNC-Lavalin, titled ‘*Fish Tissue Results for Samples Collected Following the Mount Polley Tailings Storage Facility Dam Failure*’.

Most relevant to the FFHIA is the potential for lost fish productivity as a result of impacts to habitat. Fisheries productivity can be defined as the sustained yield of all component populations and species and their habitats, which support and contribute to a fishery in a specified area. It is determined by the vital rates of reproduction, growth, and survival, and life history characteristics of the population (e.g., age at maturity).

Fish production has a spatial and temporal context, and the production of a fish population depends on the amount and quality of habitat required for each life stage. Any adverse change in a component of productivity is expected to have some negative effect on fish. For example, activities that cause a decrease in habitat quantity cause a decrease in supply of habitat and will potentially result in density-dependent limitation caused by a reduction in carrying capacity (Bradford et al. 2014).

The life cycle of a typical fish can be used as a template for considering the assessment of effects on habitat and fish productivity. Activities that restrict an individual fish from completing their life cycle or that diminish their vital rates (reproduction, growth, survival) will ultimately result in a reduction in yield at the population level (Bradford et al. 2014); such activities will interfere with the sustainability of fish productivity. Table 1-1 briefly summarizes some of the key components and mechanisms typically considered in assessments of fish productivity, and the location of the assessment within the impact assessment documents.

Table 1-1: Summary of Fish Productivity Components and Mechanisms

Productivity Component	Mechanism	Impact Assessment Document
Growth	Reduction of food quality Reduction in food quantity	Considered in the Golder Associates Ltd. (2015a) Mount Polley Tailings Dam Failure – Surface Water Quality Impact Assessment and Golder Associates Ltd. (2015b) Mount Polley Tailings Dam Failure – Quesnel and Polley Lakes Aquatic Productivity Impact Assessment.
Individual Performance	Increase in infection, disease, bioaccumulation	Considered in the Golder Associates Ltd. (2015a) Mount Polley Tailings Dam Failure – Surface Water Quality Impact Assessment and Golder Associates Ltd. (2015b) Mount Polley Tailings Dam Failure – Quesnel and Polley Lakes Aquatic Productivity Impact Assessment.
Survival	Direct mortality	Considered in this FFHIA
	Loss or alteration of rearing & overwintering habitat (quantity and quality)	Considered in this FFHIA

Productivity Component	Mechanism	Impact Assessment Document
	Exceedance of environmental tolerances (e.g., turbidity, contamination)	Considered in the Golder Associates Ltd. (2015a) Mount Polley Tailings Dam Failure – Surface Water Quality Impact Assessment and Golder Associates Ltd. (2015b) Mount Polley Tailings Dam Failure – Quesnel and Polley Lakes Aquatic Productivity Impact Assessment.
Migration	Blocking of passage	Considered in this FFHIA
	Deterioration of migrations conditions	Considered in this FFHIA
	Loss of shallow water corridors	Considered in this FFHIA
Reproduction	Sub-optimal environmental conditions	Considered in the Golder Associates Ltd. (2015a) Mount Polley Tailings Dam Failure – Surface Water Quality Impact Assessment and Golder Associates Ltd. (2015b) Mount Polley Tailings Dam Failure – Quesnel and Polley Lakes Aquatic Productivity Impact Assessment.
	Loss or alteration of spawning habitat (quantity and quality)	Considered in this FFHIA
	Loss of access to spawning habitat	Considered in this FFHIA

Koops et al. (2013); Bradford et al. (2014)

Link to Comprehensive Environmental Impact Assessment Workplan (CEIA)

A number of aquatic components described in the Aquatic Impact Assessment section of the CEIA workplan (dated August 29, 2014), such as primary productivity, are addressed in the technical reports summarized in Table 1-1.

1.2 Objective

The objective of the FFHIA was to qualitatively and/or quantitatively identify the potential impact to fish species including their productivity and habitats. The focus of this assessment was on alterations to the physical properties of fish habitat, and on fish species that are part of commercial, recreational or aboriginal fisheries.

1.3 Acknowledgements

Cameron Wallace, B.Sc. (GIS Analyst) managed the preparation all key maps. Natalie Neufeld assisted in data management and in preparation of data summary tables.

Raw fisheries data for Hazeltine and Edney creeks as well as Polley and Quesnel lakes was provided by both Mount Polley Mining Corporation (MPMC) and Minnow Environmental Inc. (Minnow Environmental) personnel. The Project Sponsor was Gordon Johnson, M.Sc., P.Eng.

2 IMPACT ASSESSMENT AREA

The areas included as part of the FFHIA encompass specific fish-bearing watercourses and waterbodies directly and potentially affected by the TSF dam failure. This includes the Hazeltine Creek watershed consisting of Polley Lake and Hazeltine and Edney creeks. Specific areas included the entire Hazeltine Creek mainstem between Polley Lake and Quesnel Lake, as well as lower Edney Creek (i.e., lower reach near the confluence with Hazeltine Creek) and surrounding riparian habitats. The assessment area also includes the shoreline and littoral region of where Hazeltine Creek enters Quesnel Lake, the West Arm of Quesnel Lake, and upper Quesnel River from the confluence of Quesnel Lake to just downstream of the UNBC Quesnel River Research Center.

Bootjack Creek (a tributary to upper Hazeltine Creek) has not been included in the scope of this assessment. Bootjack Creek was historically impacted by mine development in 1913. It is our understanding from MPMC that emergency measures commenced post TSF dam failure to salvage/remove fish from the watercourse as fish had been cut off from accessing Polley Lake via Hazeltine Creek. Prior to the TSF dam failure a plan was being considered to decommission the creek due to encroaching mine disturbance on the remaining Bootjack Creek catchment. In October 2013, discussions commenced between MPMC, DFO, the Ministry of Forests, Lands and Natural Resource Operations, First Nations representatives, and various local stakeholders with respect to potential offsetting options to address the permanent removal of Bootjack Creek. Given the current situation, it is our understanding from MPMC that offsetting for impacts to Bootjack Creek incurred prior to and post TSF dam failure will be captured in the offsetting measures developed and agreed to as part of the TSF dam failure.

Figure 2-1 (Appendix I) illustrates the defined fisheries assessment areas noted above.

3 METHODOLOGY

A general approach was used to conduct the FFHIA, which included the following two steps:

i. Review and compilation of available historical information to generate pre-TSF dam failure baseline data (Section 3.1); and

ii. Assessment of potential physical effects resulting from the TSF dam failure and potential implications to fisheries productivity (Section 3.2); and

The following sections discuss each step in further detail.

3.1 Compilation of Fisheries Baseline Pre-TSF Dam Failure

Baseline information was compiled from numerous historical and more recently generated data sources (DWB 2014; Lirette 2015; MPMC 2009; Cariboo 2008a, 2009; and Minnow Environmental 2009, 2011, 2012, 2014) such as field data collected following the TSF dam failure (i.e., water quality, fish tissue residue, benthic invertebrate etc.), where appropriate and applicable.

Representatives of the following agencies and groups were contacted to inquire whether they had any pre-event data or if they could recommend other data sources for Hazeltine and Edney creeks, Quesnel River, and Polley and Quesnel lakes:

- BC Ministry of Environment (BC MoE);
- DFO;
- Local consultants who have worked in the Likely and Quesnel Lake area; and
- Regional researchers at the University of British Columbia (UBC) and University of Northern British Columbia (UNBC).

Additionally, a number of historical studies and publically available websites were reviewed and accessed to generate the pre-event fisheries baseline conditions for Hazeltine and Edney creeks, Quesnel River, and Polley and Quesnel lakes. All data sources have been listed in the Reference Section (Section 7).

3.2 Assessment of Potential Physical Effects Resulting from the TSF Dam Failure

For the purpose of the FFHIA, aquatic habitat is defined as the permanently or temporarily wetted riverine or lacustrine habitat that supports one or more life history phases (rearing, overwintering, spawning, etc.) of an aquatic organism (Lewis et al. 2013). Riparian habitat is defined as the area of the streambank, including any side channels and associated banks, which contain upland areas not normally inundated during high water conditions (Chilibeck et al. 1992).

Direct and indirect effects were evaluated and quantified (where applicable) for both (1) aquatic and riparian habitat, and, where feasible, (2) fish 'productivity' for those watercourses with adequate fish-specific data. Direct effects are referred to as "footprint" effects because they typically alter or disturb habitat within the footprint of a 'project'. In the case of the TSF dam failure, the "footprint" effects are comprised of those habitats altered in Hazeltine and Edney creeks and the shorelines and lakebeds (where applicable) of Polley and Quesnel lakes. Indirect effects are generally secondary effects from footprint effects, such as deposition of sediment. Note that this FFHIA does not address indirect (secondary) effects with respect to water quality or sediment deposition as they will be covered in the Water Quality Impact Assessment and the Quesnel and Polley Lakes Aquatic Productivity Impact Assessment (Golder 2015a,b).

The methods applied to evaluate alterations to applicable watercourses and waterbodies affected by the TSF dam failure are described below.

3.2.1 Hazeltine Creek and Edney Creek

Quantification of Aquatic Habitat Footprints

The extent of aquatic footprints in Hazeltine and Edney creeks were calculated based on the following protocol:

- Satellite images of the watercourses, after the TSF dam failure, were overlayed on top of images prior to the release to visually establish the extent of effects to aquatic and riparian areas in affected watercourses. For Hazeltine Creek this included the length between the outlet at Polley Lake and the inlet at Quesnel Lake. For Edney Creek, the upstream extent of tailings were determined with UTM coordinates;
- The aquatic area of affected watercourses was calculated using the average channel (bankfull) width of the watercourse multiplied by the length that was affected. Different calculations were performed for each of the two watercourses (Hazeltine and Edney creeks);
- Hazeltine Creek – the average channel (bankfull) width multiplied by the length of each of nine reaches assessed in 2006 (Minnow Environmental 2007). As no channel width data was available for the section of the watercourse upstream of the nine reaches, the average channel width of the nine reaches was used as an estimate for this remaining section; and
- Edney Creek – the average channel (bankfull) width multiplied by the length of affected channel. The channel width was obtained from a site assessment conducted in 1997 (Hallam Knight Piésold 1997).

Aquatic habitat affected by the TSF dam failure was also compared to the total fish-bearing aquatic area of the watershed (i.e., for Edney Creek) and reported as a percentage of the watershed affected by the TSF dam failure.

Quantification of Riparian Habitat Footprints

Alteration of riparian habitat was calculated based on the application of the Riparian Management Area (RMA) of each watercourse, obtained from the BC Ministry of Forests' *Riparian Management Area Guidebook* (BC MoF 1995), and measuring the distance from the watercourse top of bank and away from the channel at a perpendicular angle for a set distance. Given that the exact top of bank was not known, the distance was measured from the edge of the channel. These RMAs include a reserve zone and a management zone and are ultimately based on the stream riparian class and average channel width (Table 3-1). The stream riparian class is based on fish presence in the watercourse; S1 to S4 classes are fish-bearing whereas S5 and S6 classes are non-fish-bearing. A number of calculations were performed for each of the two watercourses (Hazeltine and Edney creeks):

- Hazeltine Creek – as all of the riparian vegetation on both banks (riverbank left and right) were affected by the TSF dam failure, the areal extent was estimated by multiplying the RMA on both sides of the watercourse by the channel length in each reach using Geographic Information System (GIS) software. In some sections of the creek, the RMA did not extend past the affected area of the creek. Sections of Hazeltine Creek riparian areas that overlapped other watercourse riparian areas (i.e., Edney Creek) were not included so as not to double-count total effect estimates.
- Edney Creek – although there were sections of riparian vegetation that appeared to be still intact, we applied a conservative approach and assumed that all riparian vegetation within the zone of influence was affected. Thus, the areal extent of the riparian footprint was estimated by multiplying the RMA on both sides of the watercourse by channel length using a GIS.

Table 3-1: Specified Minimum RMA Slope Distances for Stream Riparian Classes

Riparian Class	Average Channel Width (m)	Reserve Zone Width (m)	Management Zone Width (m)	Total RMA Width (m)
S1 large rivers	≥100	0	100	100
S1 (except large rivers)	>20	50	20	70
S2	>5≤20	30	20	50
S3	1.5≤5	20	20	40

S5	>3	0	30	30
S6	≤3	0	20	20

Gray cells - Fish stream or community watershed. White cells - Not fish stream and not in community watershed.
(BC MoF 1995)

A fish habitat survey conducted in 2006 found no surface water tributaries to Hazeltine Creek with the exception of Edney Creek (Minnow Environmental 2007). As such, Hazeltine and Edney creeks were the only watercourses considered in the impact assessment.

3.2.2 Hazeltine Creek and Edney Creek: Effects to Fish Productivity

The estimated loss of fish productivity to Hazeltine and Edney creeks was evaluated using three approaches: 1) the quantification and value (quality) of altered aquatic and riparian habitats; 2) fish abundance information (i.e., catch per unit effort [CPUE]) was highlighted for those species with readily available data; and 3) a crude estimate of life stages potentially displaced as a result of the TSF dam failure were compiled and described. All three measures have been identified as surrogates of productivity (Bradford et al. 2013).

3.2.3 Quesnel Lake and Polley Lake: Effects to Fish Productivity

The lake impact assessment considers the interactions between three main components: 1) physical properties of each lake zone; 2) fish groups; and 3) fish productivity properties. Each component is briefly discussed below.

3.2.3.1 Lake Zones

To facilitate an understanding of the potential effects of the TSF dam failure on fish habitat and productivity of the lakes, four major zones were identified based on standard limnological categorizations (e.g., Wetzel 2001). These included:

Littoral Zone: A zone from the natural shoreline moving lake-ward including the maximum depth of aquatic plants.

Limnetic Zone: The open water area adjacent to the littoral zone where the main photosynthetic activity from phytoplankton takes place. The depth of the limnetic zone extends through the thermocline to the limit of one-percent light penetration (i.e., euphotic zone).

Profundal Zone: Deep open water area of no light penetration beneath the limnetic zone extending to just above the lake-bed.

Benthic Zone: Includes the lakebed sediment surface and sub-surface layers extending from the littoral zone.

3.2.3.2 Fish Groups

To facilitate the assessment of the TSF dam failure on the productivity of fish in the four zones of the lakes, the fish species thought to occur in each lake were separated into four major groups based on similar life histories and ecological function. This approach was necessary because little information is available describing the current presence/absence, distribution or abundance of each individual fish species in the two lakes.

3.2.3.3 Fish Production

The life cycle of a typical fish can be used as a template for considering the assessment of effects on fisheries productivity. Productivity results from individuals completing their life cycle and meeting five critical production components related to: growth, individual performance, survival, migration, and reproduction that will generate sufficient yield at the population level (Table 1-1).

3.2.3.4 Links between TSF Dam Failure and Fish

The potential effects of the TSF dam failure on physical habitat and productivity of fish in the lakes were considered by evaluating each of the four major lake zones.

Quesnel Lake

To determine the linear extent and surface area of littoral zone habitat altered, the region satisfying depth range requirements for the shallow-water aquatic plant *Potamogeton* sp. (0-6 m) was quantified for the pre-event shoreline.

A coarse[1] pre-event bathymetric survey (Coast Pilot 2001) was used to quantify the littoral zone. The 2001 bathymetric survey was delivered as a contour map, divided into 10 m intervals. To identify the 6-m littoral zone the coarse historical pre-breach survey data was up-sampled to 1 m intervals and the area from 0 to 6 m depth was combined to represent the littoral zone. A constant nearshore slope was assumed in up-sampling.

This methodology includes assumption of constant nearshore slope in the up-sampling and definition of the pre-TSF failure littoral areas. In addition, pre-TSF failure data offer coarse spatial resolution and are not suited to detailed analyses. These data are the only available pre-TSF failure bathymetric data and enabled estimation of littoral habitat permanently altered. However, the accuracy of resultant values is only comparable to the accuracy of the original survey and any corresponding interpolation conducted to produce contours of 10 m intervals.

[1] Scale of 1:100,000. Sounding line spacing of 1,000 m.

The length of shoreline in the West Arm of Quesnel Lake and the length of shoreline affected by the TSF dam failure were compared to determine the proportion of shoreline affected by the TSF dam failure. Shoreline data used to define the shoreline position within the West Arm of Quesnel Lake was derived from Coast Pilot (2001). The length of shoreline affected was defined by the length adjacent to identified regions of tailing deposits at the terminus of Hazeltine Creek. This extent was defined by the Hazeltine Creek Hydrotechnical and Geomorphological Impact Assessment (SNC-Lavalin 2015b).

Polley Lake

At the time of preparing this FFHIA There was no information that identified the Polley Lake shoreline or lake bed pre- or post-TSF dam failure. Therefore, only a qualitative review of potential changes in physical properties of fish habitat was completed.

3.3 Assumption

One key assumption used throughout this assessment is that observable or inferred changes in the vital rates (e.g., survival or reproduction) of species are ultimately related to population viability and fishery sustainability (Randall et al. 2013; Koops et al. 2013). For example, the observation of restricted access to spawning habitat was considered evidence to suggest a future reduction in population productivity, and thus some negative effect on fish production.

4 FISHERIES BASELINE CONDITIONS

The fisheries baseline information was compiled during a desk-top study of best available scientific information and professional opinion and draws where necessary on available information and/or findings from the Water Quality Impact Assessment (WQIA; Golder 2015a), Sediment Impact Assessment (Minnow Environmental 2015), Hydrotechnical and Geomorphological Impact Assessment (SNC-Lavalin 2015b) and the Bathymetry Analysis and Volume Balance (Tetra Tech, Inc. [Tetra Tech] 2015).

For each of the sections below the pertinent baseline information has been summarized for each watercourse and waterbody. This includes: characterization of fish habitat, description of fish species assemblage including the identification of federal and provincial at-risk fish species. For a summary of life histories for select fish species that inhabit Hazeltine and Edney creeks refer to Appendix II.

4.1 Hazeltine Creek

Hazeltine Creek is a 10.3 km-long, third-order (describes the relative size and topology of a stream in a network; RISC 2001) watercourse that flows southeast from Frypan Lake to Polley Lake and eventually draining to the West Arm of Quesnel Lake (BC MoE 2014). Hazeltine Creek has at least 14 tributaries including Edney and Bootjack creeks, and drains an area of approximately 112 km^2 in the Cariboo region of BC (Minnow Environmental 2014).

4.1.1 Biophysical and Fish Habitat Characteristics

Minnow Environmental (2007) conducted the most detailed fish and fish habitat study available for Hazeltine Creek. The study area consisted of nine surveyed reaches, which extended from a point approximately 1.75 km downstream of the Polley Lake outlet to the confluence of Quesnel Lake and provided a summary of the biophysical assessment and habitat characteristics of each designated reach (Minnow Environmental 2007).

The following general summary of the biophysical assessment is from the Minnow Environmental Aquatic Environmental Description Report (Minnow Environmental 2014):

Most of Hazeltine Creek has a moderate gradient (less than 2%) with the exception of a steep section (7.3% gradient) approximately 5.8 to 7.0 km downstream of Polley Lake. Stream morphology is mostly riffle-run with flow typically confined within a well-defined meandering channel with predominantly gravel-cobble substrate and bordered by relatively steep banks. Morphology of the steep section is step-pool, with a dominance of cobble to bedrock substrate. A few depositional locations typically associated with beaver activity have been identified within Hazeltine Creek. The steep section located in reaches 5 and 6 presents a barrier to fish passage. Due to the fish barrier fish from Quesnel Lake cannot access the upstream areas of Hazeltine Creek and Polley Lake.

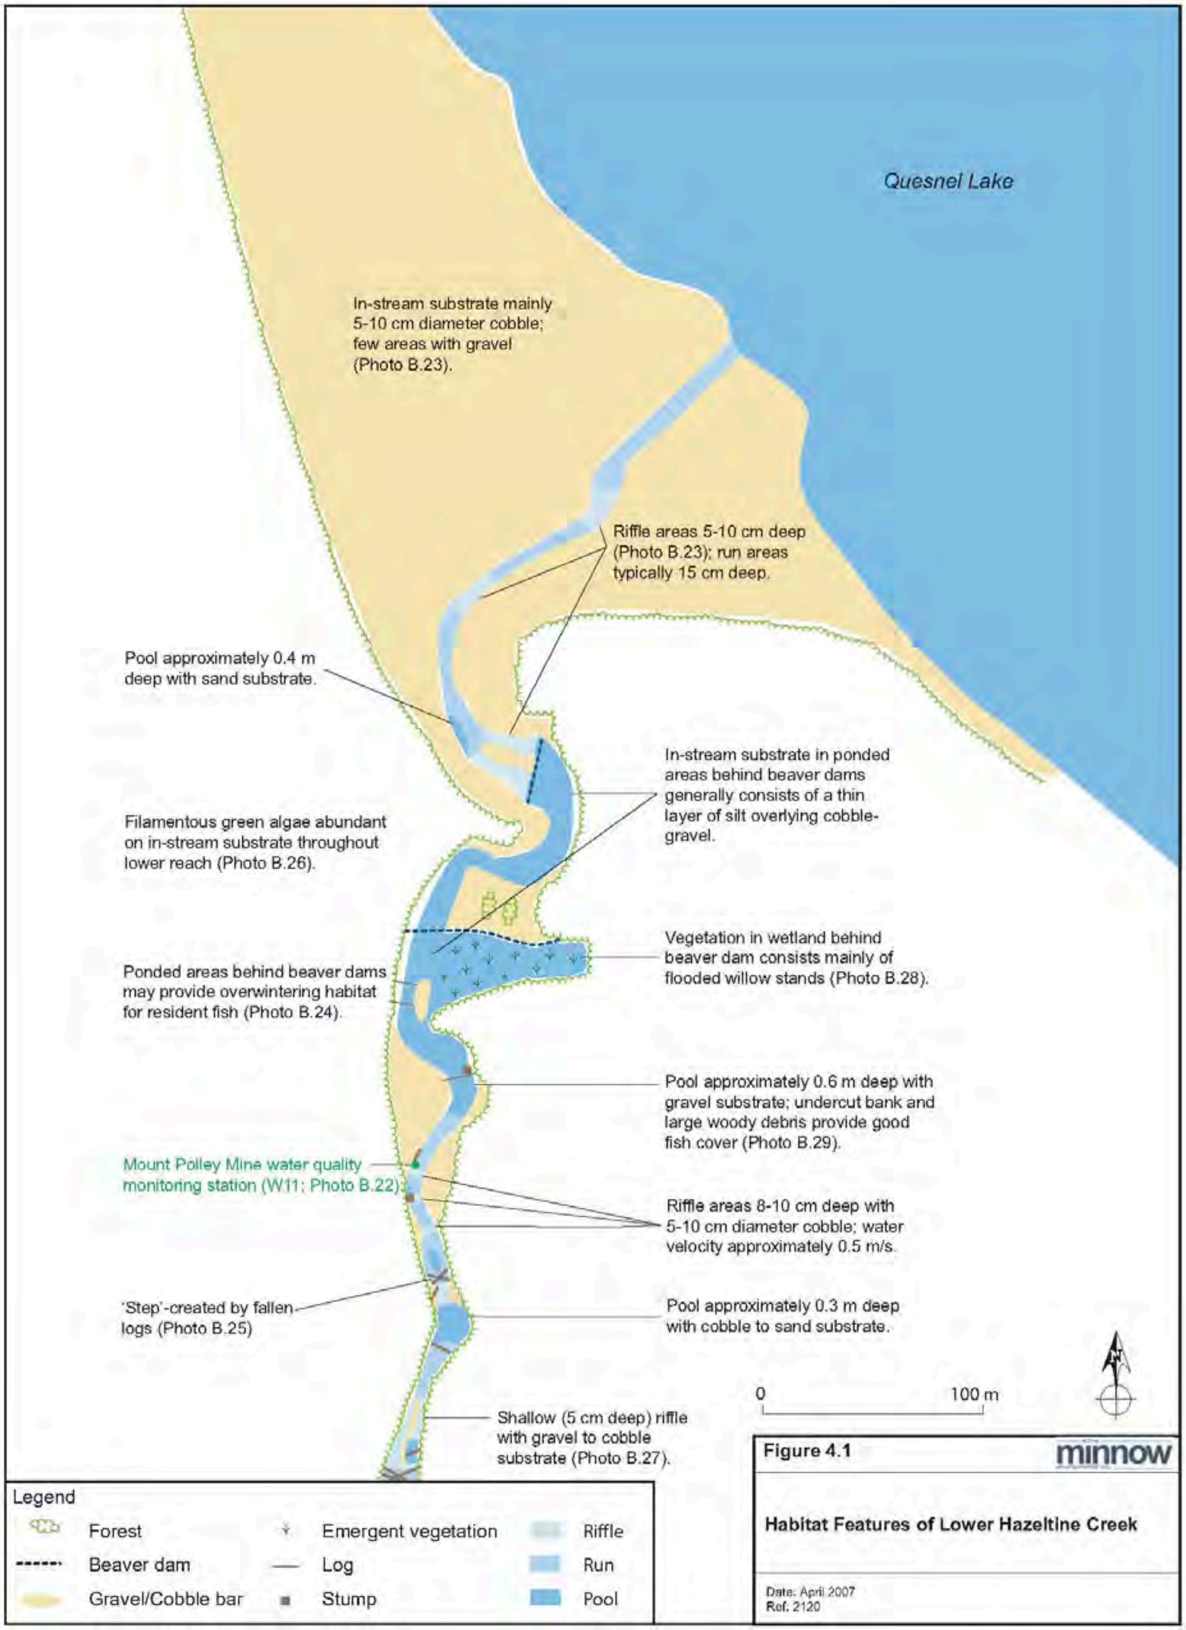
Delineation of the reaches identified for Hazeltine Creek are shown in Figure 3.2 (taken from Minnow Environmental 2014).

Overall, Hazeltine Creek was dominated by shallow riffle/run mesohabitat with some limited pool habitat (Minnow Environmental 2007). Functional aquatic cover was provided mainly by large woody debris (LWD), overhanging vegetation, and pool depth. The proportion of functional aquatic cover, particularly deep pool habitat, was relatively low in Hazeltine Creek (Minnow Environmental 2007). As such, suitable overwintering habitat for sub-adult/adult salmonids was limited. Some pools identified as suitable overwintering habitat were associated with the presence of beaver dams (Minnow Environmental 2007).

Hazeltine Creek from Quesnel Lake upstream to the confluence with Edney Creek has been identified in the Horsefly Sustainable Regional Management Plan (HSRMP) as critical habitat (BC MFLNRO 2005). The HSRMP is one of seven plans covering the Cariboo-Chilcotin Region, including the previously endorsed South Chilcotin and Anahim Round Table plans. SRMPs are a spatial application of the Cariboo Chilcotin Land Use Plan (CCLUP) direction at the sub-regional planning level. The assessment area lies within the boundaries of this plan; the FFHIA was informed by the fisheries management information presented in this plan.

Figure 3.2: Hazeltine Creek Habitat Survey

Although species considered in the HSRMP included Salmon, Bull Trout, Rainbow Trout (*O. mykiss*), and Kokanee (*O. nerka*), the Plan did not specifically identify which species the critical habitat of Hazeltine applied to (BC MFLNRO 2005). Minnow Environmental (2007) also characterized fish habitat in Hazeltine Creek near the confluence of Quesnel Lake (Figure 4-1, on the following page). And more recently, as part of a foreshore inventory and mapping assessment, the mouth of Hazeltine Creek was assigned a 'Very High' aquatic habitat index rating by Ecoscape Environmental Consultants (Ecoscape 2012). The rating was based on four parameters (biophysical, fisheries, shoreline vegetation and habitat modification), which were integrated into a scoring system based on data collected during the assessment, and each of the four parameters was given a score based on the physical properties of the assessed area. The aquatic habitat index ratings range from 'Very Low' to 'Very High' based on fish and wildlife habitat values (e.g., presence of aquatic vegetation) (Ecoscape 2012).



Fiigure 4-1: Habitat Feature of Lower Hazeltine Creek

4.1.1.1 Riparian Habitat

Riparian habitat along Hazeltine Creek consisted of conifers (western redcedar, fir, sitka spruce, western hemlock), deciduous (alder, black cottonwood, Pacific willow) and shrubs (hardhack, red-osier dogwood) (Minnow Environmental 2007). Approximately 22% of the overhead canopy cover throughout the nine surveyed reaches was considered dense (greater than 70% of stream surface area shaded), 27% was partially open (10-70% of stream shaded), and 48% open (less than 10% of stream shaded) (Minnow Environmental 2007).

No specific characteristics with respect to aquatic or riparian habitat were available for the uppermost-segment of Hazeltine Creek (from the outlet of Polley Lake downstream to a distance of 1.75 km).

4.1.2 Fish Assemblage

With the presence of a barrier that prevents upstream migration of fish on Hazeltine Creek (approximately 2.6 km upstream of Quesnel Lake), there were two unique fish assemblages: Upper Hazeltine Creek and Lower Hazeltine Creek.

4.1.2.1 Upper Hazeltine Creek

Rainbow Trout appear to be the only commercial, recreational or Aboriginal fishery species to inhabit upper Hazeltine Creek (Minnow Environmental 2014).

Upper Hazeltine Creek provided important spawning habitat for Rainbow Trout from Polley Lake, with adults migrating to spawn in the creek between early May and early June (MPMC 2004; Minnow Environmental 2014). Typically, after freshet when flows have subsided, adults, along with parr from the previous spawning season, return to Polley Lake. The emigration of larger fish shortly after freshet is reflected in data collected by Bruce and Slaney (1991) and Minnow Environmental (2009), as the vast majority of Rainbow Trout collected in upper Hazeltine Creek consisted of young-of-the-year (YOY). A summary of capture results for Rainbow Trout from upper Hazeltine Creek are provided in Table 4-1.

Table 4-1: Summary of Rainbow Trout Capture Data from Upper Hazeltine Creek

Watercourse	Year	Species	Age	Number Captured	Mean Fork Length (mm)	Mean Weight (g)
Upper Hazeltine Creek	1989[1]	Rainbow Trout	-	48	-	-
	1990[2]		0^+	612	41	0.90
			1^+	3	91	8.43
			2^+	1	143	36.05
	2007[3]		0-1	198	48.4[5]	1.49[5]
	2012[4]		-	20	281	241

[1] data from Imperial Metals (1990); MPMC (2009).
[2] data from Bruce and Slaney (1991).
[3] data from Minnow Environmental (2009) (data combined for three sites); Cariboo Envirotech (2008a).
[4] data from Minnow Environmental (2012).

Estimates of Rainbow Trout relative abundance in upper Hazeltine Creek ranged from 3.64 to 7.04 fish/60 electrofishing seconds (Minnow Environmental 2009; Table 4-2). Potential recruitment of Rainbow Trout from upper Hazeltine Creek to Polley Lake has been estimated to be approximately 54,500 individuals annually (Bruce and Slaney 1991).

Table 4-2: Estimated Rainbow Trout Relative Abundance from Upper Hazeltine Creek

Location	Year	Station	Relative Abundance Catch Per Unit Effort (# of fish / 60 EF seconds)
Upper Hazeltine Creek	2007[1]	UHC-1	3.90
		UHC-2	7.04
		UHC-3	3.64

[1] data from Minnow Environmental 2009. UHC=Upper Hazeltine Creek.

4.1.2.2 Lower Hazeltine Creek

Fish species diversity in lower Hazeltine Creek (i.e., downstream of the cascade barriers) is considerably more diverse, likely due to accessibility from Quesnel Lake. Table 4-3 summarizes the documented species in lower Hazeltine Creek.

Table 4-3: Fish Species Documented in Lower Hazeltine Creek

Species Groupings	Common Name	Latin Name
Salmonids	Sockeye Salmon	*O. nerka*
	Coho Salmon	*O. kisutch*
	Chinook Salmon	*O. tshawytscha*
	Kokanee	*O. nerka*
	Rainbow Trout	*O. mykiss*
	Mountain Whitefish	*P. williamsoni*
Non-Salmonids	Burbot	*Lota lota*
	Largescale Sucker	*C. macrocheilus*
	Longnose Sucker	*C. catostomus*
	Longnose Dace	*Rhynichthys cataractae*
	Peamouth	*Mylocheilus caurinus*
	Redside Shiner	*Richardsonius balteatus*

Few studies have been conducted on lower Hazeltine Creek. Rainbow Trout and Burbot appear to be the most common species of fish inhabiting this section of the creek, as the remaining species, have been caught in relatively low numbers (Imperial Metals 1990; MPMC 2009; Minnow Environmental 2009; Cariboo Envirotech 2008a) (Table 4-4).

Table 4-4: Summary of Fish Capture Data in Lower Hazeltine Creek

Year	Species	Number Captured
1989[1]	Chinook Salmon	9
	Longnose Sucker	8
	Rainbow Trout	142
	Sockeye Salmon	8
	Mountain Whitefish	2
2007[1,2]	Bridgelip Sucker	6
	Burbot	158
	Chinook Salmon	38
	Coho Salmon	9
	Largescale Sucker	9
	Longnose Dace	24
	Peamouth	18
	Redside Shiner	6
	Rainbow Trout	96
	White Sucker	1

[1] data from Imperial Metals (1990); MPMC (2009).
[2] data from Minnow Environmental (2009) (data combined for three sites); Cariboo Envirotech (2008a).

Relative abundance data for fish was sparse for lower Hazeltine Creek (Table 4-5).

Table 4-5: Summary of Relative Fish Abundance in Lower Hazeltine Creek

Location	Year	Station	Relative Abundance Catch Per Unit Effort (# of fish/60 electrofishing seconds)						
			Rainbow Trout	Burbot	Chinook Salmon	Coho Salmon	White Sucker	Longnose Dace	Bridgelip Sucker
Lower Hazeltine Creek[1]	2007[1]	LHC-1	0.83	1.53	0.30	0.07	-	0.08	0.05
		LHC-2	0.55	0.55	0.18	-	-	-	-
		LHC-3	0.56	1.21	0.36	0.02	0.02	0.02	-

[1] data from Minnow Environmental 2009. LHC=Lower Hazeltine Creek.

A small escapement data set was available for Sockeye and Coho Salmon for lower Hazeltine Creek. Mean annual escapement from Hazeltine Creek between 1989 and 2013 was 280 adult Sockeye, with a high of 1,616 observed in 1989 (DFO 2015). In 2006 (Minnow Environmental 2007) and in 2010 (DFO 2015), no Sockeye were observed, whereas 79 were documented in 2011.

Coho Salmon have also been documented in Hazeltine Creek; however, limited numbers have been observed. Four adult Coho were observed within 125 m of Edney Creek confluence in November 2007, while none were documented in 2008 (Cariboo Envirotech 2008a; 2009). Fish life history summaries for species that are present in Hazeltine Creek are presented in Appendix II.

4.2 Edney Creek

Edney Creek is a 13.16 km-long, third-order (describes the relative size and topology of a stream in a network; RISC 2001) watercourse that flows southeast from Edney Lake to Hazeltine Creek, which drains to Quesnel Lake (BC MoE 2014; Minnow 2007). Edney Creek has approximately 12 tributaries and drains an area of approximately 86 km2 in the Cariboo region of BC (Pederson 1998).

4.2.1 Biophysical and Fish Habitat Characteristics

A habitat impact study conducted at a site on lower Edney Creek (F1) at the Horsefly-Likely Forest Service Road (FSR) crossing in 1995 found usable Rainbow Trout fry habitat (49% of total area) as well as juvenile habitat (39% of total area), based on the discharge at the time of the survey (Hallam Knight Piésold 1996a).

A fisheries monitoring program conducted in 1997 reported that the site (F1) consisted of a variety of substrates, with run mesohabitat predominant (50%); however, riffle (30%) and pools (20%) were also present (Hallam Knight Piésold 1997). Aquatic cover types were well mixed, with the total aquatic cover in the channel at approximately 25%.

Pederson (1998) classified lower reaches of Edney Creek as having a cascade-pool morphology dominated by cobble substrates, with functioning LWD as the most prevalent aquatic cover type. Fish habitat value was rated as high.

In 2006, Edney Creek was observed to be ponded just upstream from its confluence with Hazeltine Creek due to the presence of a beaver dam, which resulted in Edney Creek splitting into two channels that both flowed into Hazeltine Creek (Minnow Environmental 2007). This same assessment concluded that Edney Creek contributed approximately 60% of the flow into lower Hazeltine Creek below the Edney/Hazeltine Creek confluence.

In 2007, a salmon spawning assessment was completed for the first 600 m of Edney Creek from the Hazeltine Creek confluence (shown on Map 1, Cariboo 2009). Results characterized spawning habitat quality as high due to deep pools, abundant aquatic cover, and presence of suitable spawning gravels (Cariboo Envirotech 2008a).

4.2.2 Fish Assemblage

At least nine fish species have been documented in Edney Creek (BC MoE 2014; Cariboo Envirotech 2008a; Hallam Knight Piésold 1997). Table 4-6 summarizes the documented species in Edney Creek.

Table 4-6: Fish Species Documented in Edney Creek

Species Groupings	Common Name	Latin Name
Salmonids	Sockeye Salmon	*O. nerka*
	Coho Salmon	*O. kisutch*
	Chinook Salmon	*O. tshawytscha*
	Rainbow Trout	*O. mykiss*
	Mountain Whitefish	*P. williamsoni*
Non Salmonids	Burbot	*L. lota*
	Longnose Sucker	*C. catostomus*
	Longnose Dace	*R. cataractae*
	Redside Shiner	*R. balteatus*

Table 4-7 summarizes fish capture data from historical sampling programs for Edney Creek.

Table 4-7: Summary of Historical Fish Capture Data in Edney Creek

[3] data from DWB (2014).
[4] data from Minnow Environmental (2009).
[5] data from Cariboo Envirotech (2008a).
[6] data only from 100 Rainbow Trout.
'-' = data not available.

Although Sockeye, Coho, and Chinook Salmon have been documented in Edney Creek, spawner escapement data is not available. The number of Coho Salmon observed in Edney Creek is small and has ranged from 0 individuals recorded in 2008 (Cariboo Envirotech 2009) to a maximum of 12 individuals in 2007 (Cariboo Envirotech 2008a). No juvenile Coho Salmon have been documented (Hallam Knight Piésold 1997; Minnow Environmental 2009). Sockeye Salmon have also been observed; however, their only documented presence was in 1989.

Of the fish species present in Edney Creek, only Rainbow Trout and Longnose Sucker have been captured in the upper section of the watercourse (i.e., near Edney Lake and in tributaries). The upper limit of fish distribution in Edney Creek is likely a falls barrier of unknown height located upstream of Edney Lake (Hallam Knight Piésold 1997; BC MoE 2014). Rainbow Trout and Redside Shiner are documented to be present in Edney Lake (BC MoE 2014). Adult Rainbow Trout and Longnose Sucker likely utilize Edney Lake for rearing and spawn in the creek, with juveniles utilizing the Edney Creek mainstem as rearing habitat (MPMC 2009). Redside Shiner may also spawn in Edney Creek, but some populations also spawn in lakes (McPhail 2007).

Data from a study conducted in lower Edney Creek indicated that ages for Rainbow Trout ranged from YOY to three-year-olds (Hallam Knight Piésold 1997). Rainbow Trout age from studies in 1997 and 2007 in upper Edney Creek and two of its tributaries were similar to those in the lower section (YOY to three-year-olds) (Hallam Knight Piésold 1997; Minnow Environmental 2009).

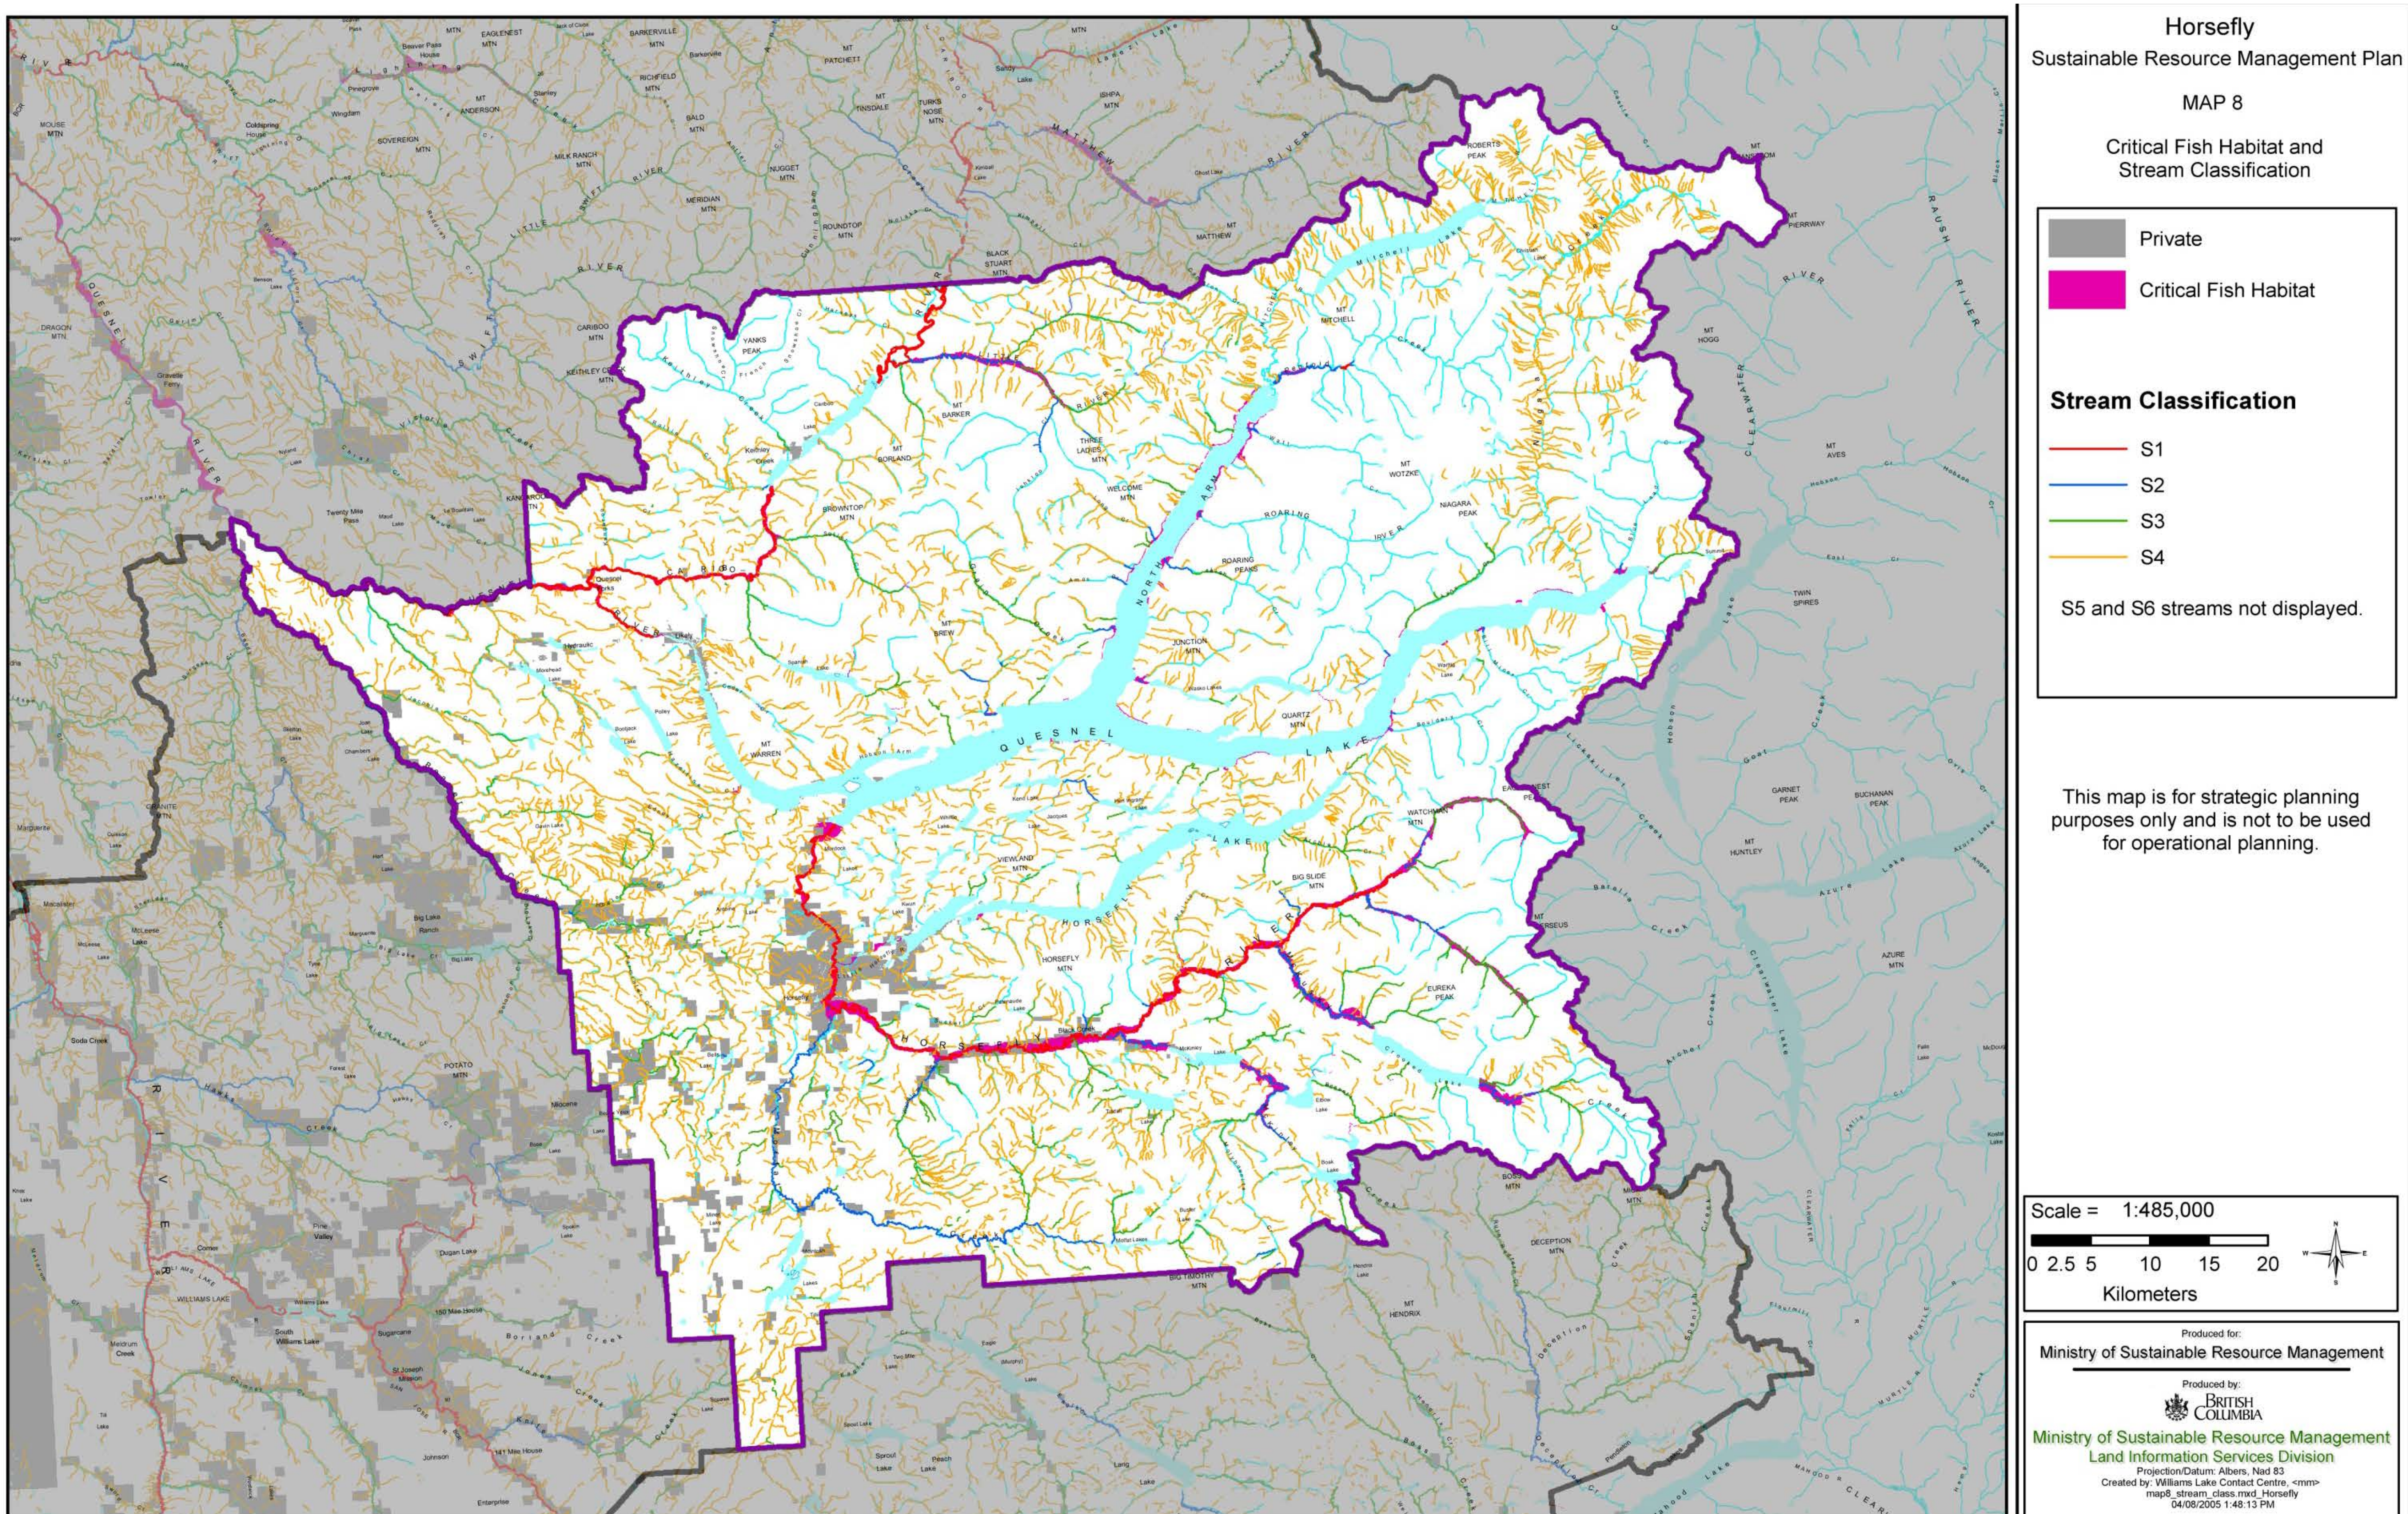
Based on 2007 data, the majority of Rainbow Trout captured in upper Edney Creek (79%) were YOY (Minnow Environmental 2009). Fish life history summaries for species that are present in Edney Creek are presented in Appendix II.

4.3 Quesnel River

Quesnel River is a fifth-order (describes the relative size and topology of a stream in a network; RISC 2001) watercourse that flows from Quesnel Lake at the town of Likely, approximately 100 km northwest toward the city of Quesnel, where it discharges into the Fraser River. Quesnel River is the only discharge channel of Quesnel Lake and has a mean annual outflow of approximately 131 m^3/s (Orbis 2009). The Quesnel watershed occupies 225,751 hectares (ha) in south central BC and provides migration, rearing and spawning habitat for several salmonid and non-salmonid species (Pederson 1998). The Quesnel watershed consists of four smaller watersheds including the Cariboo River, Cottonwood River, Quesnel River and Horsefly River (Orbis 2009).

4.3.1 Biophysical and Fish Habitat Characteristics

The mainstem of the Quesnel River provides valuable habitat for numerous life stages for a number of salmonid and non-salmonid species (Pederson 1998). The HSRMP (BC MFLNRO 2005) identified critical fish habitat on Quesnel River, Figure 4-3 (Map 8). Specifically, Quesnel River is considered critical habitat for Quesnel Lake Rainbow Trout, a river resident stock (Sebastian et al. 2003) believed to use the Quesnel River for spawning. The West Arm of Quesnel Lake has important salmonid habitat areas, which have experienced anthropogenic impacts prior to the TSF dam failure, particularly near the Quesnel River confluence (Ecoscape 2012).



Map 8: Horsefly Sustainable Resource Management Plan

Limited detailed fish habitat information has been documented for the upper section of Quesnel River near Quesnel Lake. However, mesohabitats in the Quesnel River were generally described by Cariboo Envirotech (2007; 2008b), and included:

- Non-turbulent glides at the outlet of Quesnel Lake (referred to as the 'Narrows') and low gradient pools as the river widens near the town of Likely.
- Faster water with riffles and cascades throughout the area between the Likely bridge and the UNBC Quesnel River Research Centre.
- Fast moving water with steep gradients and high canyon walls in the section of river between the UNBC Quesnel River Research Centre to the Bullion Pool (approximately 4.4 km downstream from the Likely bridge).
- Wide, fast flowing water downstream of the Bullion Pool is the Quesnel Forks where the Cariboo and Quesnel rivers converge.

4.3.2 Fish Assemblage

Numerous fish species have been documented in Quesnel River (BC MoE 2014). Table 4-8 summarizes the documented species.

Table 4-8: Fish Species Documented in Quesnel River

Species Groupings	Common Name	Latin Name
Salmonids	Sockeye Salmon	*O. nerka*
	Coho Salmon (IFC)	*O. kisutch*
	Chinook Salmon	*O. tshawytscha*
	Pink Salmon	*O. gorbuscha*
	Rainbow Trout	*O. mykiss*
	Mountain Whitefish	*P. williamsoni*
	Dolly Varden	*S. malma*
	Bull Trout	*S. confluentus*
	Lake Trout	*S. namaycush*
	Kokanee	*O. nerka*

Table 4-8 (Cont'd): Fish Species Documented in Quesnel River

Species Groupings	Common Name	Latin Name
Non Salmonids	Burbot	*L. lota*
	Longnose Sucker	*C. catostomus*
	Longnose Dace	*R. cataractae*
	Leopard Dace	*Rhinichthys falcatus*
	Largescale Sucker	*C. macrocheilus*
	Northern Pikeminnow	*Ptychocheilus oregonensis*
	Redside Shiner	*R. balteatus*
	Slimy Sculpin	*Cottus cognatus*
	Sculpin (general)	-
	Sucker (general)	-
	Sturgeon (general)	-
	Lamprey (general)	-
	Minnow (general)	-

Sport fish in Quesnel River include Chinook and Coho Salmon as well as resident Kokanee, Rainbow Trout, Lake Trout, Dolly Varden, Whitefish, and several pelagic non-salmonid species (Imperial Metals 1990). Below is a summary of fish species that utilize the upper Quesnel River as part of their life history.

Sockeye Salmon utilize Quesnel River during migration to/from Quesnel Lake.

Kokanee also utilize the narrows of Quesnel River near the town of Likely for spawning (Pederson 1998). The Horsefly River and Quesnel River Kokanee spawning runs are nearly a month earlier than Quesnel Lake shore spawning Kokanee but 10 days later than Sockeye (Sebastian et al. 2003).

Rainbow Trout are the most common species inhabiting the upper Quesnel River (UFFCA & DFO 2010) and spawn downstream of Quesnel Lake to the UNBC Quesnel River Research Centre (Previously Likely Fish Hatchery) (Pederson 1998). The Quesnel River Rainbow Trout are a river resident stock (Sebastian et al. 2003).

Interior Fraser Coho Salmon are part of a population that are listed as "endangered" by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) and are under consideration for listing under the federal *Species at Risk Act* (SARA 2002). A small subset of the population spawns in Quesnel River downstream of Quesnel Lake to the UNBC Quesnel River

Research Centre (Pederson 1998). Although no historical Coho Salmon stocking or spawner escapement data is available (DFO 2015), twenty-seven percent of the 530 Coho observed during a 2007 adult Coho survey were observed in Quesnel River (n=131) and Quesnel River narrows (n=13) (Cariboo Envirotech 2008a). No Coho (live or deceased) were observed in any of the watercourses surveyed in 2008 (Cariboo Envirotech 2009); however, this may be attributed to the surveys being conducted later in the season than previous years.

Chinook Salmon spawn in the narrows of Quesnel River and at the bridge near Likely (Pederson 1998). Chinook Salmon spawner escapement data have been collected in Quesnel River since 1951 (DFO 2015). Mean annual escapement over 63 sampling periods between 1951 and 2013 was 2,084 adult Chinook, with a high of 9,000 observed in 1986 (DFO 2015).

Pink Salmon are limited to the lower section of the Quesnel River as the canyon upstream of the Barlow Creek and Quesnel River confluence is a gradient barrier for this species (Pederson 1998). Pink Salmon spawner escapement data have been collected intermittently in Quesnel River since 1965 (DFO 2015). Mean annual escapement over 11 sampling periods between 1985 and 2013 was 1,449 adult Pink, with a high of 4,000 observed in 1971 (DFO 2015).

Dolly Varden spawn in Quesnel River from the Likely bridge downstream to the UNBC Quesnel River Research Centre (Pederson 1998).

4.4 Quesnel Lake

Quesnel Lake, BC's deepest lake and one of the deepest fjord lakes in the world, is a glacial lake with a reported maximum depth of 610 m (Cariboo Envirotech 2008a), with an estimated maximum depth of 116 m recorded for the West Arm (Coast Pilot 2001). The approximate surface area of West Arm is about 21.5 km^2 with a volume of approximately 1 km^3. The lake is dimictic and oligotrophic. Occasionally the lake freezes over during winter while summer surface water temperature seldom exceeds 18ºC. The lake is fed by several tributaries, with primary influence being from Horsefly River, Mitchell River, and Niagara Creek, and drains via Quesnel River to the Fraser River (MPMC 2009). Portions of the Cariboo Mountains Provincial Park are adjacent to the eastern section of the lake along the north and east arms; the town of Likely, BC is present near the outlet at the west arm.

4.4.1 Fish Assemblage

At least 20 fish species have been documented in Quesnel Lake including several migratory salmonids, resident salmonids, benthic and pelagic non-salmonid species (Bryant et al. 1996, Hatfiled 1996, McPhail 2007; Table 4-9).

Table 4-9: Fish Species Documented in Quesnel Lake

Species Groupings	Common Name	Latin Name
Migratory salmonids	Sockeye Salmon	*O. nerka*
	Coho Salmon	*O. kisutch*
	Chinook Salmon	*O. tshawytscha*
Resident salmonids	Kokanee	*O. nerka*
	Rainbow Trout	*O. mykiss*
	Bull Trout	*S. confluentus*
	Lake Trout	*S. namaycush*
	Pygmy Whitefish	*Prosopium coulteri*
	Mountain Whitefish	*P. williamsoni*
	Lake Whitefish	*Coregonus clupeaformis*
Benthic species	Burbot	*L. lota*
	Largescale Sucker	*C. macrocheilus*
	Longnose Sucker	*C. catostomus*
	Slimy Sculpin	*C. cognatus*
Pelagic non-salmonid species	Northern Pikeminnow	*P. oregonensis*
	Peamouth Chub	*M. caurinus*
	Leopard Dace	*R. falcatus*
	Longnose Dace	*R. cataractae*
	Redside Shiner	*Richardsonius balteatus*
	Lake Chub	*Couesius plumbeus*

The main emphasis of studies conducted on Quesnel Lake has been on the food web interactions between Sockeye Salmon/Kokanee and Rainbow Trout (Sebastian et al. 2003; Parkinson et al. 1989; Selbie 2014), as well as DFO trawl surveys specifically targeting juvenile Sockeye and Kokanee in the limnetic zone of the lake. Other limited information for Quesnel Lake fisheries was obtained through multiple fish creel surveys conducted between 1950s and 1970s. As such, the majority of assessments in Quesnel Lake pertain to species of fish of commercial, Aboriginal and/or recreational value. Based on the available information, relatively little is known about the specific distribution of fish species within Quesnel Lake, particularly benthic and pelagic, non-salmonid species. These species are typically caught as by-catch and are rarely targeted by fishery or research programs.

The descriptions provided below provide some general information for species of fish considered to be a part of a commercial, recreational or Aboriginal fishery for which studies have been conducted.

Sockeye Salmon are an important fishery, migrating from the Fraser River up the Quesnel River, and into Quesnel Lake and tributaries. Over 80 Sockeye Salmon populations have been identified in Quesnel Lake with spawning primarily occurring in the Horsefly and Mitchell river systems, as well as in several other smaller tributaries and along the shoreline in parts of Quesnel Lake (UFFCA & DFO 2010). Sockeye Salmon spawner escapement data have been collected intermittently from numerous tributaries and lake shore areas of Quesnel Lake between 1950 and 2013 (DFO 2015) (Table 4-10). None of the specific shore spawning locations identified in Table 4-10 are in proximity to Hazeltine Creek, as they are primarily located in the North Arm of Quesnel Lake.

Table 4-10: Documented Sockeye Salmon Shoreline Spawning Areas in Quesnel Lake

Location on Quesnel Lake	Mean Escapement Estimate (and Range)	Number of Sampling Years (Year Range)
Deception Point	11,656 (0-123,709)	19 (1990-2013)
North Arm – unnamed cove	1,651 (0-7,184)	8 (2001-2011)
Goose Point	1,613 (0-16,202)	12 (1999-2013)
Long Creek – lake shore	1,454 (0-5,920)	10 (1999-2013)
Blue Lead Creek – lake shore	1,271 (0-11,173)	13 (1999-2013)
Grain Creek – lake shore	1,214 (0-7,371)	12 (1999-2013)
Bear Beach – lake shore	1,156 (0-8,797)	8 (1999-2013)
Bowling Point	1,135 (0-11,160)	11 (1999-2013)
Roaring River – lake shore	1,008 (0-7,632)	14 (1999-2013)

Coho Salmon present in Quesnel Lake are part of the IFC population that is listed as "endangered" by COSEWIC and are under consideration for addition to the SARA (GoC 2014). A small subset of the population spawns in Quesnel River and several other tributaries to Quesnel Lake (Cariboo Envirotech 2008a). Although few individuals have been documented in Edney and Hazeltine Creek, these watercourses do provide some suitable spawning habitat.

Kokanee in Quesnel Lake have two distinct populations; tributary spawners and shoreline spawners (Sebastian et al. 2003). The estimated Kokanee spawning population of Quesnel Lake was between 75,000 and 150,000 individuals, with the majority being shoreline spawners (Sebastian et al. 2003). Although few known shore spawning locations have been identified in Quesnel Lake, several locations have been documented in the north and east arms (Deception Point, Blue Lead Creek, and Goose Point) (Sebastian et al. 2003). Limited information is available for shore spawning locations in the West Arm and it is unknown whether Kokanee utilize Hazeltine Creek or the lake shore area in the vicinity of the Hazeltine Creek-Quesnel Lake confluence.

Rainbow Trout in Quesnel Lake can attain 7-10 kilogram (kg) in size and are part of a renowned recreational fishery. Few Rainbow Trout studies have been conducted on the lake itself (most pertain to food web implications with Kokanee/Sockeye Salmon), but rather have focused on spawning surveys in some of the major tributaries: Mitchell and Horsefly rivers. These two rivers have been identified as the major spawning locations for Quesnel Lake Rainbow Trout (Sebastian et al. 2003). Rainbow Trout are widespread in Quesnel Lake and often inhabit numerous smaller tributaries such as lower Hazeltine and Edney creeks (Lirette 2014).

4.5 Polley Lake

Polley Lake is located between Frypan Lake and Quesnel Lake in the Cariboo region of BC and is connected to these waterbodies by Hazeltine Creek. The lake is approximately 453 ha in size, with a maximum depth of 35 m and a mean depth of 18 m, with the deepest sections at either ends of the lake (BC MoE 2014; Minnow Environmental 2014). Total lake volume is estimated at 62.1 million m^3, and total watershed area (including lake area) is about 21.4 km^2 (Golder 2015c); however, the watershed was historically larger (21.63 km^2) prior to Mount Polley Mining Corporation diverting portions of the watershed for mine operations (Minnow Environmental 2014). Polley Lake's main inlet and outlet is Hazeltine Creek (BC MoE 2014); there are no other tributaries with year-round flow, but there are at least five other unnamed, seasonally-flowing tributaries that may be utilized by fish (i.e. Rainbow Trout) if conditions are suitable (MPMC 2004).

4.5.1 Biophysical and Fish Habitat Characteristics

Polley Lake is dimictic, with well-developed thermal stratification in summer that occurs at approximately 5 to 15 m (Minnow Environmental 2014). Although well-mixed in winter, water temperatures gradually increase with depth; whereas dissolved oxygen (DO) levels gradually decrease with depth, year-round. DO concentrations below 5.0 mg/L are typically observed at depths greater than 20 m during spring, summer and fall. An increase in the number of phytoplankton blooms supports a probable change in trophic status from oligotrophic/mesotrophic to mesotrophic/eutrophic based on recent (2012) observations.

No specific information was found describing fish habitat in Polley Lake; this represents a gap in the FFHIA.

4.5.2 Fish Assemblage

Polley Lake is a fish-bearing waterbody (BC MoE 2014; Minnow Environmental 2012); however, anadromous salmon are prevented from accessing the lake by a cascade barrier downstream on Hazeltine Creek. As such, there are no salmon spawner escapement data for Polley Lake. Resident species include Longnose Sucker and Rainbow Trout, which have been captured in Polley Lake during numerous fish surveys conducted for Mount Polley Mining Corporation between 1999 and 2012. Redside Shiners have been captured on occasion and most recently during field studies in 2014 after the tailings dam release (Lirette 2014). Table 4-11 summarizes the documented species in Polley Lake.

Table 4-11: Fish Species Documented in Polley Lake

Species Groupings	Common Name	Latin Name
Salmonids	Rainbow Trout	*O. mykiss*
Non Salmonids	Longnose Sucker	*C. catostomus*
	Redside Shiner	*R. balteatus*

Creel surveys conducted on Polley Lake in 1990 and 1995 estimated that 15,412 and 9,009 trout, respectively, were caught between May 1 and September 30; however, 1995 numbers may not be accurate due to the low number of surveys (n=2) (Lirette and Tredger 1991; Hallam Knight Piésold 1996b).

Adult Rainbow Trout migrate from Polley Lake to Hazeltine Creek after ice-out in the spring (mid-April to mid-May) to spawn, returning to the lake by mid-June near the end of freshet (MPMC 2004). The majority of Rainbow Trout fry present in Hazeltine Creek migrate to Polley Lake within their first year after hatching (i.e., as YOY) (Bruce and Slaney 1991). This is further substantiated by scale analysis of adult Rainbow Trout captured by anglers from the lake, which indicated that 82% were recruited to the lake as yearlings from their nursery stream (assumed to be Hazeltine Creek) (Lirette and Tredger 1991).

Bruce and Slaney (1991) estimated that approximately 54,500 Rainbow Trout fry and parr migrate to Polley Lake from Hazeltine Creek after hatching. Results suggest that Rainbow Trout from Hazeltine Creek contribute considerably to the overall Polley Lake recreational fishery.

Table 4-12 summarizes recent and historical catch results for fish captured in Polley Lake.

Table 4-12: Summary of Historical Fish Capture Data from Polley Lake

Site	Species	Year Sampled	Number Captured / Analyzed	Fork Length (mm)	Weight (g)	CPUE seine net (fish/ft^2/hour)
Polley Lake	Rainbow Trout	1973[1]	65	-	-	0.0008
		1990[1]	77	145 – 357	-	-
		1995[2]	16	230 – 300	213 – 303	0.0006
		2009/2010[3]	44	213 – 357	111 – 580	-
		2012[4]	30	280 – 399	105 – 650	0.0006

[2] data from Lirette and Tredger (1991).
[3] data from Hallam Knight Piésold (1996b).
[4] data from Minnow Environmental (2009).

4.6 At-Risk Species

There are no fish species documented in Hazeltine Creek, Edney Creek, Quesnel River, Quesnel Lake, nor Polley Lake, that are currently protected under the Government of Canada SARA (GoC 2014).

While there are no fish species considered ‘at risk’, local populations of Coho Salmon (IFC population) have been identified by COSEWIC as endangered. This particular Coho Salmon stock has periodically been observed in Hazeltine Creek and Edney Creek, and are known to be present in Quesnel Lake. However, the species is not currently listed on any Schedule under SARA and are therefore not protected under legislation (GoC 2014).

The BC MoE’s Species and Ecosystems Explorer was also accessed to obtain information on the presence of fish species at risk. The search results identified that Bull Trout are blue-listed (Special Concern) in the Cariboo Region, in which Quesnel Lake is located (BC CDC 2014). No other red- or blue-listed species were identified for the Cariboo Region. Bull trout are also listed by COSEWIC as a Species of Special Concern and under consideration for SARA designation.

5 IMPACT ASSESSMENT

5.1 *Hazeltine Creek*

5.1.1 Quantification of Habitat Footprints

5.1.1.1 Aquatic Habitat

Table 5-1 and Figure 5-1 (Appendix I) summarize the estimated aquatic habitat footprint on Hazeltine Creek (calculated as described in Section 3.2.1) that resulted from the TSF dam failure. Estimated areas are for each of the nine surveyed reaches of the creek, as well as for the unsurveyed section upstream of the nine reaches.

Table 5-1: Estimated Aquatic Habitat Altered in Hazeltine Creek

Watercourse	Reach	Channel (Bankfull) Width (m)[1,2,3]	Channel Length (m)	Aquatic Footprint (m^2)
Hazeltine Creek	u/s of Reach 1	6.2	1,900	11,765
	1	7.0	499	3,488
	2	45.0	231	10,186
	3	7.9	166	1,312
	4	4.7	2,488	11,690
	5	4.5	1,380	6,209
	6	3.7	1,120	4,133
	7	5.3	305	1,617
	8	5.0	703	3,509
	9	11.3	771	8,707
	Total	-	**9,563**	**62,616**

1 data from Minnow Environmental (2007).
2 reach 2 consisted of a ponded beaver dam area resulting in a larger channel (bankfull) width for this reach.
3 'u/s of Reach 1' channel width is the average width of Reaches 1 and 3-9. Reach 2 was not included as it consisted of a ponded beaver dam and considered an anomaly/outlier.

Approximately 62,616 m^2 of aquatic habitat were altered in Hazeltine Creek (from the outlet of Polley Lake to the inlet of Quesnel Lake) as a result of the TSF dam failure.

Table 5-2 summarizes the estimated aquatic habitat permanently altered by mesohabitat type (e.g., pool, riffle, run) and aquatic cover type (e.g., boulder, deep pool), as well as substrate class (e.g., sand, gravel) of the nine surveyed reaches of Hazeltine Creek.

Table 5-2: Estimates of Aquatic Habitat Type Altered in the Nine Surveyed Reaches of Hazeltine Creek by Habitat, Cover, and Substrate Type[1]

Watercourse	Mesohabitat Type	Area (m^2) of Mesohabitat Type and % of Total	Aquatic Cover Type	Area (m^2) of Aquatic Cover Type % of Total	Substrate Class	Area (m^2) of Substrate Type and % of Total
Hazeltine Creek	Pool	19,732 (39%)	Deep Pool	13,447 (60%)	Cobble	18,256 (45%)
	Run	16,871 (33%)	Large Woody Debris	4,413 (20%)	Gravel	14,227 (35%)
	Riffle	14,319 (28%)	Overhanging Vegetation	3,829 (17%)	Sand	5,675 (14%)
	-	-	Boulder	572 (3%)	Boulder	1,175 (3%)
	-	-	Other	174 (1%)	Fines	843 (2%)
	-	-	-	-	Bedrock	413 (1%)
	Total[2,3,4]	**50,851**	**-**	**22,435**	**-**	**40,589**

[1] data from Minnow Environmental (2007). Does not include section of Hazeltine Creek upstream of Reach 1.
[2] aquatic mesohabitat and substrate type totals do not equal, as Reach 2 did not have a substrate class recorded.
[3] aquatic cover type does not equal mesohabitat type or substrate class due to different analysis methods.
[4] totals may not equal due to rounding

Pool habitat comprised the largest (39%) mesohabitat type that was altered in the nine surveyed reaches of Hazeltine Creek. Of the available aquatic cover for fish, deep pools consisted of the greatest amount affected (60%), followed by LWD (20%) and overhanging vegetation (17%). Cobble (45%) and gravel (35%) were the two most dominant substrate types. No information is available for the impacted section of the creek upstream of the nine surveyed reaches (1.90 km). The mesohabitats comprising the uppermost reach of Hazeltine Creek between Reach 1 and Polley Lake outlet have not been accounted for in total areas/percentages summarized in Table 5-2 as detailed habitat data was not readily available in historical reports. However, given the reach's short linear distance, the numbers presented in Table 5-2 would not be expected to change substantially.

5.1.1.2 Riparian Habitat

Riparian habitat on both banks of Hazeltine Creek was permanently altered. Table 5-3 and Figure 5-1 (Appendix I) provide a summary of the estimated total riparian area (calculated as described in Section 3.2.1) that was affected along the nine surveyed reaches of the creek, including the unsurveyed section upstream of Reach 1 (Reach 1 to Polley Lake outlet).

Table 5-3: Estimated Riparian Habitat Altered Adjacent to Hazeltine Creek

Watercourse	Reach	Channel (Bankfull) Width (m)[1,2,3]	Riparian Management Area (m)[3,4]	Channel Length (m)[1]	Altered Riparian Area (m^2)[5]
Hazeltine Creek	u/s of Reach 1	6.2	50	1,900	179,804
	1	7.0	50	499	47,847
	2	45	70	231	23,061
	3	7.9	50	166	16,460
	4	4.7	40	2,488	168,731
	5	4.5	40	1,380	94,191
	6	3.7	40	1,120	51,988
	7	5.3	50	305	24,946
	8	5	40	703	50,244
	9	11.3	50	771	59,977
	Total[6]	-	-	**9,563**	**717,249**

1 data from Minnow Environmental (2007).
2 'u/s of Reach 1' channel width is the average width of Reaches 1 and 3 to 9. Reach 2 was not included as it consisted of a ponded beaver dam.
3 reach 2 consists of a ponded beaver dam area resulting in a larger bankfull (channel) width and RMA for this reach.
4 from edge of channel.
5 includes affected riparian area on both sides of Hazeltine Creek.
6 total affected riparian area does not include overlap on Edney Creek, so as not to double-count areas.

The total affected riparian area of Hazeltine Creek permanently altered as a result of the TSF dam failure was 717,249 m^2.

5.1.2 Potential Effects to Fish Productivity

Rainbow Trout was the only species known to utilize upper Hazeltine Creek, whereas Rainbow Trout and Burbot dominated fish catches in lower Hazeltine Creek. Although other species of fish have been documented in lower Hazeltine Creek, their presence is rare compared to that observed in other relatively nearby watercourses (e.g., Horsefly and Mitchell rivers), suggesting their contribution to overall productivity to each of those species in the Quesnel Lake system is expected to be limited. As such, the static values of relative abundance tabulated for lower Hazeltine Creek Rainbow Trout and Burbot are coarse estimates of overall productivity loss. Ideally, more dynamic parameters such as population estimates coupled with calculated production rates (e.g., Kwak 1992) would provide a more practical account of the affected productivity.

Rainbow Trout relative abundance in upper Hazeltine Creek typically ranged between 3.64 and 7.04 fish/60 electrofishing seconds (Table 5-4). Rainbow Trout relative abundance was considerably lower below the known fish barrier (i.e., lower Hazeltine) ranging between 0.55 to 0.83 fish / 60 electrofishing seconds. Relative abundance data for Burbot in lower Hazeltine Creek ranged from 0.55 to 1.53 fish/60 electrofishing seconds; Table 5-4).

Table 5-4: Estimated Fish Relative Abundance for Most Common Species Documented in Hazeltine Creek[1]

Watercourse	Year	Station	Fish Species	Relative Abundance (CPUE (# of fish/60 electrofsihing seconds)
Upper Hazeltine Creek	2007	UHC–1	Rainbow Trout	3.90
		UHC–2		7.04
		UHC–3		3.64
Lower Hazeltine Creek	2007	LHC-1	Rainbow Trout	0.83
		LHC-2		0.55
		LHC–3		0.56
		LHC–1	Burbot	1.53
		LHC–2		0.55
		LHC–3		1.21

[1] data from Minnow Environmental (2009).

Reaches 4 and 5 of Hazeltine Creek are historical identified spawning areas for Rainbow Trout from Polley Lake and is also considered important rearing habitat for juvenile Rainbow Trout (MPMC 2004). Bruce and Slaney (1991) estimated an annual recruitment of approximately 54,000 Rainbow Trout in upper Hazeltine Creek to Polley Lake using a theoretical density model developed by Ptolemy et al. (1991). Given this number was estimated prior to mine development it is unknown whether this estimate is indicative of upper Hazeltine Creek's production rate (productivity) at the time of the TSF dam failure.

5.1.2.1 Species and Life Stages Potentially Affected

5.1.2.1.1 Rainbow Trout

Rainbow Trout aging data from upper and lower Hazeltine Creek indicated that only YOY (0^+) and a few older fish (1^+) rear in Hazeltine Creek outside of the spawning window of April to late/May/early June (Minnow Environmental 2009; Bruce and Slaney 1991). Given that the TSF dam failure occurred in the month of August, it is believed that all YOY and juvenile Rainbow Trout were likely displaced as eggs typically hatch in late June after spring freshet (MPMC 2004). Considering adult Rainbow Trout return to their respective lake shortly after spawning in May/June, it is assumed that adults were likely not present in upper or lower Hazeltine Creek during the TSF dam failure, and thus were likely unaffected.

5.1.2.1.2 Pacific Salmon and Kokanee

Given the presence of a fish barrier in Hazeltine Creek, occurrences of Pacific Salmon and Kokanee are restricted to lower Hazeltine Creek. Three species of salmon have been documented in lower Hazeltine Creek and include Chinook, Coho, and Sockeye/Kokanee Salmon.

Adult Chinook return to their natal streams in the Quesnel Lake watershed as early as late July with the peak occurring in August (McPhail 2007). The displacement of juvenile Chinook Salmon is unknown but believed to be small given the low escapement numbers of the species in Hazeltine Creek.

Coho adults have been observed in Hazeltine Creek in November (Cariboo Envirotech 2008a), and due to their fall spawning time, were most likely not present during the TSF dam failure. The displacement of juvenile Coho Salmon, however, is unknown but believed to be small due to the low escapement numbers observed in Hazeltine Creek.

Sockeye Salmon and Kokanee have been documented in Hazeltine Creek and typically spawn in September/October. The spawning time of these species is considerably later than when the TSF dam failure occurred suggesting that adults were likely not present in Hazeltine Creek during the release. Potential displacement to juvenile Sockeye/Kokanee is also believed to be negligible given that fry migrate to their nursery lake shortly after emerging from the gravels.

5.1.2.1.3 Burbot & Mountain Whitefish

Burbot appeared to be one of the most abundant species of fish that was known to inhabit lower Hazeltine Creek. It is likely that only juvenile Burbot were displaced, as adults occupy deeper water during the summer months (i.e., Quesnel Lake) and 84% of captured fish in lower Hazeltine Creek were YOY (Minnow Environmental 2009).

Limited records document Mountain Whitefish in lower Hazeltine Creek, suggesting they account for a small percentage of the lower Hazeltine Creek fish assemblage. Based on the limited data, it is assumed that both juvenile and adult life stages, albeit few individuals, could have been displaced by the TSF dam failure.

5.1.2.1.4 Other Fish Species

Other than known presence and distribution information, abundance, and age data was not available for other fish species (see list in Table 4-3). However, all other species present in lower Hazeltine Creek (e.g., Redside Shiner, Longnose Dace, etc.) at the time of the TSF dam failure would have been displaced.

5.1.2.2 Potential Long-Term Implications

Table 5-5 summarizes the productivity components that were estimated to be as a result of the TSF dam failure. The TSF dam failure resulted in the temporary disruption to several productivity components; however, the long-term implications and overall disruption to productivity cannot be confirmed until rehabilitation efforts on Hazeltine Creek are complete.

Table 5-5: Summary of Productivity Components and Mechanisms for Reduced Productivity in Hazeltine Creek

Productivity Component	Mechanism for Reduced Productivity
Production	Disruption to production (e.g., habitat, fish abundance, diversity)
Growth	*Physiochemical water properties considered in Golder (2015)*
Individual performance	*Physiochemical water properties considered in Golder (2015).* Potential bioaccumulation considered in fish tissue memorandum '*Fish Tissue Results for Samples Collected Following the Mount Polley Tailings Storage Facility Dam Failure*' (SNC-Lavalin 2015a)
Survival	Displacement of fish *Physiochemical water properties considered in Golder (2015)*
Migration	Loss of access to key habitats
Reproduction	Loss of spawning events

Both the aquatic and riparian habitats of Hazeltine Creek were permanently altered. However, the duration and severity of the permanent alteration on overall fish production (including habitat) will depend on the nature and success of the rehabilitation (i.e., offsetting) efforts to altered riverine and riparian habitats. The level of permanent alteration should be re-evaluated once offsetting efforts in the immediately affected areas are complete and should be re-examined in the context of the results of any effectiveness and biotic-response monitoring.

Depending on when the affected segment of upper Hazeltine Creek is rehabilitated and migration access to/from Polley Lake re-established (i.e. after spring season), there is the potential for subsequent Rainbow Trout reproductive events to be inhibited, which could affect ongoing population viability and sustainability. Spawning Rainbow Trout looking to return to upper Hazeltine Creek to reproduce may seek out other nearby watercourses to undertake their reproductive cycle. Quinn (2005) suggested that if the conditions of a natal watercourse are sufficiently degraded, salmon(ids) may move elsewhere to spawn. However, the carrying capacity of other nearby watercourses may not entirely accommodate additional spawning recruits, native spawners may be displaced, or physical conditions in these other nearby watercourses may not be ideal due to homing imprinting (Quinn 2005). It is unknown whether any of these three conditions are actively ‘in play’ within Polley Lake, thus the magnitude of effect on the productivity (as a result of lost reproductive events) of Polley Lake Rainbow Trout cannot be reasonably estimated at this time.

Similarly, Rainbow Trout are the most abundant and widely distributed fish in lower Hazeltine Creek. Access to habitat in the lower reaches of Hazeltine Creek will offer opportunity for spring spawning Rainbow Trout to successfully migrate and reproduce to initiate the natural recruitment process. It is our understanding from MPMC (K. McMahon, pers. comm.) that rehabilitation efforts on Edney Creek have since re-opened migratory access between Edney Creek and Quesnel Lake providing the prospect for potential spring spawning Rainbow Trout. This may pose as an opportunity for spawning Rainbow Trout destined for Hazeltine Creek to complete their reproductive cycle. Furthermore, other species also utilized lower Hazeltine Creek, but in lower numbers suggesting lower Hazeltine Creek quite possibly did not offer preferred habitat conditions for these species.

5.2 Edney Creek

5.2.1 Quantification of Habitat Footprints

5.2.1.1 Aquatic Habitat

Edney Creek was assessed for habitat loss and mitigation options on September 19, 2014 after the TSF dam failure. There was evidence that when the tailings material in Hazeltine Creek reached the lower bridge, it flowed down the Horsefly-Likely FSR and into Edney Creek, reaching as far as approximately 55 m upstream of the Edney Creek bridge. The tailings reached as high as 1.5 m against the opposite bank (on the road side) of the creek.

Table 5-6 and Figure 5-2 (Appendix I) summarize the estimated aquatic footprint in lower Edney Creek as a result of the TSF dam failure. Mean channel (bankfull) width was obtained from previous site assessments on Edney Creek (Hallam Knight Piésold 1997).

In total, approximately 2,390 m^2 of aquatic habitat in Edney Creek was altered. Although fish distribution throughout the entire Edney Creek watershed (i.e., in the mainstem, tributaries, and associated lakes) is not completely known, based on data from previous habitat assessments (Hallam Knight Piésold 1996a; 1997) the total aquatic habitat area of the watershed has been estimated at 623,089 m^2. Thus, aquatic habitat affected by the TSF dam failure represents approximately 0.4% of the total aquatic habitat in the watershed. Further, the magnitude of physical alteration to lower Edney Creek is considered temporary given the small area and rehabilitation efforts to the watercourse that have been completed and recently commissioned.

Table 5-6: Estimated Aquatic Footprint of Edney Creek

Watercourse	Reach	Mean (Channel (Bankfull) Width (m)[1]	Affected Channel Length (m)	Affected Aquatic Area (m^2)
Edney Creek	-	6.0	398	2,390

[1] data from Hallam Knight Piésold (1997) (Site F1 at Edney Creek bridge).

5.2.1.2 Riparian Habitat

The total riparian area footprint of Edney Creek from its confluence with Hazeltine Creek to the upstream extent of tailings was estimated to be 20,215 m^2.

Table 5-7 and Figure 5-2 (Appendix I) provide a summary of the total riparian footprint that was altered on Edney Creek as a result of the TSF dam failure. Mean channel (bankfull) width was estimated from a site assessment conducted on Edney Creek in 1997 (Hallam Knight Piésold 1997).

Table 5-7: Estimated Affected Riparian Habitat of Edney Creek

Watercourse	Reach	Mean Channel (Bankfull) Width (m)[1]	Riparian Management Area (m)[2]	Affected Channel Length (m)	Affected Riparian Area (m^2)[3]
Edney Creek	-	6.0	40	398	20,215

[1] data from Hallam Knight Piésold (1997); (Site F1 at Edney Creek bridge).
[2] from edge of channel.
[3] includes affected riparian area on both sides of Edney Creek.

5.2.2 Potential Effects on Fish Productivity

Although Edney Creek contains a relatively diverse fish assemblage, historical fish relative abundance data were not available. As such, estimated loss of fish productivity due to the TSF dam failure could not be calculated.

5.2.2.1 *Species and Life Stages Potentially Affected*

5.2.2.1.1 Rainbow Trout

Rainbow Trout aging data from historical fisheries assessments (Hallam Knight Piésold 1997; Minnow Environmental 2009) indicate that adult Rainbow Trout are only present in Edney Creek during the spawning window (e.g., April/May). As such, it is assumed that adults were likely not present in Edney Creek during the TSF dam failure, and given the short segment of lower Edney Creek that was affected, it is likely only small proportion of adults would have been displaced if present. Fisheries assessments have also indicated that juvenile Rainbow Trout will remain in Edney Creek for up to three years. Thus, it is expected that some YOY and/or juvenile life stages of Rainbow Trout were likely displaced by the TSF dam failure. It is also believed that the effects to Rainbow Trout eggs were likely negligible, as eggs typically hatch in late June/early July (MPMC 2004) and hatching would have occurred in 2014 prior to the TSF dam failure.

5.2.2.1.2 Salmon Species

Although Chinook, Coho, and Sockeye Salmon have historically been captured or observed in Edney Creek, abundance numbers have been low. As such, effects to the recruitment of these species from Edney Creek to Quesnel Lake is likely negligible.

Adult Chinook return to their natal streams in the Quesnel Lake watershed as early as late July with the peak occurring in August (McPhail 2007). The likelihood of adults present in Edney Creek during the TSF dam failure is low considering the run timing of the species. The displacement to juvenile Chinook Salmon, however, is unknown but believed to be small due to the low historical escapement numbers of Chinook in Edney Creek.

Coho adults have been observed in Edney Creek in fall and due to their spawning time, were likely not present during the TSF dam failure. The displacement of juvenile Coho Salmon, however, is unknown but believed to be small due to the low historical escapement numbers observed in Edney Creek.

Sockeye Salmon/Kokanee have been documented in Edney Creek and typically spawn in September/October. The spawning time of the species is considerably later than when the TSF dam failure occurred suggesting that adults were likely not present in Edney Creek during the TSF dam failure. Potential displacement of juvenile Sockeye/Kokanee is also believed to be negligible given that fry migrate to their nursery lake shortly after emerging from the gravels.

5.2.2.1.3 Other Fish Species

Other fish species present in Edney Creek (e.g., Redside Shiner, Longnose Dace) would likely have had certain life stages displaced by the TSF dam failure, as some life history requirements are fulfilled in the stream environment.

5.2.2.2 Potential Long-Term Implications

Provided below is a summary of productivity components that were estimated to be altered/affected/interrupted as a result of the TSF dam failure (Table 5-8). Although the long-term implications of these outcomes cannot be confirmed, given the small area affected (4% of total watershed), it is believed that the long-term implications to overall productivity in Edney Creek will be relatively low.

Table 5-8: Productivity Components and Mechanisms for Reduced Productivity in Edney Creek

Productivity Component	Mechanism for Reduced Productivity
Production	Loss of production (e.g., habitat, fish abundance, diversity)
Growth	Physiochemical water properties considered in Golder (2015)
Individual performance	Physiochemical water properties considered in Golder (2015)
Survival	Direct mortalities Physiochemical water properties considered in Golder (2015)
Migration	Loss of access to key habitats
Reproduction	Loss of spawning events

The amount of habitat in Edney Creek affected by the TSF dam failure was small in comparison to that available in the Edney system, so obstruction to upstream migration and potential loss of reproductive events of Rainbow Trout appear to present the primary concern to Rainbow Trout population sustainability. It is our understanding that connectivity between Edney Creek and Quesnel Lake was restored prior to spring spawning (K. McMahen, pers. comm.). If so the case, then the risk to potential loss of reproductive events may be reduced. Although there is limited evidence of other fish species utilizing Edney Creek, restoring access may also contribute to the productivity of other species (i.e., Coho Salmon) looking to utilize or migrate out from Edney Creek.

5.3 Quesnel River

No permanent physical alteration of habitat is believed to have occurred in the Quesnel River. The potential for water quality-related effects are addressed in the Quesnel and Polley Lakes Impact Assessment (Golder 2015). The potential for settling of suspended particles is its outlet addressed by Minnow Environmental through the use of sediment traps (Minnow Environmental 2015).

5.4 Quesnel Lake

The objective of this section of the FFHIA is to discuss the potential effects of the TSF dam failure and to estimate the alteration to physical components of habitat and potential effects on the productivity of fish found in the West Arm of Quesnel Lake.

5.4.1 Fish Groups

Table 5-9 below summarizes the fish species groups identified for Quesnel Lake and their association with commercial, recreational and Aboriginal fisheries.

Table 5-9: Summary of Each Species Group indicating whether part of a commercial, recreational or Aboriginal fishery

Fish Group	Quesnel Lake Fish Species	Commercially Fished	Recreationally Fished	Aboriginal Fish
Migratory salmonids	Sockeye Salmon	X	X	X
	Coho Salmon*	X	X	X
	Chinook Salmon	X	X	X
Resident salmonids	Kokanee		X	X
	Rainbow Trout		X	X
	Bull Trout+		X	X
	Lake Trout		X	X
	Mountain Whitefish		X	X
	Pygmy Whitefish		X	X
	Lake Whitefish		X	X
Benthic species	Burbot		X	X

*Endangered (COSEWIC)
+Species of special concern (COSEWIC)

Other pelagic non salmonid and non fishery species that may occur in the West Arm include: Longonse Sucker, Largescale Sucker, Slimy Sculpin, Redside Shiner, Longnose Dace, Leopard Dace, Northern Pikeminnow, Peamouth Chub, and Lake Chub.

5.4.1.1 Littoral Zone

The littoral zone of Quesnel Lake is defined by the likely maximum growing depth of the dominant native aquatic plants in the West Arm of Quesnel Lake, namely *Potamageton* spp (Ecoscape 2012).

5.4.1.1.1 Littoral Zone Fish Assemblage

About 20 species of fish inhabit the littoral zone of Quesnel Lake and include species groupings such as migratory salmonids, resident salmonids, benthic species, and pelagic, non-salmonid species (Table 5-10). Migratory salmonids will typically use the littoral zone as rearing and foraging habitat during the YOY and juvenile life history stage. Unlike the migratory salmonids documented in Quesnel Lake, resident salmonids rely on littoral habitat for rearing (YOY and juvenile), foraging (juvenile and adult) and spawning (with the exception of Bull Trout)(Bryant et al. 1996, Hatfield 1996, McPhail 2007). The remaining species groupings consisting of benthic and potential pelagic, non-salmonid species will utilize the littoral zone for rearing (YOY and juvenile), foraging (juvenile and adult) and spawning (adult).

Table 5-10: Life History Stages of Fish Species Inhabiting Quesnel Lake Littoral Zone

Species Grouping	Species	YOY	Juvenile	Adult
Migratory Salmonids	Sockeye Salmon	Rearing	Rearing, Foraging	Spawning
	Coho Salmon	Rearing	Rearing, Foraging	
	Chinook Salmon	Rearing	Rearing, Foraging	
Resident Salmonids	Bull Trout		Rearing, Foraging	Foraging
	Rainbow Trout	Rearing	Rearing, Foraging	Spawning, Foraging
	Kokanee	Rearing	Rearing, Foraging	Spawning, Foraging
	Lake Trout	Rearing	Rearing, Foraging	Spawning, Foraging
	Mountain Whitefish	Rearing	Rearing, Foraging	Spawning, Foraging
	Pygmy Whitefish	Rearing	Rearing, Foraging	Spawning, Foraging
	Lake Whitefish	Rearing	Rearing, Foraging	Spawning, Foraging
Benthic Species	Burbot	Rearing	Rearing, Foraging	Spawning, Foraging
	Largescale Sucker	Rearing	Rearing, Foraging	Spawning, Foraging
	Longnose Sucker	Rearing	Rearing, Foraging	Spawning, Foraging
	Slimy Sculpin	Rearing	Rearing, Foraging	Spawning, Foraging
Pelagic, Non-Salmonid Species	Redside Shiner	Rearing	Rearing, Foraging	Spawning, Foraging
	Longnose Dace	Rearing	Rearing, Foraging	Spawning, Foraging
	Leopard Dace	Rearing	Rearing, Foraging	Spawning, Foraging
	Northern Pikeminnow	Rearing	Rearing, Foraging	Spawning, Foraging
	Peamouth Chub	Rearing	Rearing, Foraging	Spawning, Foraging
	Lake Chub	Rearing	Rearing, Foraging	Spawning, Foraging

5.4.1.1.2 Alterations to Physical Habitat Properties in Littoral Zone

The littoral zone surrounding the Hazeltine Creek mouth was scoured and/or buried as a result of the TSF dam failure (SNC-Lavalin 2015b). *Potamogeton* was identified as the most common and abundant aquatic plant in the littoral zone of the West Arm of Quesnel Lake (Ecoscape 2012). The extent of littoral habitat altered was defined by the length of littoral zone adjacent to identified regions of tailing deposits at the terminus of Hazeltine Creek. This extent was defined by the Hazeltine Creek Hydrotechnical and Geomorphological Impact Assessment (SNC-Lavalin 2015b) (Figure 5-1).

Fiiigure 5-1: Tailings extent and extent of affected littoral zone

The length of shoreline in the West Arm (October 2001) is estimated at 35,330 m and the length of shoreline affected by the TSF dam failure is estimated at 2,081 m.

The total littoral area (0-6m) of the West Arm (October 2001) was estimated to be 1,458,051 m^2 and the littoral area affected by the TSF dam failure is estimated at 94,394 m^2 or 6.5% of the total West Arm littoral zone (Figure 5-4).

Fivgure 5-4: Littoral area in the West Arm of Quesnel Lake and affected area

5.4.1.1.3 Quality of Lost Littoral Zone Habitat

The importance of the littoral zone adjacent of Hazeltine Creek to the productivity of fish is described in Ecoscape (2012). The authors undertook FIM of about 70 km of shoreline in the West Arm of Quesnel Lake. The study area included the portion of the West Arm of the lake, into which Hazeltine Creek drains, with the easternmost boundary of the study area located approximately 2 km west of the mouth of Whiffle Creek.

Using the inventory data, field reviews and other data sources the authors also developed an aquatic habitat index (AHI) to characterize and rank the estimated value and sensitivity of different shorelines of the West Arm. The AHI is used to analyze the habitat value of a shoreline segment relative to those from different parts of the lake or different lakes. Three categories are used to derive AHI scores: biophysical (e.g., shoretype, substrate), fisheries (e.g., juvenile rearing suitability) and shoreline vegetation.

Results of the foreshore mapping completed by Ecoscape (2012) indicate that:

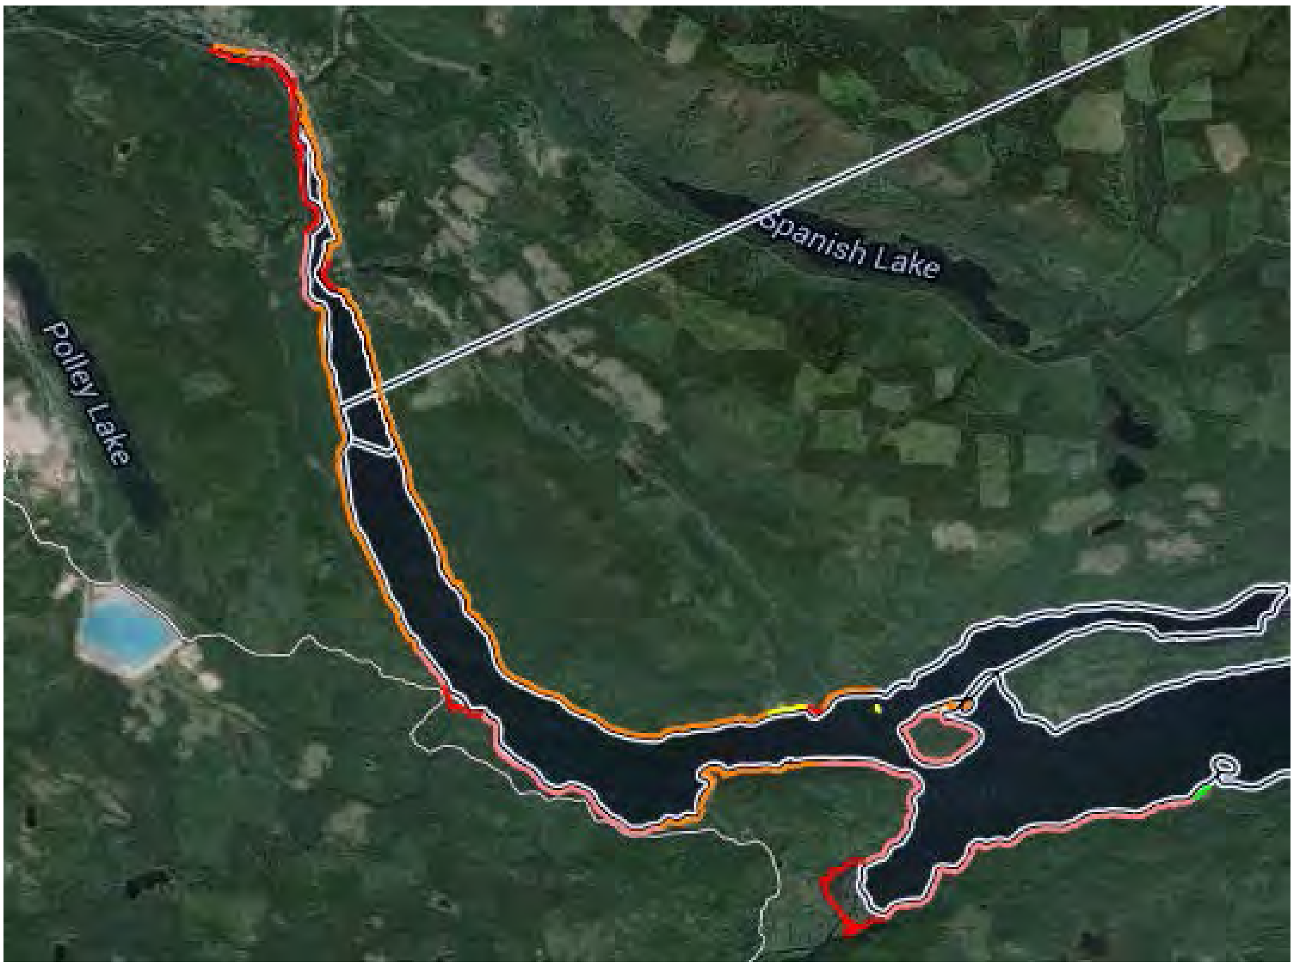
- The most predominant shore types observed around the West Arm of Quesnel Lake were gravel beach, accounting for 49% (or 34 km) of the study area, and rocky shore, accounting for over 35% (or 24.2 km).
- 36% (25 km) of shoreline in the study area had aquatic vegetation, predominantly emergent vegetation (including grasses and herbaceous vegetation) located below the high water level.
- Approximately 77% (54 km) of the shoreline in the study area showed low level (less than 10%) impact from shoreline modification (e.g., retaining walls, roads).
- High juvenile rearing value was identified to occur along 14 km of the shoreline in the study area, with land use disturbance noted along 2% (322 m). Note that at the time of this assessment, maps showing the location of high juvenile habitat rearing value along the shoreline of the West Arm were not obtained or available, but it was estimated that 14 of 70 km or 20% of the shoreline was high value.

Results of the aquatic habitat inventory completed by Ecoscape (2012) indicated that:

- Approximately 51% of the shoreline is ranked as ‘Very High’ and ‘High’ value, 48% of the shoreline length is moderate value, and the remaining 2% is ranked ‘Low’ and ‘Very Low’ value.
- ‘Very High’ value shorelines occurred primarily adjacent to stream mouths and gravel shores, with a reduced representation of ‘Very High’ value habitat occurring along rocky, cliff/bluff and sand shores. The West Arm of Quesnel Lake exhibited limited ‘Very Low’ AHI ratings.

- Within those areas ranked as ‘Very High’, the shoreline was 96% natural in terms of land use; in ‘High’ value areas, the shoreline was 95% natural; and within ‘Moderate’ value areas the shoreline was 80% natural. Areas of ‘Low’ value were around 48% natural, while areas with ‘Very Low’ value areas had 5% of the shoreline remaining natural.
- Examination of the AHI rating maps (CMN 2015) indicated that the shoreline adjacent to the Hazeltine Creek mouth was considered to have a ‘Very High’ AHI (Figure 5-5 and Figure 5-6).

It is estimated form the CMN mapping data that approximately 15% of the ‘Very High’ rated juvenile habitat in the West Arm occurred at the mouth of Hazeltine Creek and was altered by the TSF event.



Fvgure 5-5: Locations in the west arm of Quesnel Lake with Moderate (orange), High (pink), or ‘Very High’ (red) AHI ratings (CMN 2015)

Fvigure 5-6: The mouth of Hazeltine Creek is rated as 'Very High' (red) AHI, with an approximate shoreline length of 1200 m (CMN 2015).

5.4.1.1.4 Littoral Zone Effect Assessment

An assessment of lost productivity of fish in the littoral zone during the event or after then event was not possible because no information was available describing the use of littoral zone habitats by fish.

5.4.1.2 Limnetic Zone

5.4.1.2.1 Limnetic Zone Fish Assemblage

Approximately 18 species of fish are expected to inhabit the limnetic zone (MOE Habitat wizard, Table 5-11). Similar to the littoral zone, four species groupings are present. Migratory salmonids utilize the limnetic zone for rearing and foraging until they undergo smoltification and migrate downstream towards the marine environment. Resident salmonids will also typically use the zone for rearing and foraging during various life history phases. Benthic species are usually only present in the limnetic zone for a short period of time after hatching and consequently rear in the pelagic column until settling on the lake bed (Bryant et al. 1996, Hatfield 1996, McPhail 2007). Adult Burbot, however, will also make vertical migrations to the open water column in search of food. The presence of pelagic, non-salmonid species in the limnetic zone are likely foraging.

Table 5-11: Life History Stages of Fish Species Inhabiting Quesnel Lake Limnetic Zone

Species Grouping	Species	YOY	Juvenile	Adult
Migratory Salmonids	Sockeye Salmon	Rearing	Rearing, Foraging	
	Coho Salmon		Rearing, Foraging	
	Chinook Salmon		Rearing, Foraging	
Resident Salmonids	Bull Trout		Rearing, Foraging	Foraging
	Rainbow Trout		Rearing, Foraging	Foraging
	Kokanee	Rearing	Rearing, Foraging	Foraging
	Lake Trout	Rearing	Rearing, Foraging	Foraging
	Mountain Whitefish	Rearing	Rearing, Foraging	Foraging
	Pygmy Whitefish	Rearing	Rearing, Foraging	Foraging
	Lake Whitefish	Rearing	Rearing, Foraging	Foraging
Benthic Species	Burbot	Rearing		Foraging
	Largescale Sucker	Rearing		
	Longnose Sucker	Rearing		
Potential Pelagic, Non-Salmonid Species	Redside Shiner			Foraging
	Longnose Dace			Foraging
	Northern Pikeminnow			Foraging
	Peamouth Chub			Foraging
	Lake Chub			Foraging

5.4.1.2.2 Limnetic Zone Effect Assessment

No physical alteration of habitat occurred in the limnetic zone of Quesnel Lake. The potential for physiochemical related effects (e.g., turbidity, water temperature) are addressed in the Golder (Golder Associates Ltd.). 2015a. Mount Polley Tailings Dam Failure – Surface Water Quality Impact Assessment.

5.4.1.3 Profundal Zone

5.4.1.3.1 Profundal Zone Fish Assemblage

The profundal zone of Quesnel Lake is likely used by seven fish species and three species groups, namely migratory and resident salmonids, and benthic species (MOE Habitat wizard, Bryant et al. 1996, Hatfield 1996, McPhail 2007; Table 5-12). Of the migratory species, only Sockeye Salmon (YOY and juvenile) are likely rearing and feeding in the upper profundal zone as demonstrated by historical DFO hydroacoustic surveys (e.g., Morton and Williams 1990); the young salmon were apparently avoiding warm (greater than 17°C) waters above the thermocline. The resident salmonid grouping consists of Bull Trout, Kokanee, Lake Trout, Pygmy Whitefish, and Lake Whitefish. Bull Trout and Lake Trout are only typically present during the adult stage as they forage the depths for prey. Both species of whitefish and Kokanee will utilize the profundal zone for rearing and foraging opportunities (Bryant et al. 1996, Hatfield 1996, McPhail 2007).

Table 5-12: Life History Stages of Fish Species Inhabiting Quesnel Lake Profundal Zone

Species Grouping	Species	YOY	Juvenile	Adult
Migratory Salmonids	Sockeye Salmon	Rearing	Rearing, Foraging	
Resident Salmonids	Kokanee	Rearing	Rearing, Foraging	Foraging
	Bull Trout			Foraging
	Lake Trout			Foraging
	Pygmy Whitefish		Rearing, Foraging	Foraging
	Lake Whitefish		Rearing, Foraging	Foraging
Benthic Species	Burbot			Foraging

5.4.1.3.2 Profundal Zone Effect Assessment

No physical alteration of habitat likely occurred in the profundal zone of Quesnel Lake. The potential for physiochemical related effects (e.g., turbidity, water temperature) are addressed in the Golder (Golder Associates Ltd.). 2015a. Mount Polley Tailings Dam Failure – Surface Water Quality Impact Assessment.

5.4.1.4 Benthic Zone

5.4.1.4.1 Benthic Zone Fish Assemblage

The benthic zone fish assemblage includes species that associate with the lake bed in order to fulfill any of their life history requirements (Table 5-13). Resident salmonids (both juvenile and adult stage) will use the benthic zone to rear and forage (juveniles), while adults will rely on the lake bed for food as well as potential spawning habitat. All benthic species and respective life history stages will utilize the lake bed for rearing (YOY, juveniles), foraging (juvenile, adult) and spawning (adult). For the three potential pelagic, non-salmonid fish species, both the juvenile and adult phases may be present on the lake bed for rearing, foraging and spawning.

Table 5-13: Life History Stages of Fish Species Inhabiting Quesnel Lake Benthic Zone

Species Grouping	Species	YOY	Juvenile	Adult
Resident Salmonids	Rainbow Trout		Rearing, Foraging	Spawning, Foraging
	Bull Trout		Rearing, Foraging	Spawning, Foraging
	Lake Trout		Rearing, Foraging	Spawning, Foraging
	Mountain Whitefish		Rearing, Foraging	Spawning, Foraging
	Pygmy Whitefish		Rearing, Foraging	Spawning, Foraging
	Lake Whitefish		Rearing, Foraging	Spawning, Foraging
Benthic Species	Burbot	Rearing	Rearing, Foraging	Spawning, Foraging
	Largescale Sucker	Rearing	Rearing, Foraging	Spawning, Foraging
	Longnose Sucker	Rearing	Rearing, Foraging	Spawning, Foraging
	Slimy Sculpin	Rearing	Rearing, Foraging	Spawning, Foraging
Potential Pelagic, Non-Salmonid Species	Northern Pikeminnow		Rearing, Foraging	Foraging
	Peamouth Chub		Rearing, Foraging	Spawning, Foraging
	Lake Chub		Rearing Foraging	Foraging

5.4.1.4.2 Benthic Zone Physical Habitat Properties

Tetra Tech (2015; Bathymetry Analysis and Volume Balance) determined that the surface area of lake-bed below the 100-m depth contour covered after the event was about 1.81 km^2. Lake bed benthic habitats that were covered would result in loss of any productive habitat values to benthic fish species such as Burbot and Slimy Sculpin.

The potential for physiochemical related effects (e.g., turbidity, water temperature) are addressed in the Golder (Golder Associates Ltd.). 2015a. Mount Polley Tailings Dam Failure – Surface Water Quality Impact Assessment.

5.4.2 Quesnel Lake Assessment Summary

Table 5-14 summarizes the potential effects of the TSF dam failure on physical alterations to Quesnel Lake fish habitat in four major lake zones.

Table 5-14: Summary of Physical Alterations to Fish Habitat in Quesnel Lake

Lake Zone	Estimated amount of lake zone habitat physically altered
Littoral	2,081 m of lake shoreline permanently altered 94, 394 m2 of littoral zone permanently altered 15% of very high rated juvenile fish habitat at the mouth of Hazeltine Creek permanently altered
Limnetic	No physical habitat properties altered; physiochemical water properties considered in Golder (2015).
Profundal	No physical habitat properties altered; physiochemical water properties considered in Golder (2015).
Benthic (lakebed)	Permanent alteration to physical habitat of the West Arm lakebed below the 100 m contour is estimated at 1.8 km^2 Tetra Tech (2015).

5.5 Polley Lake

5.5.1 Fish Impact Assessment

Tailings from the TSF dam failure entered Polley Lake at the lake outlet to Hazeltine Creek; however, there are no current estimates of how much linear shoreline or surface area of lake bed was physically altered by the event.

The TSF dam failure resulted in blockage of the upper Hazeltine Creek and hence the Polley Lake Rainbow Trout population lost access to creek spawning habitat for one season. One cohort of production was lost. A reduction in rainbow trout returning to Polley Lake is likely to affect both the density and growth rates of fish in the lake. This in turn may affect future angling results (Lirette 2015).

The TSF dam failure may have impacted habitats important to Redside Shiner and Longonse Sucker in Polley Lake. However, there is currently insufficient scientific evidence confirming the habitats or population properties of these species in Polley Lake.

6 RECOMMENDATIONS FOR ADDITIONAL WORK

The duration and severity of the impacts as a result of the TSF dam failure on fish production and habitat will depend on the nature and success of the rehabilitation (i.e., offsetting) efforts to altered riverine and lacustrine habitats as well as monitoring the affected creek and lake systems for potential long-term (chronic) effects. The characterization of effects should be reassessed once rehabilitation efforts in the immediately affected areas are complete, and should continue to be re-examined in the context of the results of any effectiveness and biotic-response monitoring.

7 SUMMARY OF FINDINGS

The following is a summary of the key findings generated from the FFHIA.

Hazeltine Creek

The quantity of aquatic and riparian habitat permanently physically altered as a result of the TSF dam failure was estimated and is summarized in Table 7-1.

Table 7-1: Summary of Physical Alterations to Fish Habitat in Hazeltine Creek

Physical Habitat Type	Estimated Amount of Habitat Physically Altered
Aquatic	62,616 m^2 of aquatic habitat was permanently altered.
Riparian	717,249 m^2 of riparian habitat was permanently altered.

There is the potential for subsequent Rainbow Trout reproductive events to be inhibited, which could affect ongoing population viability and productivity. Spawning Rainbow Trout looking to return to upper Hazeltine Creek to reproduce may seek out other nearby watercourses to undertake their reproductive cycle, but it is unknown whether sufficient quantities and quality of spawning habitat exists to accommodate any Hazeltine Rainbow Trout. Rainbow Trout are the most abundant and widely distributed in lower Hazeltine Creek. Providing access to habitat in the lower reaches of Hazeltine Creek will offer opportunity for spring spawning Rainbow Trout to successfully migrate and reproduce to initiate the natural recruitment process. Other fish species also utilize lower Hazeltine Creek, but in lower numbers suggesting lower Hazeltine Creek quite possibly did not offer preferred habitat conditions. It is our understanding from MPMC (K. McMahen, pers. comm.) that rehabilitation efforts and connectivity with Quesnel Lake were commissioned prior to spring, thus it is possible that any spawning Rainbow Trout naturally destined for lower Hazeltine Creek may now access and utilize Edney Creek to complete their reproductive cycle. Monitoring of adult Rainbow Trout accessing the rehabilitated channel during the spring spawning window will confirm some degree of the channel's effectiveness.

Edney Creek

The quantity of aquatic and riparian habitat temporarily physically altered as a result of the TSF dam failure was estimated and is summarized in Table 7-2.

Table 7-2: Summary of Physical Alterations to Fish Habitat in Edney Creek

Physical Habitat Type	Estimated Amount of Habitat Physically Altered
Aquatic	2,390 m^2 of aquatic habitat was temporarily altered.
Riparian	20,215 m^2 of riparian habitat was temporarily altered.

The amount of habitat in Edney Creek altered by the TSF dam failure was small in comparison to that available in the Edney watershed, thus the obstruction to upstream migration and potential loss of reproductive events of Rainbow Trout appear to present the primary concern to Rainbow Trout population productivity. Although there is limited evidence of other fish species utilizing Edney Creek, restoring access may also contribute to the productivity of other species (i.e., Coho Salmon) looking to utilize or migrate out from Edney Creek. It is our understanding from MPMC (K. McMahen, pers. comm.) that rehabilitation of Edney Creek and its connectivity to Quesnel Lake was commissioned prior to this past spring (2015) with the aim to allow for unfettered upstream/downstream access (migration) for fish. Monitoring of adult Rainbow Trout accessing the rehabilitated channel during the spring spawning window will confirm some degree of the channel's effectiveness.

Quesnel River

No physical alteration of habitat is believed to have occurred in the Quesnel River. The potential for water quality-related effects are addressed in the Quesnel and Polley Lakes Impact Assessment (Golder 2015). The potential for settling of suspended particles is addressed by Minnow Environmental through the use of sediment traps (Minnow Environmental 2015).

Quesnel Lake

It was determined that the TSF dam failure impacted a 2,081 m length of West Basin shoreline at the mouth of Hazeltine Creek (about 6% of the total shoreline in the West Basin). The littoral area (0-6 m) affected by the TSF dam failure was estimated to be 94,394 m^2 or 6.5% of the total West Arm littoral zone. The amount of West Arm lakebed below 100 m depth impacted by the TSF dam failure was estimated by Tetra Tech (2015) to be about 1.8km^2. The summary of physical alterations of fish habitat as a result of the TSF dam failure was estimated and is summarized in Table 7-3.

Table 7-3: Summary of Physical Alterations to Fish Habitat in Quesnel Lake

Lake Zone	Estimated Amount of Lake Zone Habitat Physically Altered
Littoral	2,081 m of lake shoreline was permanently altered. 94,394 m^2 of littoral zone was permanently altered. 15% of very high rated juvenile fish habitat at the mouth of Hazeltine Creek was permanently altered.
Limnetic	No physical habitat properties altered; physiochemical water properties are being considered in Golder (2015a,b).
Profundal	No physical habitat properties were altered; physiochemical water properties are being considered in Golder (2015a,b).
Benthic (lakebed)	Permanent alteration to physical habitat of the West Arm lakebed below the 100 m contour is estimated at 1.8 km^2 Tetra Tech (2015).

Polley Lake

The TSF dam failure resulted in blockage of upper Hazeltine Creek and hence the Polley Lake Rainbow Trout population lost access to creek spawning habitat for one season. A reduction in rainbow trout returning to Polley Lake may affect future angling results.

The TSF dam failure may have impacted habitats important to Redside Shiner and Longonse Sucker in Polley Lake. However, there is currently insufficient scientific evidence confirming the habitats or population properties of these species in Polley Lake.

8 UNCERTAINTY ASSESSMENT

The FFHIA included the compilation and assessment of available fish and fish habitat data to evaluate for potential effects of the TSF dam failure on the species productivity in the main ecological units identified in the WQIA (Golder 2015). Table 8-1 lists some of the key uncertainties professionally determined by SNC Lavalin in the FFHIA data for each ecological unit that need to be understood to better understand the effects of the TSF dam failure on fish productivity.

Table 8-1: Summary of Key FFHIA Data Uncertainties for Each Ecological Unit to Better Understand the Effects of the TSF Dam Failure on Fish Productivity

Ecological Unit	Source of Uncertainty	Degree of Uncertainty	Comment
Polley Lake and upper Hazeltine Creek	• Pre and post fish population estimates and distribution within the littoral and limnetic zone of Polley Lake. • Pre and post event fish benthic habitat in Polley Lake. • Upper Hazeltine Creek fish population and production estimates with emphasis on Rainbow Trout.	• High • High • Moderate	Rainbow Trout in upper Hazeltine Creek is an important contributing population/stock to overall Rainbow Trout recreational fishery in Polley Lake (Lirette 2015).
Lower Hazeltine Creek	• Fish population and production rate estimates with emphasis on Rainbow Trout.	• Moderate	Historically, Rainbow Trout is the most abundant species observed. Production rates unable to be calculated with existing baseline data.
Edney Creek	• Post event fish population and production estimates with emphasis on Rainbow Trout.	• Low	Small proportion of Edney Creek was affected by the TSF dam failure, but number of fish utilizing lower Edney Cr at time of TSF dam failure is unknown.
Quesnel Lake Littoral Zone	• Fish species and densities present in the littoral zone at time of event.	• High	Future monitoring will be required to document fish use of the littoral zone.
Quesnel Lake Limnetic Zone	• Horizontal and vertical distribution of juvenile salmon and other pelagic species post event.	• Moderate	Monitoring of juvenile salmon vertical and horizontal distribution in the limnetic zone will reduce uncertainty.
Quesnel Lake Benthic Zone	• Pre and post event fish species and densities present on lake bed and habitats covered by the debris flow from Hazeltine Creek.	• High	Monitoring will reduce the uncertainty of re-colonization of benthic lake habitats and benthic species.

11 NOTICE TO READER

This report has been prepared and the work referred to in this report have been undertaken by SNC-Lavalin Inc. (SNC-Lavalin) for the exclusive use of Mount Polley Mining Corporation, who has been party to the development of the scope of work and understands its limitations. The methodology, findings, conclusions and recommendations in this report are based solely upon the scope of work and subject to the time and budgetary considerations described in the proposal and/or contract pursuant to which this report was issued. Any use, reliance on, or decision made by a third party based on this report is the sole responsibility of such third party. SNC-Lavalin accepts no liability or responsibility for any damages that may be suffered or incurred by any third party as a result of the use of, reliance on, or any decision made based on this report.

The findings, conclusions and recommendations in this report (i) have been developed in a manner consistent with the level of skill normally exercised by professionals currently practicing under similar conditions in the area, and (ii) reflect SNC-Lavalin's best judgment based on information available at the time of preparation of this report. No other warranties, either expressed or implied, are made as to the professional services provided under the terms of our original contract and included in this report. The findings and conclusions contained in this report are valid only as of the date of this report and may be based, in part, upon information provided by others. If any of the information is inaccurate, new information is discovered, site conditions change or applicable standards are amended, modifications to this report may be necessary. This report must be read as a whole, as sections taken out of context may be misleading. If discrepancies occur between the preliminary (draft) and final version of this report, it is the final version that takes precedence. Nothing in this report is intended to constitute or provide a legal opinion.

The contents of this report are confidential and proprietary. Other than by Mount Polley Mining Corporation, copying or distribution of this report or use of or reliance on the information contained herein, in whole or in part, is not permitted without the express written permission of Mount Polley Mining Corporation.

APPENDIX II

Hazeltine and Edney Creeks Fish Life History Summaries

HAZELTINE, BOOTJACK AND EDNEY CREEKS FISH LIFE HISTORY SUMMARIES

This document provides a summary the life histories of impacted fish (as defined under the *Fisheries Act*) that were known to have been displaced, presented in their general order of sampled abundance.

Burbot *(Lota lota)*

The burbot is the only member of the Gadidae (cods) family that inhabits the freshwaters of British Columbia (BC). This fish usually spends its time on the bottom in the deep, cool areas of lakes and rivers (BC Ministry of Environment [MoE] 2015). Lacustrine, adfluvial and fluvial populations can occur in the same river systems (McPhail 1997).

Spawning

The age at maturity varies between systems and life histories but they typically mature between 2 to 8 years (Roberge et al. 2002). McPhail (1997) noted the age at first maturity varies by latitude and males usually reach sexual maturity a year or two before females.

Burbot spawn at night in mid-winter under the ice, typically from January through March (BC MoE 2015), but spawning has been recorded to range between November and May (Roberge et al. 2002). Spawning occurs in lakes (over shallows) and in rivers (side channels behind deposition bars) at temperatures ranging from 0° to 4°C (McPhail 1997; Roberge et al. 2002; BC MoE 2015).

Burbot aggregate and up to 12 adult burbot spawn together in a ball approximately 60 cm in diameter which moves over the bottom shedding milt and eggs (BC MoE 2015; McPhail 1997). Female burbot have very high fecundity with average individual egg release of over 900,000 eggs in some populations though not all adult burbot spawn every year (McPhail 1997). Eggs are released into the water column, and sink slowly to the substrates below (Scott and Crossman 1973; Roberge et al. 2002). Spawning in lakes occurs over fine to gravel substrates in shallow bays, or shoals, typically in shallow water up to 1.25 m deep, but can range to 10 m depth (BC MoE 2015; Roberge et al. 2002; McPhail 1997). In rivers they spawn over clean sand, gravel or cobble and rubble substrate (McPhail 1997).

The eggs hatch after about 30 days, with a larval stage occurring before growing into fry (BC MoE 2015).

Rearing

Larvae are pelagic in lakes appearing shortly after ice-out forming small schools and drifting passively for about a month, or in rivers getting swept downstream as drift (McPhail 1997). The mortality in the larval stage is high. During the larval drifting and schooling period, burbot feed on rotifers, copepods, and cladocerans (McPhail 1997). By early summer, at a size range of 15 mm to 50 mm, larvae shift to a primarily benthic form and take up a demersal life (McPhail 1997). This habitat shift is accompanied by a transition from crepuscular to nocturnal activity, and a change in diet. Young of the year burbot (YOY) feed on larger items such as amphipods, insects, etc. until they are large enough to forage on fish (McPhail and Paragamian 2000, as cited in Roberge et al. 2002). Juvenile burbot remain inshore in relatively shallow water and feed and grow throughout the winter. In streams, young burbot associate with undercut banks, submerged logs and weeds preferably near rocky areas, but will use sandy areas (Roberge et al. 2002; BC MoE 2015). Juvenile burbot, up to 500 mm, are known to feed heavily on M*ysis relicta* (mysis shrimp) (Scott and Crossman 1973, cited by Roberge, 2002).

Subadult Burbot occupy similar habitat as YOY: shallow littoral environments with rocks, weeds or debris as cover (McPhail and Paragamian 2000 as cited in Roberge et al. 2002). With increased size burbot move to deeper water of lakes and recruit to the adult population at about the time of sexual maturity (McPhail 1997; Roberge *et al.* 2002). In lakes, burbot seek deeper cooler waters during the summer and adult burbot have been caught as deep as 210 m (BC MoE 2015). Burbot also inhabit cool, large rivers (Scott and Crossman 1973; Tallman 1996, cited by Roberge *et al.* 2002). Adult burbot forage almost exclusively on fish (Scott and Crossman, 1973; McPhail, 1997; Roberge *et al.* 2002). Adult burbot are nocturnal ambush predators, locating their prey first by smell, then by vibrations as the prey nears (BC MoE 2015).

Both subadults and adults are temperature sensitive and usually avoid temperatures above 12°C (McPhail, 1997). Above 12°C there is an avoidance response with burbot shifting their distribution to below the thermocline (e.g. Edsall et al. 1993; McPhail, 1997). If this is not possible, summer kills may occur (Lafferty et al. 1992, as cited in McPhail 1997).

In Canada, burbot live to a maximum age of approximately 22 years, dependant on water temperatures, with southern populations tending to have shorter lifespans (McPhail and Paragamian 2000, cited in Roberge et al. 2002).

Local Population

Burbot were the most common fish species captured in lower Hazeltine Creek, primarily in areas close to the confluence with Quesnel Lake. The age and population type (i.e., fluvial, lacustrine, adfluvial) of burbot captured in lower Hazeltine Creek was not confirmed during historical studies.

However, as adult burbot spawn in winter or early spring, capture results in lower Hazeltine Creek suggest that most (84%) were YOY (Minnow Environmental 2009), suggesting these are likely adfluvial fish from Quesnel Lake utilizing lower Hazeltine Creek for spawning.

The presence of beaver dams near the confluence with Quesnel Lake may pose an occasional upstream migration barrier to fish (Minnow Environmental 2007), but when passable, the pools associated with the beaver dams may have provided important nursery habitat characteristics in a stream smaller in size than typically identified for the species in the literature.

Rainbow Trout *(Oncorhynchus mykiss)* – Freshwater resident

Rainbow trout occupy many different habitat types over their range. Stream-dwelling rainbow trout are typically found in habitat with gravel substrate and riffle-pool morphology, while lake-resident rainbow trout are usually found in deeper, cool lakes with adequate shallows and vegetation for food production (BC MoE 2015). Lake dwelling rainbow trout are found in a variety of lake types, but are most commonly found in deep, cold oligotrophic lakes that have inlet and outlet streams with adequate spawning habitat (Ford et al. 1995, cited in Roberge et al. 2002). Water temperatures greater than 24°C are lethal to adult rainbow trout (Roberge et al. 2002).

Spawning

Rainbow trout typically spawn in flowing water; however, a few introduced populations spawn on gravel beaches in lakes (McPhail 2007).

Rainbow trout usually spawn for the first time in their third or fourth year. In the larger piscivorous fish, maturity is delayed (BC MoE 2015). If food and other factors are suitable, most mature individuals spawn every year.

In BC, freshwater resident Rainbow Trout spawning is triggered by rising water levels and water temperatures (above 5°C) and typically occurs from April to July (depending on latitude and altitude) (McPhail 2007). Spawning typically occurs at temperatures ranging from 8°C to 15°C (Scott and Crossman 1973, cited in Roberge et al. 2002).

Redds are built in clear, silt-free cold water near vegetated banks over fine gravel in riffles above pools (McPhail 2007), and in clean gravel in riffle habitat at the tail of pools (BC MoE 2015). Preferred small gravel substrate size ranges from 6mm to 52 mm (Whyte et al. 1997). Typical water velocities in spawning sites range from 0.3 m/s to 0.9 m/s and water depths range from 0.15 m to 2.5 m, with site selection dependent on body size (McPhail 2007; Whyte et al. 1997). As such, most, if not all, native, lake populations of rainbow trout migrate to associated lake tributaries to spawn (McPhail 2007).

Access to spawning areas in streams is limited by channel gradient, elevation drops (e.g. cascades or falls), water depths and velocities. Stream gradients in excess of 20% (BC MoF, 1998), water velocities exceeding adult burst swim speed of 4.3 m/s, jump heights over 1.5 m or jump height to plunge-pool depth ratios above 1:1.25 can all function as barriers to adult rainbow trout migration to spawning areas (Whyte et al. 1997). Bjornn and Reiser (1991) indicated maximum water velocities for prolonged swimming of 1.22 m/s (small fish) to 2.44 m/s (large fish), while Whyte et al. (1997) reported 1.8 m/s as an adult rainbow trout prolonged swim speed.

Rearing

Eggs hatch into alevins after four to seven weeks, depending on water temperature (BC MoE 2015). It takes three to seven days after hatching for the alevins to absorb the remaining yolk to become fry (BC MoE 2015). Free-swimming fry emerge from the gravel during the summer. The fry of lake-resident spawners may move into the lake immediately, or, when there is sufficient stream flow, they may spend up to three years in the stream to avoid lake predators (BC MoE 2015).

Juveniles remain inshore during winter and early spring (Beauchamp 1990b, as cited in McPhail 2007) and by day are associated with cover (cobble and boulders or woody debris) (McPhail 2007). At night, they leave cover and forage over sand and gravel substrates (Tabor and Wurtsbaugh 1991, as cited in McPhail 2007). Lake populations of Rainbow Trout fry typically migrate to their lake from rearing streams in late summer or early fall (McPhail 2007).

Adult rainbow trout from large lakes are primarily piscivores, and grow to a large size (Roberge et al. 2002). In streams, the average size of rainbow trout has been shown to vary depending on elevation, with size decreasing with increasing elevation (McMichael and Pearsons 1998 as cited in Roberge et al. 2002). Rainbow trout in streams primarily feed on crustaceans, molluscs, and insects such as caddis flies and black flies, but they also eat salmon eggs when available (BC MoE 2015).

Local Population

The Quesnel Lake rainbow trout population spawns primarily in the Horsefly and Mitchell Rivers which support rearing juveniles for at least one and possibly two winters (Tredger 1989; as cited in Sebastian et al. 2003).

Polley Lake contains a population of rainbow trout which were isolated from downstream populations due to documented migration barriers on Hazeltine Creek between Polley Lake and Quesnel Lake. No historical fish stocking has been recorded to have occurred in Polley Lake. Polley Lake is di-mictic, with well-developed thermal stratification in summer that occurs at approximately 5 m to 15 m (Minnow Environmental 2014). Although well-mixed in winter, water temperatures gradually increase with depth; dissolved oxygen levels gradually decrease with depth, which has been observed year-round. Levels of dissolved oxygen below the BC MoE water quality guidelines for the protection of aquatic life (i.e., < 5mg/L) have been observed at depths starting at 20 m year-round.

Rainbow Trout from Polley Lake likely migrate to upper Hazeltine Creek and into Bootjack Creek to spawn in the spring as a result of rising water temperatures (above 5ºC) and levels, typically after ice-out (mid-April to mid-May), with spawning occurring from early May to early June (MPMC 2004). Adults, along with juveniles from the previous spawning season, return to Polley Lake after freshet (mid-May to mid-June), with fry emerging from the gravel and beginning to actively feed in late June or early July in upper Hazeltine Creek and Bootjack Creek (MPMC 2004).

Young-of-the-year Rainbow Trout were almost exclusively captured in upper Hazeltine and Bootjack Creeks (over 98% of catch) during a fish and fish habitat assessment conducted in 1990, with the remainder comprised of one and two year olds (Bruce and Slaney 1991). This indicates the majority of Rainbow Trout fry present in Hazeltine and Bootjack Creeks migrate to Polley Lake within their first year after hatching (i.e., as young-of-the-year). This is further substantiated by scale analysis of adult rainbow trout present in the lake, which indicated that 80% were recruited to the lake as yearlings (Bruce and Slaney 1991).

Lower Hazeltine Creek from the mouth upstream to the confluence with Edney Creek, has been identified in the Horsefly Sustainable Resource Management Plan as critical habitat (BC Ministry of Forest, Lands, Natural Resource Operations [MFLNRO] 2005). Species considered in the plan included Salmon, Bull Trout, Rainbow Trout, and Kokanee; however, it did not specifically state which of these species the critical habitat in lower Hazeltine applied to (BC MFLNRO 2005).

Length-frequency analysis of the rainbow trout capture data from both upper and lower Hazeltine Creek from two separate studies (Minnow Environmental 2009; Bruce and Slaney 1991) indicated the almost exclusive presence of YOY fish, with few older fish present (likely juveniles). This suggests that adult rainbow trout migrate from Polley and Quesnel Lakes to spawn in the creek in the spring, returning to the lakes post-spawning.

Suitable spawning gravels for rainbow trout were not common within the section from the confluence with Quesnel Lake upstream approximately 525 m, as it was dominated by cobble and larger gravel mixes (Minnow Environmental 2009).

Edney Creek was observed to be ponded just upstream from the confluence with Hazeltine Creek due to a beaver dam (Minnow Environmental 2007). This ponded area likely provided overwintering habitat for fish in the creek. Fish aging data from historical fisheries assessments (Hallam Knight Piesold 1997; Minnow Environmental 2009) suggest that a subset of adults from Quesnel Lake likely migrate annually to Edney Creek to spawn in the spring, returning to the lake afterwards. The majority of their offspring (fry) spend up to three seasons in Edney Creek before migrating to Quesnel Lake to continue rearing.

The highest density of rainbow trout in the Edney Creek watershed was consistently observed in the upper section of the drainage at a site downstream of Edney Lake (F2) (Hallam Knight Piesold 1996a, 1997). Adult rainbow trout likely utilize Edney Lake for rearing and spawn in the creek itself, with juveniles utilizing the Edney Creek as rearing habitat (MPMC 2009).

Sockeye Salmon *(Oncorhynchus nerka)*

Sockeye salmon occur in two forms, the anadromous sockeye salmon and the freshwater lake-resident kokanee. The life cycle of juvenile sockeye salmon is different from other Pacific salmon in that they typically rear in lakes rather than streams, although some river mainstem rearing populations do occur (Woods et al. 1987 as cited in Roberge et al. 2002).

Spawning

Sockeye salmon age of maturity varies, but all sockeye return from the ocean to spawn by their maximum age of eight years, most typically after two to three years at sea (Burgner 1991, as cited in Roberge et al. 2002). In the Fraser River, migration to the spawning grounds begins in July and continues to late-August or early September (Gilhousen 1960, as cited in Roberge et al. 2002). Spawning occurs at temperatures ranging between 3 - 7°C (Scott and Crossman 1973, as cited in Roberge et al. 2002).

Sockeye salmon typically spawn in tributaries or outlets of lakes, and unlike the other Pacific salmon that tend to only spawn in fluvial habitats, they also spawn on littoral area beaches of lakes themselves (Whyte et al. 1997; Foerster 1968, as cited in Quinn 2005). Sockeye prefer spawning sites with sub-gravel flow, in shallow riffles, the outlet of lakes, or on beaches in lakes where there is upwelling (Parsons and Hubert 1988 as cited in McPhail 2007).

Female sockeye salmon select the redd site, and will defend the redd until near death (Burgner 1991, as cited in Roberge et al. 2002). Gravel diameters range from 10 mm to 25 mm, depending on water velocity and female size (McPhail 2007), but suitable substrate can range from 13 mm to 102 mm (Whyte et al. 1997). Preferred water depths range from 6 cm to 37 cm and water velocities range from 0.15 m/s to 0.85 m/s (McPhail 2007).

Access to spawning areas in streams can be limited by channel gradient, elevation drops (e.g., cascades or falls), water depths and velocities. Adult sockeye burst swim speed is 6.3 m/s (prolonged swim speed is 3.1 m/s) and maximum jump heights are 2.1 m with a jump height to plunge-pool depth ratios of 1:1.25 (Whyte et al. 1997).

Rearing

Juvenile sockeye salmon typically rear in lakes rather than streams, although some stream rearing populations do occur (Woods et al. 1987, as cited in Roberge et al. 2002). Most juvenile sockeye rear in lakes for the first year or two of their lives before migrating to sea (Quinn 2005; Whyte et al. 1997). However, three years of freshwater residency (Ricker 1941; Burgner 1991 as cited in Roberge et al. 2002) also occurs.

Sockeye YOY and older feed on plankton (Roberge et al. 2002). Vertical distribution of juvenile Sockeye Salmon can be quite variable within and among lakes throughout the year due to changes in water clarity and depth and the stability of the thermocline (Roberge et al. 2002). Diel vertical migration is thought to be a predatory response, so in turbid lakes, juvenile Sockeye Salmon may not undergo diel vertical migrations (Roberge et al. 2002).

Local Population

The lake is noted as being one of the largest sockeye salmon producing lakes in the Fraser River system (Nidle et al. 1994). Spawning adult salmon migrate up the Quesnel River into the west end of Quesnel Lake, with the majority of sockeye returning to Horsefly River and Mitchell River (Nidle et al. 1994; Hume et al. 2005) as well as Summit Creek (Hillaby 2011) and various small streams in the east arm or along the shores of the lake (Nidle et al. 1994; Hume et al. 2005). The majority of sockeye spawning in Quesnel Lake is east of Hazeltine Creek.

Past impacts have limited the Horsefly River to one dominant run of sockeye, which spawns on a four-year cycle and one subdominant run also on a four-year cycle. The Salmonid Enhancement Program of Department of Fisheries and Oceans (DFO) has a spawning channel on Horsefly River, with capacity for approximately 22,000 adult sockeye the channel was built in 1988-89 to enhance the sockeye salmon run in the sub-dominant years (Hillaby 2011). Recently hatched sockeye fry would be expected to migrate downstream to Quesnel Lake to rear immediately after emergence in the spring (McPhail 2007; MPMC, 1990).

Lower Hazeltine Creek from the mouth upstream to the confluence with Edney Creek, has been identified in the Horsefly Sustainable Resource Management Plan as critical habitat (BC MFLNRO 2005). Species considered in the plan included Salmon, Bull Trout, Rainbow Trout, and Kokanee; however, it did not specifically state which of these species the critical habitat in lower Hazeltine applied to (BC MFLNRO 2005).

Sockeye salmon spawner escapement data have been collected intermittently in Hazeltine Creek since 1989 (DFO 2014). Mean annual escapement over 15 sampling periods between 1989 and 2013 was 280 adult, summer-run sockeye, with a high of 1,616 observed in 1989 (DFO 2014). The escapement data suggest that sockeye primarily used Hazeltine Creek for spawning only during dominant years of their four year lifecycle (1989, 1993, 1997, 2001, 2005). However, while 2009 would have been considered a dominant year; no sockeye were enumerated, whereas 79 were documented in 2011. Recent data (from 2001, 2005 and 2011) suggested that more females were present in the creek than males (DFO 2014). No Kokanee have been captured or observed in lower Hazeltine Creek; however, they apparently use this section for spawning (Minnow Environmental 2007).

During a November 2007 salmon spawner assessment of the first 1000 m of Edney Creek upstream from the confluence with Hazeltine Creek, spawning habitat quality was considered high due to deep pools, abundant instream cover, and presence of spawning gravels (Cariboo Envirotech 2008). Rainbow Trout and sockeye salmon were the most abundant fish species captured in sampling of Edney Creek; however, sockeye were only captured in 1989. However, the presence of beaver dams near the confluence with Quesnel Lake may have prevented adult salmon from migrating upstream of this point in some years.

Chinook Salmon *(Oncorhynchus tshawytscha)*

There are two main forms of Chinook Salmon, stream-type and ocean-type, as well as many intermediates (Healey 1991, as cited in Roberge et al. 2002). Stream-type Chinook salmon spend a larger portion of their life within freshwater, both before migration to the ocean (one to three years) and during migration to spawning grounds (several months), and are more frequent in the northern range (above the 56th parallel). Ocean-type Chinook salmon spend less than a year rearing in freshwater and will enter freshwater only days or weeks before spawning, and are dominant in the southern range (below the 56th parallel) (Healey 1991, as cited in Roberge et al. 2002).

Spawning

Chinook salmon age of maturity varies, with two to three years spent at sea the most common, but all chinook return from the ocean to spawn by their maximum age of nine years (Roberge et al. 2002). In BC, migration timing to the spawning grounds is variable between stocks. Chinook salmon spawn in May or June in the most northern part of their range, between July to September in BC and as late as November or January in the most southern locations (Healey 1991, as cited in Roberge et al. 2002).

Chinook salmon typically inhabit large, low gradient (approximately 1%) river systems (Healey 1991, as cited in Roberge et al. 2002). Less commonly, Chinook can spawn on gravel shoals of lake shores or within small lake tributaries streams (Scott and Crossman 1973, as cited in Roberge et al. 2002).

Female Chinook salmon select the redd site. Redds are built in riffle-pool habitat on gravel and cobble substrates (Roberge et al. 2002). Gravel diameters range from 13 mm to 102 mm (Whyte et al. 1997).

Preferred water depths are a minimum 0.3 m and water velocities range from 0.32 m/s to 1.09 m/s (Whyte et al. 1997). Spawning has been recorded for depths up to 5 m (Roberge et al. 2002).

Access to spawning areas in streams can be limited by channel gradient, elevation drops (e.g., cascades or falls), water depths and velocities. Adult Chinook burst swim speed is 6.6 m/s (prolonged swim speed is 3.2 m/s) and maximum jump heights are 2.4 m with a jump height to plunge-pool depth ratios of 1:1.25 (Whyte et al. 1997).

Rearing

It is common for newly emergent ocean-type Chinook salmon young-of-the-year to migrate directly to the ocean where they remain in the estuary or nearshore areas for several months to reach smolt size before moving to the open ocean (Healey 1991, as cited in Roberge et al. 2002).

The YOY that remain in streams and rivers associate with cobble and boulder substrates, in fairly fast flowing water up to 1.0 m deep (Roberge et al. 2002). Preferred water temperature ranges between 12°C 14°C (Scott and Crossman 1973, as cited in Roberge et al. 2002). Chinook YOY feed on zooplankton and aquatic invertebrates in drift (Sommer et al. 2001, as cited in Roberge et al. 2002), juveniles feed on invertebrates and adults feed on fish (Scott and Crossman 1973, as cited in Roberge et al. 2002).

Local Population

Lower Hazeltine Creek from the mouth upstream to the confluence with Edney Creek, has been identified in the Horsefly Sustainable Resource Management Plan as critical habitat (BC MFLNRO 2005). Species considered in the plan included Salmon, Bull Trout, Rainbow Trout, and Kokanee; however, it did not specifically state which of these species the critical habitat in lower Hazeltine applied to (BC MFLNRO 2005).

There was no spawner escapement data for Chinook or Coho Salmon (DFO 2014). Chinook and Coho likely utilized the stream habitat for juvenile rearing habitat, with Chinook fry last captured in Hazeltine Creek in 2007 (n=38) (Minnow Environmental, 2009).

Historical information indicates lower Hazeltine Creek was not an important spawning location for Chinook (Minnow Environmental, 2007). Minnow Environmental (2007) indicated limitations to salmon productivity in Hazeltine Creek included the absence of deep water habitat during low flow conditions and the low pool-to-riffle ratio.

Coho Salmon *(Oncorhynchus kisutch)*

Coho Salmon spawn and rear in streams; however, lake-rearing (Swain and Holtby 1989, as cited in Roberge et al. 2002), pond-rearing (Dolloff 1993, as cited in Roberge et al. 2002) and lake-resident (Foerster and Ricker 1953, as cited in Roberge et al. 2002) populations occur in BC.

Spawning

Coho salmon age of maturity varies, with two years spent at sea the most common, but maximum age for coho is five years (Roberge et al. 2002). In BC, migration to the spawning grounds is usually between September or October (Fraser et al. 1983, as cited in Roberge et al. 2002). Spawning occurs between October and March, with some coho spawning shortly after arriving in the stream, others wait several months to spawn (Roberge et al. 2002).

Females select the redd sites. Redds are usually built in areas of medium to small gravel (Scott and Crossman 1973, as cited in Roberge et al. 2002). Gravel diameters range from 13 mm to 102 mm (Whyte et al. 1997). Preferred water depths are a minimum 0.18 m and water velocities range from 0.30 m/s to 0.91 m/s (Whyte et al. 1997). Spawning has been recorded for depths up to 5 m (Roberge et al. 2002). Coho salmon typically spawn in channels that are characterized by riffle-pool habitat with a gradient of 1-3% (Montgomery et al. 1999, as cited in Roberge et al. 2002)

Access to spawning areas in streams can be limited by channel gradient, elevation drops (e.g., cascades or falls), water depths and velocities. Adult chinook burst swim speed is 6.6 m/s (prolonged swim speed is 3.2 m/s) and maximum jump heights are 2.4 m with a jump height to plunge-pool depth ratios of 1:1.25 (Whyte et al. 1997).

Rearing

Coho salmon stream residency time varies. Coho typically remain in streams and rivers for up to two years (Whyte et al. 1997), but some migrate to sea as YOY fry, or spend all or a portion of their lives in freshwater (Quinn, 2005).

Newly emergent coho salmon young-of-the-year move to slower areas within the stream, such as side channels, near cover structures and stream banks (Tschaplinski and Hartman 1983; Bisson et al. 1988, as cited in Roberge et al. 2002).

Young-of-the-year and more so juvenile coho salmon feed on insects and young fish (Scott and Crossman 1973, as cited in Roberge et al. 2002).

Lethal water temperature for coho salmon is 25.1°C (Roberge et al. 2002).

Local Population

Lower Hazeltine Creek from the mouth upstream to the confluence with Edney Creek, has been identified in the Horsefly Sustainable Resource Management Plan as critical habitat (BC MFLNRO 2005). Species considered in the plan included Salmon, Bull Trout, Rainbow Trout, and Kokanee; however, it did not specifically state which of these species the critical habitat in lower Hazeltine applied to (BC MFLNRO 2005).

Local populations of coho salmon (Interior Fraser River stock), which have historically been observed in Hazeltine Creek, are identified by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) as endangered; however, the species is not currently listed on any Schedule under Species at Risk Act (SARA) and are therefore not protected under legislation (GoC 2014).

Coho salmon have historically been captured or observed in low numbers in lower Hazeltine Creek (n=9 in 2007). There was no spawner escapement data for Chinook or Coho Salmon (DFO 2014); however, a number of spawner surveys conducted in the 2000's recorded the presence of 12 Coho in Edney Creek in 2007. In a spawner survey of Hazeltine Creek conducted in November 2007, four Coho were observed, all within 125 m of the confluence with Edney Creek; however, no adult Coho were observed in 2008, although this may have been due to the timing of the survey (Cariboo Envirotech 2008; 2009).
